Epidemics of typhoid fever coincident with the finding of *B. coli* in normally pure waters, i. e., in waters known to be safe under ordinary conditions, but becoming dangerous by the accidental entrance of polluted water, have occurred where, although the entrance of this pollution was known, the danger was not indicated by chemical tests or by an increase in the numbers of bacteria beyond the usual limits of variation for waters of this class.

Report of the Committee on the Significance of Bacillus Coli in Water Supplies.

This report was read by the chairman, Mr. S. C. Prescott. To present a statement of the opinion of the committee individually and as a whole as probably representing the generally accepted views of sanitary bacteriologists as to the significance of *B. coli* in water, the following questions were sent

to each member. The answers appended, except as otherwise stated, were practically as given below. 1. In view of the fact that numerous investigators have found *B. coli* in nature where it could not be directly traced to sewage or fecal pollution, do you believe that the colon test of water is as safe an index of pollution as it was formerly regarded to be? Yes.

2. Are you of the opinion that the number of colon bacilli rather than their presence should be used as a criterion of recent sewage pollution? Yes.

3. To pronounce a water sewage-polluted, would you require as evidence that *B. coli* was present in a majority of one cubic centimeter samples? Yes, in general.

4. Are you in favor of recommending that the examination of large samples for *B. coli*, 100 to 1,000 c.c., be discouraged? Four members say "Yes" in reply, one says "No."

5. In case of a strong presumptive test, what confirmation tests would you require to make certain that the organisms present were *B. coli*? Full set of distinctive cultural tests.

6. In view of the probable presence of streptococci in polluted waters, do you think it desirable that they be isolated as well as *B. coli* to confirm suspicious evidence of pollution offered by *B. coli*? Two would not recommend this; one thinks it would be advantageous occasionally, but not practicable because of increase in routine work; one believes it should be done, when possible, for the sake of securing additional data, and for its general confirmation of the colon test; and one is indefinite.

A Simple Method for the Routine Detection of Colon Bacilli in Water.

Dr. William Royal Stokes, Baltimore, proposes the use of neutral red in a fermentation tube containing 1 per cent. lactose or milk sugar bouillon for the routine detection of colon bacilli in drinking water.

The work of Theobald Smith has shown that the colon bacillus ferments lactose with the production of from 30 to 50 per cent. of gas; that the medium is acidulated, and that the proportion of gas is usually that of one part of carbon dioxid to two of hydrogen. Jordan studied a large number of bacteria isolated from various rivers, and did not find any fermentive bacteria which carried out all of the phenomena in the lactose fermentation tube which is characteristic of the colon bacillus. The writer also isolated a moderate number of fermentive bacteria from the Baltimore water supply, and failed to find any fermentive bacteria exactly resembling the colon bacillus in lactose bouillon in the fermentation tube. In addition to the above characteristics of the colon bacillus in lactose bouillon, this organism causes a characteristic color reaction when neutral red is added to the solution in the proportion of 10 c.c. of a 0.5 per cent. solution to 1 liter. This has been partly described by Irons and others, but they use the test in an ordinary test tube. When used in the fermentation tube, the open bulb remains a port wine color, and the closed bulb a light canary yellow, often showing fluorescence. The curved stem joining the closed and open bulbs shows an abrupt contrast of the colors usually in the middle of the curve. The members of the proteus and cloacæ group usually turn both bulbs yellow, but not always. The method recommended is to inoculate a fermentation tube containing 1 per cent. lactose neutral red in the routine examination of water. If the percentage and amount of gas, the acidity, and the typical yellow-red contrast reaction all occur, the organism can be considered as *Bacillus coli communis*. This is a much shorter method than the isolation in pure culture, which takes from 5 to 7 days, and will also make it much easier to carry out quantitative experiments. These four distinct characteristics would seem to be sufficient to identify the colon bacillus in simple routine work.

The Bacterial Examination of 104 Samples of Water Together with a Detailed Study of the Colon Bacillus.

Dr. William J. Bissell, Buffalo, stated the results of an investigation as follows:

1. The amount of gas produced and the production of indol and putrefactive odors are not constant factors with even true colon bacilli; many of the lactic acid organisms bear a close resemblance to colon bacilli; and it is not safe to depend on presumptive tests alone in determining the presence of colon bacilli in the water.

2. In 104 samples of water from Niagara River examined at respectively 12 and 22 miles below a point where the sewage of over 400,000 people is received, colon bacilli were not found in all cubic centimeter amounts of the sample; there was a decrease in the number of colon bacilli the greater the distance down the stream; the heavy rains did not seem to increase the number of colon bacilli, although the land was used for farming purposes.

3. Colon bacilli can live in well waters at least 109 days, and the human variety seems to have a greater resistance than that from other sources.

4. In polluted water not all cubic centimeter amounts demonstrate the presence of the organisms. The writer believes that many organisms have been mistaken for the colon bacilli in water examinations.

5. There are many wells the waters of which do not contain colon bacilli, even though larger quantities are examined.

Isolation of Bacillus Coli Communis from the Alimentary Tract of Fish and the Significance Thereof.

Mr. George A. Johnson, New York City, said it has been shown that the colon bacillus is taken up by fish, and multiplies rapidly in the intestinal tract. A search of a large number of fish caught in an unpolluted water failed to reveal this organism in the intestinal tract. It would seem possible, therefore, that fish, having taken up the colon bacillus from a polluted water, might migrate to a water of comparative purity, where they would, naturally, discharge the greatly increased number of these organisms. Whether the finding of the colon bacillus deposited in a water in this manner would depreciate the value of the colon test in the examination of a public water supply is a question. It would certainly appear that if the colon bacillus can be thus easily transferred from one water to another that the transportation of the typhoid bacillus may be considered quite as likely. At least, the above results may explain the apparent phenomenon frequently noted where *B. coli communis* is found in comparatively large numbers in waters apparently open to but remote chances for fecal contamination.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Whitehead's Treatment of Gonorrhea.

Dr. W. H. Whitehead, Atlanta, Ga., whose article in the *Therapeutic Gazette* was reviewed in The Journal, November 7, page 1160, calls attention to our misunderstanding of one feature: His treatment is intended to be given by the physician only.

Argyrol in Gonorrhea.

R. O. Kevin, according to an abstract in *Med. Rev. of Reviews*, employs the following abortive treatment of gonorrhea if seen during the first twenty-four hours: After washing out the anterior urethra with warm water, two drams (8.00) of a 20 per cent. solution of argyrol are injected into the urethra and retained for ten minutes. This is repeated every three hours, day and night, for three days. According to the author 85 per cent. of the acute cases can be cured in from three to six weeks.

In chronic anterior urethritis or anterior-posterior urethritis, after irrigating with warm boric acid solution, a 20 per cent. solution of argyrol is applied to the urethral mucous membrane by means of a cotton applicator for two or three days. A 5 per cent. solution is used at the same time for irrigation.

In chronic posterior urethritis 5 to 20 per cent. solutions of

argyrol in lanolin are applied to the posterior urethra by means of sounds in addition to deep injections of the 10 per cent. aqueous solution every two or three days. In cases of cystitis, the bladder is irrigated with a saturated solution of boric acid, followed by a ¼ to 1 ounce (8.-30.) of a 10 to 20 per cent. argyrol solution injected into the bladder and allowed to remain. He recommends it in all chronic conditions of the cervix, urethra and endometrium as less irritating and more valuable than silver nitrate. It is non-irritating, and although containing 30 per cent. of silver it possesses greater penetrating powers than silver nitrate.

[In a recent discussion on the treatment of gonorrheal ophthalmia, W. T. Wilder presented its value in such cases as surpassing at present any other silver preparation. He employs it in 10 per cent. solutions to be dropped into the eye.]

Epistaxis.

In cases of epistaxis occurring in individuals with marked arteriosclerosis, according to an abstract in *N. Y. Med. Jour.*, mustard plasters may be used to the thighs, hot poultices applied to the back of the neck, and the arms should be elevated. As a snuff to check the hemorrhage the following is recommended:

℞. Antipyrini 3iiss 10
Cocainæ hydrochlor. .....gr. viiss 50

M. Sig.: To be used as a snuff to check nasal hemorrhage; or:

℞. Ext. hamamelidis exsic. .....gr. xv 1
Antipyrini 3iiss 10

M. Sig.: To be insufflated into the nares to check hemorrhage.

Hydrogen dioxid in its pure state is a valuable agent, also lemon juice or extract of adrenals (1-1,000), forty drops to half a glass of water. Tincture of iron is a very valuable agent used as follows:

℞. Tinct. ferri chloridi 3iiss 10
Aq. destil 3v 20

M. Sig.: To be applied locally to the nares; or:

℞. Gelatin 3iiss 10
Hydrarg. bichloridi .....gr. xv 1
Sol. sodii chloridi (7-100) .....Oii 1000

M. Sig.: Locally as an application.

A tampon saturated in the following solution is recommended, held in the affected nostril for five minutes:

℞. Cocainæ hydrochlor. .....gr. xv 1
Aq. destil. 3iiss 10

M. Sig.: Locally to the affected part.

To Reduce the Alkalinity of Urine.

Attention has been called by R. Hutchinson, in *British Med. Jour.*, to the value of acid sodium phosphate as an acidifier of urine. According to this author it has the greatest acidifying power of any preparation employed. It is a valuable agent in the treatment of cystitis, accompanied by the use of urotropin, which produces its best results in acid urine. The foregoing preparation is readily soluble in water, and may be given in doses of 30 (2.00) to 60 grains (4.00) every three or four hours if necessary.

Injections of Iodo-ether in Exophthalmic Goiter.

Abodie and Collon, in *Prog. Med.*, recommend the following combination as an injection in the treatment of exophthalmic goiter:

℞. Iodoformi 3i 4
Spts. etheris .....℥v 150

M. Sig.: Fifteen minims injected into the enlarged gland every second or third day.

By this mode of treatment improvement was noted in the headache, polyuria and neuralgic pains as well as a reduction in the rapid heart action and the tremor.

Adrenalin and Atropin.

R. Mengelburg, in *Annals of Ophthal.*, lays great stress on the fact that a combination of adrenalin and atropin is liable to produce symptoms of atropin poisoning, even in very small quantities. In several cases, although no idiosyncrasy to atropin was present when given alone, marked effects were produced by combining the two. His explanation is that through adrenalin the vessels of the mucous membrane of the canaliculus are much contracted and consequently the mucous membrane is made much thinner and the canal more patent, and in this way a larger opening is made through which the atropin can pass into the tear duct and from thence into the nose. He, therefore, advises extreme caution in using this combination.

Symptomatic Treatment of Phthisis.

The principal symptoms to be considered in the symptomatic treatment of phthisis, according to *The Pract.*, are the cough, night-sweats, occasional pains in the chest, digestive disturbances and hemoptysis.

COUGH.

In treating the cough it must be kept in mind that to a certain extent it is a salutary measure in that it tends to expel from the lungs a certain number of bacilli and other products. As a sedative for the cough at night the following combination is recommended:

℞. Liq. morphinæ .....gtt. iii 20
Vini ipecacuanhæ .....gtt. v 30
Oxymel scillæ .....gtt. xv 1
Theriacæ 3i 4

M. Sig.: At one dose for the cough, to be repeated as necessary.

Heroin may be substituted for the liquor morphin in the foregoing combination if preferred. In the early morning, if the cough is troublesome, much can be accomplished by the administration of some warm drink as hot milk or cocoa. During the day an inhaler may be used to advantage to check the cough and to disinfect the air passages. The following is of value as an inhalant:

℞. Olei eucalyptus
Spts. menthol
Spts. chloroformi, āā 3i 4

M. Sig.: Twenty to thirty drops to be inhaled three or more times through the day for half an hour or more each time.

THE NIGHT-SWEATS.

Tepid sponging at bedtime with an alcohol solution or vinegar water serves a good purpose, together with a drink of cold milk containing a little brandy. If this plan of treatment does not fulfill the needs the following pill should be given:

℞. Zinci oxidi ..... gr. ii-iv 12-.25
Ext. belladonnæ.....gr. ⅛-¼ 008-.015

M. Ft. pil. No. i. Sig.: One to be taken at bedtime.

Atropin sulphate gr. 1/100 (.0006) may be substituted for the foregoing, given hypodermically.

PAINS IN THE CHEST.

The pains are probably due to slight attacks of pleurisy. These may be relieved frequently by the application of some simple liniment or by painting the affected areas with iodin. The turpentine liniment proves effectual in most cases.

DIGESTIVE DERANGEMENTS.

It is of vital importance that the patient take as much nourishment as possible. To avoid digestive derangements a stomachic mixture such as the following is of service in improving the appetite and avoiding digestion:

℞. Tinct. nucis vom. 3i 4
Sodii bicarb. 3ii 8
Tinct. cardom. co. .....℥ss 15
Tinct. gentianæ co. q. s. ad.....℥ii 60

M. Sig.: Shake and take one teaspoonful three times a day.

If the digestion should then become disturbed the fatty materials should be cut down, give rest in bed and increase the elimination by the bowels by means of small doses of calomel.

DIARRHEA.

The diarrhea in phthisis may be simply due to overfeeding or otherwise to organic lesions in the alimentary tract, such as tubercular ulceration or amyloid disease. In the former instance a milk diet should be temporarily resorted to, and if

there are organic changes a starch and opium enema may be of use or the following combination given by the mouth:

℞. Plumbi subacetatis .....gr. ii |12
Liq. morphinæ .....m. v-x |30-.65
Acidi acetici dil. .....m. x |65
Aq. chloroformi .....3i 4|
M. Sig.: At one dose, to be repeated three times a day; or:
℞. Bismuthi salicylatis .....gr. xx 1|30
Sodii bicarb. .....gr. xv 1|
Mucil. acaciæ .....gr. x |65
Aq. menth. pip. .....3i 4|
M. Sig.: At one dose, to be repeated once or twice daily.

HEMOPTYSIS.

If necessary to check hemoptysis a hypodermic injection of morphin gr. ⅛-¼ (.008-.015) is probably the best treatment to quiet the patient and soothe the heart's action, which in turn aid in checking the hemorrhage. The patient should be instructed to lie quietly in bed, not speaking to anyone or even turning in bed. No food should be given for six or eight hours, when it should consist of cold or iced milk. Thirst may be relieved by sucking cracked ice. Ergot is not recommended on account of its tendency to raise blood pressure.

Calcium chlorid, gr. x-xx (.65-1.30), may be given to increase the coagulability of the blood. Turpentine is of value given as follows:

℞. Spts. terebinthinæ .....3ss 2|
Mist. amygdalæ .....3ii 8|
M. Sig.: At one dose.

If syncope should occur a teaspoonful or more of brandy should be given as a slight stimulant. The after-treatment of hemorrhage consists in correcting the anemia with preparations of iron.

Some authors recommend the following combination to check pulmonary hemorrhage:

℞. Stypticin .....gr. i |06
Plumbi acetatis .....gr. ii |12
Pulv. digitalis .....gr. i |06
Pulv. opii .....gr. ss |03
M. Ft. cap. No. i. Sig.: One such every four hours.

Aqueous Preparations of Menthol.

M. Cresantignes, in *Jour. Amer. Med. Sci.*, has found menthol to be a valuable anti-emetic given in an aqueous solution without the addition of a large amount of alcohol. To prepare an aqueous solution he recommends the following formula:

℞. Menthol .....gr. v |30
Tinct. quillajæ .....℥i 30|
Aq. destil .....℥v 150|
M. By dissolving the menthol in the tincture, add a small amount of glycerin and then add to the water in small quantities at a time. Sig.: Shake well and take two teaspoonfuls at a dose. Several teaspoonfuls may be taken at a time if necessary as the amount of menthol in each teaspoonful is very small. For external application the following combination is recommended:

℞. Menthol .....3v 20|
Tinct. quillajæ .....3iii 12|
Aq. destil. .....℥viss 200|
M. Sig.: To be applied as a wet compress for a few minutes at a time, followed by a compress of fresh water.

And as a gargle and mouth wash the following is recommended:

℞. Menthol |
Tinct. quillajæ, āā.....3i 4|
Solutionis acidi borici (saturated aqueous) .....℥vi 180|
M. Sig.: To be used as a gargle or mouth wash.

Employment of Heart Tonics Before an Anesthetic.

To overcome any cardiac enfeeblement which occurs in many patients previous to undergoing an operation, Feilchenfeld of Berlin, according to an abstract in *Medicine*, administers six drops of the tincture of strophanthus for two or three days preceding the operation. According to his statements too much stress is laid on the presence of valvular lesions and not sufficient attention given to the action of the heart. In individuals who are nervous and whose cardiac action tends to run up on slight provocation or where marked feebleness of pulse is shown, the administration of strophanthus or some similar heart tonic prior to an operation is very advantageous and important.

Medicolegal.

SOME LEGISLATION OF THE YEAR 1903.

Connecticut—Obtaining Treatment by False Pretenses.—Chapter 27 of the Public Acts of Connecticut of 1903 provides that any person who obtains medical or surgical treatment from any dispensary located in the state on false pretenses or representations as to his place of residence or as to his pecuniary circumstances shall be fined not more than $50.

Connecticut—Licenses of Other States—Re-examinations.—Chapter 71 of the Public Acts of Connecticut of 1903 amends section 4715 of the general statutes, on requirements for obtaining certificate of registration, adding the provision that any one of the examining committees appointed under the provisions of section 4716 may accept the license of any state examining board in lieu of an examination, provided the applicant shall present satisfactory evidence (1) that such license has been issued after an examination of as high a grade and of the same kind as required in Connecticut; (2) that he is a resident of Connecticut, or that he intends to permanently reside therein; (3) that he has been in actual practice for at least six months in the year immediately preceding his application, and (4) that he is of good moral character and professional standing. The fee will be $15. Section 4718 of the general statutes, relating to examinations, etc., is amended by striking out the words: "An applicant, rejected by an examining committee, shall not be eligible to re-examination until after the expiration of twelve months," and inserting in lieu thereof the following: "An applicant rejected by an examining committee shall not be eligible to examination before either of the other examining committees until after the expiration of twelve months, but may be re-examined by the committee before whom he appeared, at any subsequent meeting of said committee."

New Hampshire—Prohibits Spitting in Public Places.—Chapter 2 of the Laws of New Hampshire of 1903, entitled "An act to promote cleanliness and to protect the public from the disease commonly known as consumption," provides, among other things, that it shall be unlawful for any person to spit on any sidewalk, in the compact part of any city, village or town, or in any railway station, hall or other public place, or in any street or steam railway car other than smoking cars, except into spittoons or other receptacles provided for that purpose.

New Hampshire—An Act in Relation to Smallpox.—Chapter 45 of the Laws of New Hampshire of 1903 provides that it shall be the duty of every physician who attends any person whom he suspects is infected with smallpox to immediately report the same to the health officers of the town in which said person then resides, or if there be no health officers, then to the selectmen of the town, who shall immediately quarantine such person, and if there be doubt whether such person is suffering from smallpox, then said health officers or selectmen shall immediately notify the state board of health and request it to investigate the case immediately. If any physician, health officer or selectman neglect so to do he shall be fined the sum of $100.

New Hampshire—College Course to Count One Year.—Chapter 115 of the Laws of New Hampshire of 1903 amends section 7 of chapter 63 of the laws of 1897, entitled "An act to regulate the licensing and registration of physicians and surgeons," by adding at the end of the fourth requirement, which is that the candidate has studied medicine not less than four full school years, the provision that the regent shall accept "as the equivalent of the first year of the fourth requirement evidence of graduation from a registered college course; pro-

viding that such college course shall have included not less than the minimum requirements for such admission to the second year of a medical school registered as maintaining at the time a satisfactory standard."

New Hampshire—Sanatorium Treatment for Indigent Consumptives.—Chapter 184 of the Laws of New Hampshire of 1903, a joint resolution, authorizes the state board of charities and correction to send such indigent consumptive patients as are suitable for remedial treatment to a sanatorium for treatment, the board to pay for the care, treatment and support of such patients only the actual cost of their maintenance in the sanatorium. Persons in indigent circumstances, who themselves or by their relatives are able to pay part of the cost of maintenance, may be admitted to the sanatorium and maintained and treated therein at the expense of the state to that extent that they can not, by themselves, or relatives chargeable therefor, pay such cost of maintenance, when the state board of charities and corrections so certify and stipulate the proportion the state will assume and pay.

New Hampshire—State to Care for Dependent Insane.—Chapter 61 of the Laws of New Hampshire of 1903 provides that the state, from Jan. 1, 1909, shall have the care, control and treatment of all insane persons now cared for by the various counties; and no county shall hereafter establish any asylum or other additional structure for the insane, nor after said date maintain any institution for the insane, or be liable for the board, treatment, care or act of any insane person. From and after the passage of this act, the state board of lunacy may order the removal of all such dependent insane persons to the state hospital for remedial treatment as in their judgment seems proper, and such persons shall be supported at the expense of the state. After Jan. 1, 1905, as rapidly as accommodations can be provided, the state board of lunacy shall transfer from the various county almshouses to the state hospital such insane persons as in their judgment seem most suitable, such transfers to be made pro rata to the population of the several counties.

New Hampshire—Creates Office of Medical Referee.—Chapter 134 of the Laws of New Hampshire of 1903 provides that the governor shall nominate and, with the advice of the council, shall appoint in each county from one to three able and discreet men, learned in the science of medicine, to be medical referees in such county as they shall reside, who shall hold the office for a term of five years, subject to removal at any time for cause. When a medical referee has notice that there has been found or is lying within his county the dead body of a person who is supposed to have died by violence or unlawful act, he shall take charge of the same, and if, on view thereof and personal inquiry into the cause and manner of death, he deems a further examination necessary, he shall notify the county solicitor of the county, and on being authorized by the solicitor in writing, shall make an autopsy in the presence of two or more persons, one of whom shall be a physician whose attendance he may compel by subpena if necessary, and shall reduce, or cause to be reduced, to writing every fact and circumstance tending to show the condition of the body and the cause and manner of death, with the names and addresses of the witnesses giving evidence. If on such view, with personal inquiry or autopsy, the referee is of the opinion that the death of the person was caused by violence, criminal or otherwise, he shall at once notify the attorney-general and the county solicitor. He must also make return of the death to the city or town clerk. With the advice and consent of the attorney-general or county solicitor, he may, if he deems it necessary, call a chemist or other expert to aid in the examination of the body or of substances supposed to have caused or contributed to the death. The fees to be allowed shall not exceed, for a view and inquiry without autopsy, $5; for a view and autopsy, $25; and mileage. When it is deemed necessary by the medical referee and county solicitor to have a physician or surgeon present at an autopsy as one of the witnesses, such physician or surgeon shall be allowed a reasonable compensation to be audited by the medical referee and county solicitor.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

New York Medical Journal.

November 7.

1 *The Dwarf Tapeworm (Hymenolepis Nana), a Newly Recognized and Probably Rather Common American Parasite. Charles W. Stiles.
2. The Operative Treatment of Chronic Bright's Disease; a Second Communication, Based on Reports of 120 Cases. (To be concluded.) Ramon Guiteras.
3 *The Importance of the Physical Examination of the Abdomen as a Routine Practice Irrespective of What Be the Symptoms. Mark I. Knapp.
4 *Deep Breathing Richard C. Newton.
5 *Some Points in the Treatment of Hip-joint Disease. George B. Packard.
6 Some Principles on which is Based the Therapeutics of Electricity in Nervous Diseases. A. D. Rockwell.

1. Dwarf Tapeworm (Hymenolepis nana).—Stiles describes this parasite, and thinks it is more common in this country than is generally supposed. He has had probable evidence of its occurrence in various portions of the southern states and as far north as Washington and Philadelphia. Infection, he thinks, takes place through the infection of food by rats and mice, and, while as a local parasite the symptoms may be slight, the animal possibly possesses a toxin that plays a considerable part in producing serious infectious symptoms in certain cases. The diagnosis is somewhat difficult on account of the smallness of the parasite and the minute portions evacuated. The best method is to examine microscopically and find the characteristic eggs. The only drug that is of use in its treatment is male fern. Prophylaxis consists in cleanly personal habits; keeping mice and rats away from the food supply, and if a person is found to have the dwarf tapeworm he should sleep alone until he is rid of it.

3. Physical Examination of the Abdomen.—Knapp insists on the importance of thorough examination of the abdomen, and describes the methods of palpation and inspection.

4. Deep Breathing.—Newton sums up his paper in the following after showing the evil consequences of the practice of shallow breathing:

1. Deep breathing is essential to good health, and is in many cases a valuable therapeutic measure.
2. Its importance is not at all generally appreciated.
3. It should be a part of every child's education.
4. It is especially indicated for backward and sickly children.
5. The profession owes it to itself to study more deeply this vital question and to be able to instruct the laity fully on all its bearings.

5. Hip-Joint Disease.—The importance of allowing some functional use of the affected member in case of hip-joint disease is pointed out by Packard. He thinks that a certain amount of exercise should be employed as early as possible, and that this is preferable to the common practice of prolonged fixation and disuse. He suggests other points and insists on favorable surroundings, good hygienic conditions, diet, treatment of anemia, etc., as may be necessary.

7. Epidural Abscess.—Oppenheimer discusses the relation of mastoid disease and extradural abscess, the usual etiologic rationale being based on the thin wall separating the lining membrane of the mastoid cells from the meninges becoming necrotic. There may be other pathologic elements such as tuberculosis, etc. Epidural abscess is the most frequent intracranial complication of mastoid empyema, and may be the cause of the sinus infection or development of a brain abscess. Picqué and Ferrier claim that more than one-half of all the cases of epidural abscess arise from mastoid disease. The two most common sites for the development of pus collection are: (1) In the posterior fossa near the vertical

portion of the groove for the lateral sinus, and (2) in the middle fossa on the superior surface of the osseous tissue forming the roof of the antral cavity. If the mastoiditis travels backward the perforation will probably be through the thinner tissue above mentioned, while in some cases the tendency is upward and inward, and the abscess develops in the middle cranial fossa. The dangers are greatest when close to the sinus on account of the tendency to secondary inflammation and thrombosis. The symptoms may be non-characteristic, but if the local meningitis becomes sharply defined it may become of diagnostic import. In uncomplicated cases pyrexia is very slight or absent, as a rule. There may be headache and other subjective symptoms. When the abscess is extrasinuous there is generally a rise of temperature, and if aural disease will not account for the condition, intracranial complication should be suspected. If there is a high temperature at the beginning and other symptoms indicating epidural abscess, a complication of sinus thrombosis may be looked for. If the temperature is not high enough to suggest either thrombosis or meningitis, the question of cerebral abscess will have to be considered, but the absence of localizing signs and of subnormal temperature will aid in eliminating this factor. Localizing symptoms may occur from pressure on the brain, and head pain is one of the most constant and valuable symptoms, and is often limited. The pulse rate varies with the degree of associated meningeal irritation. Rigors are rarely present, and if they occur suggest a sinus complication. Optic neuritis is rarely found. Vomiting may occur with exacerbation of pain, also vertigo, but these latter have little diagnostic value. Under the best conditions the diagnosis is indefinite, and in many cases the surgeon can not determine the presence of pus before operation. The lack of high temperature, rapid pulse, irritability, etc., separate it from meningitis, as a rule. If the diagnosis is still in doubt in the presence of meningeal symptoms lumbar puncture should be performed. If it gives negative results, epidural abscess or sinus phlebitis, or both, are probably present. A bone fistula connecting with the cranial cavity is an indication of abscess, and a doughy swelling behind the meatus is significant. Cases are reported and a bibliography given. The infection in these instances was polymicrobic. The termination of an epidural abscess, if not recognized, will depend on the direction it takes in the destruction of tissue. It may point downward and spontaneously evacuate, but, ordinarily, neglect is dangerous. In recognized cases the prognosis as regards cure is favorable if the abscess is evacuated. No other treatment than surgical release of the purulent collection is to be considered.

8. **Precipitins.**—Ewing and Strauss' article is largely a critical historical summary of the facts from the literature. They, however, give briefly the results of some experiments on the changes in precipitin substances and the specificity of precipitins recognized. They find that in order to obtain the specific reaction in the human blood free from the danger of error from the personal equation they had to dilute antisera from the rabbits in their experiments, at least 1 in 30, and require a flocculent precipitate within three hours at 37 C. (This article is to be continued.)

9. **Immunity.**—Pottenger's article contains nothing specially new.

12. See abstract in THE JOURNAL of October 31, p. 1105.

13. **Hyaline Bodies in Tumors.**—Rosenberger has observed these bodies in malignant and benign tumors, in juice as well as in stroma, and sometimes within the cells, and describes their appearance. He quotes at length from the literature, and his conclusions are as follows:

It is seen from the specimens studied that these bodies were observed with great regularity.

They were in most cases quite deeply situated in the tissues, while a great many more were seen intracellularly.

Some of them gave quite a typical reaction of amyloid material, while the greater number failed to give this reaction. Treating them with dilute hydrochloric acid failed to produce effervescence.

It seems to me that they correspond most closely to the fuchsin bodies described by Russell, and that they really represent some degenerative change occurring in the cell or cell nucleus. That they play some part in the etiology of the conditions in which they are found seems doubtful, notwithstanding the fact that they are found deeply situated and intracellular. They do not possess the peculiar intracellular characteristics which Plimmer's bodies do, being distinctly hyaline. They may, however, represent a hyaline or amyloid degeneration of blastomycetes.

The fact that cultures were not obtainable in any case on various media and the failure to demonstrate true budding seems almost positive proof that they are not blastomycetes.

15. **Obstipation.**—Jelks calls attention to the various causes of obstipation, especially the extravisceral, including conditions of the uterus, prostate, etc.; perivisceral, such as cicatrices, tumors; visceral, including volvulus and neoplasms, and intravisceral, including intussusception, foreign bodies, fecal impaction and valvular obstruction. Each of these possibilities is briefly mentioned, the latter more at length. He thinks obstruction by Houston's valves is prolific of more trouble than all the other causes together, but he wishes to insist on the importance of recognition of the fact that other causes also may be considered.

16. **Nostalgia in the Tropics.**—Corson finds that the isolation and monotony, the depressing conditions of climate and the attacks of special diseases of the unacclimated persons in the tropics are conducive to homesickness and melancholia. He suggests frequent change of residence, sanatoria at high altitudes, prevention of self-medication and return home where practicable. He sums up thus:

Americans, owing to their strenuous mode of living and the depressing conditions of the tropical climate, are especially liable to nostalgia and melancholia.

Persons suffering from nostalgia should be watched, and when it is complicated by melancholia they should be advised to return home at once.

Sanatoriums at high altitudes, if not already provided, should be exploited at once for the recruiting of the health of soldiers and civilians. Only the government can do this.

An especial effort should be made to educate all persons residing there as to the best methods of living for the preservation of health.

21 *Internal Medicine, to What Extent Required or Elective in the Medical Course. S. G. Bonney.
22 *Observations on the Iodin Reaction in Children. Charles H. Dunn.

19. **Gastric Tetany.**—Moynihan reviews the symptoms and the theories of the cause of this condition, giving most favor to the auto-intoxication theory as being most in accordance with the facts observed. The possible reflex action from sensory stimulation of the stomach nerves may also have its part. The connection of gastric tetany with the condition of the kidneys is a matter also to be studied. The fatality of the disease is especially noted. It occurs so late in the conditions which give it rise that it is generally hopeless. Earlier adoption of surgical measures in chronic gastric ulcer, pyloric stenosis, etc., in the late stages of which tetany appears, would probably prevent its occurrence in many cases.

20. **Gastric Fermentation.**—Hewes has studied the conditions of gastric fermentation in a case which is reported in full, and finds four bacterial types existing which he thinks are responsible for the pathologic condition. They were as follows: (1) A coccus growing in small white colonies on the gelatin; (2) a short bacillus growing in small white colonies and giving evidence of gas formation on the gelatin; (3) a long bacillus growing in large creamy white colonies and liquefying the gelatin; (4) an organism growing in white colonies and answering to the morphologic characteristics of the sarcinæ ventriculi. These were observed only once. He has isolated all these in tube cultures. The first three produced alcohol and gas (CO_2) and some form of organic acid at some stage in the fermentation. It does not follow that these are the sole causes, but he thinks that future investigation of the subject, consisting in the identification and study of these

bacterial ferments, may give further results which will be reported in another article.

21. This article was abstraced in THE JOURNAL, xl, p. 1602.

22. **The Iodin Reaction in Children.**—This reaction, which was described by Cabot and Locke (see abstract in THE JOURNAL of Feb. 22, 1902, p. 519), has been tested on the blood of children in the Children's Hospital at Boston, and the results are given. Dunn finds that it is always present, usually of average, and often of marked, intensity, a high percentage of cells being affected, in the following conditions: Lobar pneumonia, bronchopneumonia, cerebrospinal meningitis, influenza, empyema, non-tubercular suppuration, and also in single cases of appendicitis, diphtheria and starvation. It is usually present in typhoid fever and miliary tuberculosis, but may be absent, and it may be present or absent in anemia. It is usually absent, but may occur in nephritis, cardiac valvular disease and tuberculosis. It is absent in pleurisy with effusion, functional indigestion, rachitis, articular rheumatism, congenital cardiac diseases, chorea, infantile atrophy, and was never encountered in single cases of bronchitis, eczema, purpura, urticaria and scorbutus.

27 Some Practical Points Taught by the Discovery of B. Dysenteriæ in the Stools of Infants Suffering from Summer Diarrhea. Louis M. Warfield.
28 *Hemospermia, with Report of a Case. Arthur L. Chute.

23. **Talma's Operation.**—Rosenstirn reports two cases. In the first an erroneous diagnosis of adenoma of the liver was the reason for the laparotomy. When the true nature of the hepatic cirrhosis was discovered, the omentum, gall bladder and liver were sewed up to the parietal peritoneum with good results. The second case was one of Hanot's cirrhosis; the operation planned deliberately and the condition of the patient fully reported. The results were also good in this case. The theory of the relief of obstruction of the blood circulation being not sufficient in explaining the effect of the operation in this latter case, Rosenstirn suggests the possibility of the deficient neutralization of toxins by the liver as a cause of the disorder. It is possible, he says, that there is in this disease primarily a hypertoxicity of the blood which, passing through the liver, causes new tissue growth, and the liver is unable to cope with the conditions. Obstruction in the biliary canaliculi and the consequent retention of the bile may furnish a special avenue for the toxins to reach the cardiac circulation, so that they can not be successfully fought except by establishing another more round-about method of circulation, which is furnished by this operation.

24. **Filariasis in Porto Rico.**—Ashford has observed the incidence of this condition in Porto Rico, and concludes that at least about 10 per cent. of the people are affected. He reports cases in the mounted battalion of the Porto Rican Provisional Regiment, showing that about 12 per cent. of the soldiers were thus affected, presumably before their enlistment. In 5 cases there was strong presumptive proof of this in the families; all had been exposed; all were young men; most of them three years in the service without serious illness, and they were from all parts of the island. All but 4 had had attacks of inguinal or femoral adenitis with chills, fever, pain and a red line in the inner aspect of the leg and thigh at varying intervals. Six had had chyluria. He thinks the people living in the crowded districts in Porto Rico are liable to the infection, and sleeping out of quarters is dangerous. While the disease perhaps is not often followed by very serious consequences, yet it is a serious menace to the subject.

26. **Rinderpest.**—Guthrie has observed the methods of inoculation immunization of cattle against rinderpest as practiced in Hong Kong by those supplying the carabao for the United States government at Manila. He finds that the disorder corresponds almost exactly in its type with acute dysentery in the human being. The inoculation is a simple one: 10 c.c. of virulent blood from another bullock with the disease in progress and 50 c.c. of prepared serum from an inoculated animal are injected. The inoculation is repeated in five days, sometimes in less time; sometimes two or three extra injections are given. It is hoped that by continuous working in this way an immune breed of cattle will be produced.

28. **Hemospermia.**—This condition of the ejaculation of blood-stained seminal fluid is an uncommon one. It is not in itself a disease, and usually gives more trouble to the possessor than it should, and may occur in the various disorders of the genito-urinary organs, or sometimes without any pre-existing affection. A case is reported by Chute and a number of others are cited from the literature. The prognosis varies with the nature of the lesion. In most instances it is due to chronic inflammatory lesions of the posterior urethra, prostate or seminal vesicles. The prospect for recovery is usually good; of course, if due to malignant disease the prognosis is bad. The treatment should be directed to the causative lesions. Massage is often a very important adjunct in inflammatory cases. The only case he finds on record in which treatment failed is one connected with the hemorrhagic diathesis.

29. **Injuries of the Spine.**—The statistics of the Cincinnati Hospital, and also the cases in his own private practice, are reported by Oliver, who insists on the importance of early operation in all cases where any evidence of activity on the part of the spinal cord exists. Good results where total abolition of function is present are not to be expected. The mortality is considerable, either with or without operation, and the majority of the patients remain paraplegics. Operation offers the only means of correctly demonstrating the condition. It may be successfully performed, he says, at a much later period than that formerly thought possible.

35 *Triceps, Biceps and Finger Clonus. Theodore H. Weisenburg.
36 *Studies on the Cerebral Cortex in the Normal Human Brain and in Dementia Paralytica. (Continued.) G. Alfred Lawrence.

33. **Spinal Tumors.**—The first case reported by Putnam and Elliott was that of a young man who had, as a sequel to an accident, a tumor in the cerebrospinal region at the level of the second and third cervical vertebræ, which caused paralytic involvement of all four limbs, of the costal muscles and even of the diaphragm. An operation was performed, and a tumor the size of an acorn, which was, pathologically, identified as a giant-celled sarcoma, was removed. The condition improved rapidly after operation, but suffered a partial relapse, and then a recurrence of improvement, so that at the present time the patient is in active life, and claims to be steadily gaining. There is a spasticity of gait and some restriction of the rotation of the head and considerable reflex excitability. It is noted as the first instance in which an operation has been performed for tumor at this level, and is important as showing what can be done even in so malignant a type as sarcoma and how long the tendency to recurrence can be delayed. The second operation was one for carcinoma of the last dorsal and upper lumbar vertebræ. It was decidedly relieved by operation, but the patient finally succumbed several months afterward. Both the patient and her husband admitted that there was a marked relief from pain after the operation

had been performed. The third case was one of fibrosarcoma in the lower cervical region encircling the cord and dura. A dissection was made and the growth removed. The dura was penetrated in one place and a large amount of cerebrospinal fluid escaped. The patient died five days after the operation.

34. **Brain Tumors.**—The method for the relief of pain here suggested by Browning consists in the administration of such depressants as aconitia, veratrum or gelsemium in doses sufficient to control the pulse, thus relieving, he claims, the intracranial blood pressure. It can not in every case and at all times stop pain, but it relieves it, and will often be all that is required for this purpose, even though the condition has existed for many months. He believes the classes of cases that it is likely to relieve are those where there is more or less general increase of the intracranial pressure, which occurs most typically in intrasubstantial growths. The pain is less intense, but more continuous. It may be still more useful in cases where there is paroxysmal augmentation of the arterial pressure with terrific pain seizures. Where, on the other hand, the pain is the result of the direct implication or stretching of the external structures, as the meninges and outgoing nerves, we have neuralgia and localized pain, and the good to be realized from depressants may be only proportionate to the amount in which the pressure is the factor. As far as he has observed in his practice with this method, no injurious effect has been produced on the course of the trouble itself. If anything, the life has been prolonged. The tendency to brain hemorrhage which exists in some of these cases is also favorably influenced by treatment. In cancer cases the use of depressants may also have a diagnostic value.

35. **Triceps, Biceps and Finger Clonus.**—These peculiar reflexes are not noted in many works on nervous diseases, and Weisenburg therefore calls attention to their occurrence. He has seen triceps clonus in a general paralytic; still more typical in hemiplegia in an alcoholic case. In this case there was also biceps clonus. Finger clonus was observed in a case of right-sided hemiplegia of long standing.

36. **Paresis.**—Lawrence's article is continued. The installment in this issue is entirely given to the pathologic findings.

41 The Inefficiency of the Wilde Incision. J. Morrison Ray.
42 New Laryngeal Instruments. Seth Scott Bishop.

37. **Maxillary Sinus Operations.**—Curtis goes at considerable length into the various operations for antral diseases. He favors the Luc-Caldwell operation as in many respects most satisfactory, but he also describes the operation through the inferior meatus, which has the advantage of requiring no anesthetic. It is performed by first cocainizing the inferior turbinate, cutting away its anterior third and bringing into view the outer wall of the meatus. He then makes a perforation with a trephine at a point a quarter of an inch above the nasal floor. As soon as the wall is perforated the trephine is changed for an olivary or barrel burr drill, enlarging the orifice upward, downward and backward. He then stuffs in some gauze wet with adrenalin solution to stop the bleeding, and by using properly curved, flexible ring curettes can reach the wall of the antrum very satisfactorily. He prefers the trephine for its ease in entering the wall of the meatus. He says he would favor a permanent drain for this region, since it can be useful whether the disease is local or connected with that in other diseased cavities. The article is fully illustrated.

38. **The Arch of the Palate.**—Swain has investigated the growth of the arch of the palate in a number of skulls, including those of Flathead Indians. His theory as to the cause of the arch is that it grows down with the growth of the skull. Nasal stoppage and mouth breathing tend to raise it by checking this growth. He says from a personal study we may conclude that it has been demonstrated:

1. That it is possible by deforming processes which artificially alter the shape of the skull to produce a change in form and shape of the hard palate. 2. That under these above-mentioned conditions the septum seems to conform itself to the altered development of the rest of the face, rather contrary to our previous ideas regarding the habits of this structure. 3. That if from arrested or retarded development of the superior maxilla, the palate fails to descend to its proper level, a bent septum is as liable to be produced as when the palate is arched too greatly by an unnatural narrowing process. Hence a palate of perfectly normal height as compared to breadth may produce a bend in the septum. 4. That in considering the various causes which produce the abnormalities of the palate, we must lay more stress on the lack of proper aëration of the maxillary sinuses retarding their development, and hence that of the whole superior maxilla. 5. The conservation and general care of the deciduous teeth help to produce a normal horizontal curve in the hard palate and lessen the tendency to narrowing.

39. **Cicatricial Deformities in the Respiratory Tract.**—Makuen endeavored by correspondence to find out the frequency of such deformities due to other causes than syphilis and traumatism, and reports his results. He found that 300 observers have seen 449 cases of cicatricial deformities not due to these causes. That 16 per cent. of these were caused by diphtheria, 8 per cent. by scarlatina, 3 per cent. by lupus, 1.6 per cent. by tuberculosis and 1.5 by scarlet fever and diphtheria combined, with 1.1 per cent. by typhoid fever and .5 per cent. by measles. Other causes mentioned are membranous rhinitis, catarrhal erosion, smallpox, scleroma, septal abscess, erysipelas and pemphigus. These facts, he says, emphasize the importance of giving more careful attention to the nose and throat in the treatment of the above-mentioned diseases.

48 *Recent Theories on Sound Conduction. Dr. Treitel.
49 Report on the Progress of Otology During the First Quarter of the Year 1903. Arthur Hartmann.

43. **Arrosion of Brain Sinuses.**—Eulenstein reports a case of mastoiditis following scarlet fever in which, in spite of early paracentesis, decay of the bone continued. The infection entered the cranial cavity, producing epidural abscess and corroding ulcer of the sigmoid sinus, perforation of which led to profuse and repeated hemorrhage. Direct plugging of the sinus was not sufficient, and he therefore shut off the blood current from below by tying the internal jugular vein, exposing the lateral sinus above its knee, and kept it compressed with the finger during the operation. He thinks he would recommend this method in other cases, not only to control the bleeding sufficiently, but also to control the primary affection thoroughly. He reviews the cases from the literature—18 in all, including his own.

45. **Cheesy Empyema of the Nasal Accessory Sinuses.**—Three cases are reported by Stieda in which large masses of cheesy material were removed from the nose. In one case there was almost a pure culture of bacillus coli in the mass; in others it was mainly amorphous material. He thinks that the other typical cases that have been reported in the literature, as well as his own, give evidence of the destructive nature of the caseous formation in these sinuses, and show that the process can be cured by drainage and thorough cleanliness.

48. **Sound Conduction.**—The criticisms of the Helmholtz theory of sound conduction are reviewed and passed on by Treitel, who discusses the literature. He thinks the attempts that have been made to overthrow this theory have not been altogether failures. The proofs as regards the method of resonance of sound waves are still unsatisfactory, and the very careful studies of Kleinschmidt and Zimmermann show that the resonance theory of the drum membrane of Helmholtz has become untenable. Moreover, from physical and physiologic facts, molecule vibrations must be admitted as

possible. If the molecular theory is correct, the middle ear mechanism is not absolutely necessary for sound conduction, but only for dampening loud sounds. The views are diverging also as to how the sound waves excite the fibers of the basilar membrane. It appears that this can be done by bone conduction alone, as in the case of loss of drum membrane and fixation of the stapes. He is in no doubt as to the value of Rinne's test in the diagnosis of ear diseases. Further research is still required to settle the questions that have been raised.

57 *The Mechanism of Occipito-posterior Positions; Does the Occiput Rotate Above or Below the Spine of the Ischium? Walter B. Gossett.
58 Gynecological Cases. W. E. Reed and E. K. Paine.

50. Abdominal and Pelvic Lymphatics.—Wakefield describes the anatomic structures and importance of these nodes in cases of malignant disorder. He insists on the importance of their thorough removal in cervical cancer, and sums up his general statements as follows: 1. The desiderata, in the order of importance, are: Removal of the uterus, removal of the parametric connective tissue, removal of the upper part of the vagina and removal of the regional lymphatics. Vaginal hysterectomy has no place as a curative operation in cancer of the cervix, and may be only palliative. The abdominal route, which should include the combined abdominal and vaginal, is the only one sufficiently radical to obtain the results that permit hopes of permanent results. He does not think any operation worthy of consideration that does not succeed in accomplishing at least the first three of these above-mentioned desiderata. The fourth will gradually grow out of the performance of the other three. The technical difficulties will, of course, be surmounted only by the experienced surgeon, and will not be popular even with him until with prolonged practice he has reduced the operation to a reasonable time limit and cut down the mortality rate. That operation will survive which permits the accomplishment of all the desiderata above mentioned with the least injury to the peritoneal structures, and at the same time affords the greatest protection to the ureter and important vessels.

51. Conservative Gynecologic Surgery.—While the results in Norris' total series of cases of surgery of the female pelvic organs are somewhat discouraging, generally speaking, and sometimes difficult to understand, very fortunate results have followed when he has carried conservative efforts to the extreme in some cases. No surgeon can predict the outcome. Future fertility depends more on the condition of the tube and success in restoring its caliber and integrity than on successful plastic work on the ovary. This latter rarely accomplishes the chief desire of the patient, namely, the relief from pain, and the patient who desires to be still fertile must be told that the preservation of the ovarian function may entail some condition of pain, often lessened, but still existing. Follicular cystic degeneration is very prone to be progressive. The age of the patient may help in deciding the case. A woman of 40 or more years of age, if she has children, should rarely be subjected to the risk of a second operation. The nervous temperament, recuperative powers, etc., have their influence. Women of strong nervous force and vigor, indifferent to pain, are the most favorable for successful conservative work.

53. Retrodeviations of the Uterus.—Stoner finds the shortening of the uterine sacral ligaments one of the most important measures in treating these cases. The following operation has been found by him so far satisfactory:

After freeing all adhesions and completing the necessary toilet of the adnexa, the uterus is brought strongly forward by the aid of a tenaculum forceps inserted in the fundus. This maneuver brings the uterosacral ligaments into prominence and each is transfixed, 5 or 6 cm. from its attachment to the uterus, with a needle carrying a medium fine silk ligature. Midway between the sutures and the uterus the ligaments are again pierced with a suture. After slightly relinquishing the hold on the tenaculum, traction is made on the sutures. The first or higher one is drawn downward toward the uterine attachment and anchored close to its origin to the uterus. The lower one is drawn upward toward the sacroiliac junction and attached to its fellow. Thus the ligament is folded on itself as in Mann's operation on the round ligament. A 1-500 solution of bichlorid of mercury should be applied to the edges of the folds to destroy the epithelium and cause adhesion; but care should be taken to wipe dry any excess of the solution. The ligaments must be shortened only enough to place the cervix in an easy elevated position. To aid in folding the ligaments, hemostatic forceps may be used to advantage for grasping the traction suture close to the ligament. The operation is completed by whipping together the folds with fine catgut. The operation of itself is sufficient to hold the organ securely. However, as a matter of precaution the round ligament should be shortened by one of the standard methods. No operation for the cure of this affection is complete, however, without due attention to all complications, such as damaged pelvic floor, lacerations of the uterus, endometritis, etc. Shortening the utero-sacral ligaments I believe to be an ideal method for the cure of retrodisplacement. The operation is simple and is usually easily accomplished It is productive of no danger of bowel obstruction or pregnancy disorders, two very important points to consider in making up one's mind as to the best operative procedure.

57. Occipito-Posterior Positions.—Gossett holds that the occiput can not rotate forward after it passes posterior to the spine of the ischium. As the head descends in the R. O. P. position by the force of the uterine contraction it is first flexed to allow the head to enter the brim, substituting the sub-occipito-bregmatic diameter of the head for the occipito-frontal. The force of uterine contraction is transmitted through the vertebral column to the short pole of the fetal head, the occiput, producing more flexion. The head descends and the occiput, being the most dependent part, meets the resistance of the pyriformis muscle and soft parts which starts its rotation to the front, it rotating away from the point of resistance to that part of the pelvis where it has the least resistance, that is, to the right and forward. This is the beginning of the second step of labor in the R. O. P. position with a favorable termination, that is, the rotation of the occiput through three-eighths of a circle to the front. If the resistance of the pyriformis muscle and soft parts is not sufficient to start the rotation of the occiput to the front, then it will pass on down and fall behind the ischial spine and onto the right posterior inclined plane, following its direction, which is downward and inward to the hollow of the sacrum.

70 Tropical Abscess of the Liver. Ernest F. Robinson.
71 *Intestinal Localization. George H. Monks.
72 A Further Case of "Hour-glass" Stomach. John M. Elder.

59. Malignant Edema.—Malignant edema produced otherwise than by the Welch bacillus is rare. Gould has found only 5 cases in the medical literature, not one in the English language, and therefore the case he reports he thinks is of interest. There are 3 cases that are reported in addition to the 5 mentioned, but he considers the bacteriologic evidence insufficient. He describes the bacteriologic findings and the culture results.

60. Hemorrhage from Trephining.—The case of Ransohoff and Phelps was one of almost inevitable fatal hemorrhage. In using the electric fraise for the osteoplastic operation the bleeding from the bony canals was so excessive that the patient died on the table. The diploic canals were greatly enlarged, and whether another method would have had better

results is questionable. Posture of the head and compression of the carotids were without avail.

61. **Aneurism Treated by the Matas Method.**—Morris reports a case of fusiform aneurism in the popliteal region which was operated on by the Matas method of opening up and clearing out the clot and making a new arterial channel for the blood, with excellent results. As soon as the sutures were completed and the elastic bandage removed pulsation appeared and there was no leakage; the paralyses of sensation and motion which had resulted from the presence of the aneurism began to disappear. Sensation was well defined over the right leg and foot by the seventh day. On the twenty-second day there was still a little paralysis of motion in the anterior tibial region. The restoration of function is satisfactory.

64. **Calculous Anuria.**—Two cases are reported by Cabot. In the first the calculus was dislodged and forced on to the bladder by massage applied through the abdominal wall. He recommends this procedure as a frequent practice, though it should never lead to delay of operation during an uncertain period of diagnosis. In the second case the operation did not reveal a stone, but the subsequent history of the case showed that two small ones were washed out from the bladder with the Bigelow evacuator, and a large one crushed and pumped out under cocain anesthesia. Recovery was uneventful. The stones were evidently forced into the bladder by manipulation of the ureter during the operation.

65. **Perineal Section.**—The method here described by Gibson consists in using a rectal speculum and pulling down the prostate with a tenaculum, traction being exerted downward and somewhat backward. When median perineal section is performed the forefinger is introduced into the wound and as an assistant gently tugs on the hook one readily receives the sensation of the intermittent tension of the urethra in response to the traction on the prostate, thus guiding further incision. The danger of infection from puncture of the prostate through the rectal wall he thinks is minimal. In none of his cases has there been any such bad result. He does not recommend this as a routine operation, but it should be reserved for cases where there are unusual difficulties, a feeble patient, especially one with diseased kidneys or other complications. In septic states due to urinary extravasation, the very slight risk of infection (which, if it occurs, can easily be attacked through the existing perineal incision) may wisely be taken in order to increase the patient's chances.

66. **Tuberculosis of the Female Urinary Tract.**—Fourteen cases are reported and tabulated by Ill and their interesting points commented on. In only one case did the disease seem to have started in the bladder. The resistance to the tubercle bacilli of this organ seems to be so great that it will sometimes throw off the disease itself, as is demonstrated in his second case. Resection of the secondarily diseased portion is not necessary. Even the ureter may sometimes recover spontaneously, as is shown by another of the cases. He does not, however, advise leaving an infected ureter. He holds that these cases show that bladder tuberculosis is usually propagated by contiguity instead of by the blood current. Other cases show the possibility of recovery after long periods of time, as well as the rapidly fatal termination in some instances.

67. **Pyosalpinx.**—Coffey has developed from his experience a technic as follows:

After the abdominal incision has been made, first see if it is possible to push the intestines upwards towards the diaphragm, and hold them by packing in gauze sponges; second, seek the fundus of the uterus. Having made way to the uterus, gradually insinuate the finger along the posterior surface until the cul-de-sac has been reached. Carry a gauze sponge down between the fingers and the uterus. From this point of cleavage separate adhesions from the center as much as possible, gradually filling the space made with the gauze sponges. As fast as possible separate adhesions of the intestines and push them back towards the diaphragm until they are well out of the way and a thick wall of gauze sponges separates the field of operation from the general abdominal cavity. Now gradually separate the adhesions, holding down the tubes, and lift the uterus as high as possible with vulsellum forceps. . . . . The first step in the actual operation is to exsect the tube by a V-shaped incision in the cornu of the uterus. . . . . Follow this up with a continuous catgut until the V-shaped incision has been almost closed. Put down this needle and thread; lift the tube as high as possible; ligate the web or ligament of the tube in three or four different sections with catgut, as close as is consistent. A certain amount of comparatively healthy and active ovarian tissue may be found at the base of almost every ovary, no matter how cystic. Remove all the cystic portion, making, if possible, a V-shaped incision, which is to be closed with a very fine catgut. . . . . Now take up the needle and continuous catgut suture which has been used to close the V shaped uterine incision, pass the needle through the peritoneum just external to the line of stumps, then the side of the uterus, then through the peritoneum, back to the side of the uterus, and so until the peritoneum forming the web or ligament of the tube has been brought in contact with the side and back of the uterus. After this has been done, it is found that the raw stumps are hidden and in contact with the back and side of the uterus. The ovary is suspended by its normal ligament under a roof made of the peritoneum of the broad ligament, and is thus protected from contact with the intestines above. The other tube and ovary are treated likewise. Owing to the fact that very many of these cases tend to retroversion of the uterus, I have supplemented this part of the operation by what I have called for want of a better name, posterior advancement of the round ligament, which is done by seizing the round ligament an inch or an inch and a half from its uterine attachment and bringing a knuckle backward to be stitched to the posterior and lateral surfaces of the uterus and broad ligament by a line of catgut sutures. This holds the uterus in its normal position. In the great majority of cases every raw surface may be covered up by this method. If there should be infection of the ovary or in the stump following the operation, there is but one place for an accumulation to take place, namely, in the cul-de-sac, where it will do the least possible damage and be most easily reached.

He holds drainage unnecessary except in acute cases, as the pus is generally sterile and when required it is better to drain through the cul-de-sac. He usually employs the compound drain of rubber tube and gauze as being the most satisfactory. The advantages of his method he sums up as follows:

1. Small mortality. 2. The covering of every raw surface with peritoneum as far as possible, and directed so that drainage will be into the cul-de-sac. 3. Future complications and adhesions are almost altogether prevented by exsecting the tube from the cornu by a V-shaped incision, suturing the incision with catgut and bringing the peritoneum of the broad ligament and the stumps in contact with the uterine body. This turns the ovary and raw surfaces into the cul-de-sac, sheltered by overlying peritoneum, and all broken areas are brought into the cul-de-sac within easy reach in case of infection of either the uterus or remaining ovarian tissue. 4. Owing to the tendency of the uterus to be drawn backward by adhesions, the posterior advancement of the round and broad ligament serves a valuable purpose. 5. No vessel is tied which under ordinary circumstances could cause fatal hemorrhage, even though all ligatures slip. 6. All the normal womanly functions can be kept up except childbearing in almost every case.

He believes the method a useful one in conservative surgery. The article is profusely illustrated.

71. **Intestinal Localization.**—Monks has studied on the cadaver the characteristics of the intestine at various distances from the duodenum, and gives his results. He utilized for differentiation the root of the mesentery, which springs from the posterior wall of the abdomen along a straight line six inches in length, starting above on the left side of the spinal column where the duodenum ends, and about on a level with the body of the second lumbar vertebra, continued obliquely downward and to the right, to end in a somewhat indefinite way at a point opposite the sacro-iliac synchondrosis. The circulation in this mesentery is one of the valuable points in the localization of the intestine. The arrangement of the main branches of the superior mesenteric artery is in primary and secondary loops; the former predominating and being more marked in the upper end, and the circulation becoming more complicated as we descend. There seems to be no fixed rule as to the length of the intestine. Age and sex have little to do with it. Where the intestine is very long he has sometimes found the mesentery also of unusual length, and the little straight vessels running from the mesenteric loops to the intestines much longer than the average. Where it is short he has also observed in a few cases that the mesentery and vasa recta were also short. The diameter of the gut is the greatest above, and gradually diminishes in size as we go down the tube. In the lower third or so the size remains the same throughout. The thickness is greatest in the upper part on account of the large and numerous valvulæ conniventes and the greater development of the muscle layers. It gradually gets thinner until within two or three feet of the cecum, where it thickens again. This thickening is presumably due to an increase in the muscular elements. The upper part is normally bright pink or red, showing numerous vessels. As we go down the tube the color changes to a gray or pinkish or yellowish gray and the vascularity is less marked. The valvulæ conniventes diminish in number as we go down, and about fourteen or fifteen feet from the end of the duodenum they

seem to disappear, and below this can seldom be seen or felt. The various parts of the intestine show foods in various stages of intestinal digestion. The consistency increases somewhat towards the lower end. It is hardly necessary to suggest that when one end of the loop, which is high up in the bowel, is gently pulled on and meets with resistance the loop is probably close to the duodenum, and likewise when one low down in the bowel meets with resistance the loop is probably a short distance from the ileocecal valve. The mesentery varies in thickness in the different parts. The thinnest part of the mesentery is that portion which is adjacent to the upper part of the intestine, and it becomes thicker as we go down the tube, largely owing to the deposition of fat. Its translucency varies immensely. Tabs of fat near the mesenteric border of the intestine are another guide, increasing toward the lower region. The direction of the stretched mesentery may also be a guide. Knowing the direction of the line of resistance, we get an approximate idea as to the part of the mesenteric root which resists; we can generally tell whether it is to the left or right. The more it inclines to the left from below upward, the nearer is the loop to the duodenum, and vice versa. These conclusions which he reaches are only approximate ones. He gives a fair average showing that he was within three feet of the true localization in about 75 per cent. of his estimations, and that the average was not out more than 2 feet.

79 Some Mistakes of a Country Doctor.

77. Intubation.—Long describes his methods of intubation, insisting on the importance of frequent practice on the cadaver before attempting it on a living person. He mentions one little point of invaluable assistance to him. As soon as it is felt that the end of the tube has entered the larynx pass the finger quickly into the esophagus. If the tube is properly engaged the posterior laryngeal tissue will be felt between the tube and the finger, and we know that the tube is not getting into the esophagus. With this assurance push the tube gently home, following it as one would an urethral sound, for here, as in the urethra, there is danger of making a false passage or other injury. This precaution of feeling the posterior wall of the larynx is not, he thinks, mentioned in any text-book, but it is of special value, for, if observed, many of the difficulties of intubation would disappear. He thinks it would be better to remove the string as soon as it is seen that the larynx tolerates the tube. Feeding the patient is sometimes difficult at first. The child can swallow better lying down or even with the head hanging low. Sometimes forced feeding with the tube will be required. Extubation is in some respects more difficult. Some operators leave the string, others use external pressure to push the tube out. He remarks that one of the physicians of a hospital in Philadelphia told him that he considered it favorable when the tube was coughed up as it avoided the trauma of extubation. As regards retained tubes he thinks the average time can be estimated in days rather than in months. Fortunately the necessity of keeping it in longer than the normal period is rare. A number of cases are reported, and the results were 11 lives saved out of 13, or a mortality of only 15.33 per cent., which can be greatly improved on. In fact, a 5 per cent. mortality may be safely taken as the average.

83. Cutaneous Innervation in Man.—From his studies of the nerve fibers in the anterior roots and estimates based on others' work, Ingbert concludes that about 79 per cent. of the medullated nerve fibers in the dorsal roots of both sides, or 1,032,730 fibers, go to innervate the dermal surface, and about 21 per cent., or 274,521, are afferent fibers distributed to the muscles and deep tissues. The afferent fibers of spinal ganglion origin passing in the *rami communicantes* are not separately considered here, but are classed with those passing to the skin. According to his estimate (using the skin areas for a large man), one cutaneous nerve fiber in the dorsal spinal roots innervates, on the average, 1.08 sq. mm. of the skin of the head and neck and 3.15 of the skin of the trunk. For each additional class of nerve fibers assumed we must increase the area proportionately. If we assume, with Foster, four classes of cutaneous nerve fibers, then each fiber will have to innervate on the average 4.32 sq. mm. of the dermal surface of the head and neck, and 12.6 of the dermal surface of the trunk. If there are four classes of afferent nerve fibers in the dorsal roots, then a histologic examination of the nerve terminations in the skin ought to show each cutaneous nerve fiber to innervate average areas as large as those given above. He attaches a bibliography.

2. **Malignant Disease of the Larynx.**—Semon thinks the intralaryngeal operation does not offer the least guarantee that a due amount of healthy tissue is removed. Thyrotomy is preferable if performed in the early stages of intrinsic malignant disease. It should be thorough and no sentimental considerations must interfere. Experience has shown him that often in cases of extensive disease without removal of the growth and soft parts around it subsequent energetic scraping of the base is sufficient to prevent recurrence. It is only when the cartilage is invaded that its removal is required. As regards total extirpation of the larynx he corrects the impression which has prevailed that he was an opponent of this operation; he advocates it when it is indicated. Subhyoid pharyngotomy is suitable for cases where the disease starts from the epiglottis or from the aryteno-epiglottidean fold. The technic is easy, but there has been a curious fatality in this operation. Palliative tracheotomy ought only to come into question when the disease has started in a locality where nothing short of total extirpation of the larynx could come into play and the patient declines that operation, or when the disease, starting in a better locality for the milder procedures, has not been recognized early enough to allow them to be employed or when serious complications forbid their employment. If it has to be performed it should be done as low down as possible. In conclusion he remarks in regard to the possibility of a reliable diagnosis and points out the difficulties.

Gluck followed Semon in the discussion and described his own methods. For diffuse papilloma, some cases of syphilis and circumscribed cancer of the vocal cords, he would make a low tracheotomy, expose the larynx through a median incision, divide the thyroid cartilage and the crico-thyroid in the median line and retract the halves. Then remove the growth with the scissors, knife, or thermocautery under cocain, putting in plugs of iodoform gauze and suturing to the cartilage. These can be removed in four or six days under anesthesia. If necessary the suspected region is cauterized and the wound stitched up. About the tenth day the sutures are removed and also the tracheal cannula. The third week healing is complete. His results have been excellent with this method. In cancer of the larynx and with tumors of the tongue and pharynx he has escaped the source of danger of inspiration pneumonia by resecting the trachea and stitching the distal cut end of that tube to a buttonhole in the skin, thus preventing the possibilities of foreign bodies reaching the lungs. Gluck also describes his method of hemilaryngectomy and total laryngectomy and extirpation of the larynx or pharynx, or both, reporting cases. His remarks are amply illustrated. His most recent results show a series of 22 complete laryngectomies with 1 death; that in a feeble old man. Of partial extirpations of the larynx and pharynx, generally combined with removal of infected glands, he has a series of 27 cases with only 1 death. In this the carotid had been tied and the death occurred from hemiplegia five days later. His principles are, first save and prolong the life of your patient and do not worry about the postoperative state. Restitution of function will be a secondary care.

4. **Suppurative Middle-Ear Disease.**—McBride's paper is chiefly historical as regards mastoid operation and intracranial suppuration. He reports illustrative cases.

5. **Nasal Polypi.**—Bronner, in case of nasal polypi, removes as much of the growth or diseased mucous membrane as he can with the cold snare and then applies formalin on a probe to the roots. He tries not to cut through the pedunculated polypi, but to pull them out by the roots. In this way he often succeeds in removing the whole, and in many cases part also of the underlying diseased bone. Before using formalin he again applies a powder consisting of equal parts of cocain, eucain and desiccated suprarenal extract to the parts. After a few days a formalin spray of 1 to 500 up to 1 to 100 is ordered to be used three times a day for a week or two and then less frequently. If this is painful he orders a paroleine spray to be used. Formalin is a powerful disinfectant, but also causes contraction and hardening of the diseased tissues. He also uses insufflations of tannoform, aristol and boric acid. As long as there is much discharge an alkaline spray should be used. The middle turbinate is often extensively diseased. He removes the anterior part by the forceps or snare. A careful examination of the nares and the reduction of the swelling by a local application of cocain and desiccated suprarenal extract enable a correct diagnosis to be made. This is his method in all cases of polypi. He is inclined to think that nasal polypus is most often an extension from disease of the accessory sinuses.

7. See abstract in THE JOURNAL of September 12, p. 679.

9. **Cancer of the Larynx.**—In extrinsic cancer with the disease still very limited it may be removed, Moure says, with the snare or cutting forceps under cocain and adrenalin. When it is situated further down, involving the epiglottis, base of the tongue and perhaps even the glosso-epiglottic folds, an external operation is required. For this he prefers transhyoid pharyngotomy, as recommended by Gussenbauer and revived by Vallas. The operation is easy. He opens from just behind the chin, backward to that point of the trachea where the cannula is to be introduced, dividing the tissues layer by layer in the middle line; also the hyoid bone if necessary. By drawing the two halves apart the epiglottis is easily exposed, and it is then drawn forward in the wound and removed. An energetic application of the curette and the thermocautery completes the operation. The two halves of the tongue are then sutured with catgut, the parts of the hyoid bone are held together by stitching the muscles above it and below, and finally, the skin is stitched with horsehair. He thinks it better to leave the tracheotomy tube in for some days, but it is not necessary to feed the patient through a tube. His patients have experienced no trouble in swallowing. The operation is an ideal one, as it gives access for the removal of infected glands, though it will not, of course, prevent recurrence. In intrinsic cancer thyrotomy is beneficial in cases of malignant growth originating in the interior of the larynx and especially of tumors of one or the other of the vocal cords. When one of the ventricular bands is affected and peripheral infiltration exists, or, still more, when the corresponding arytenoid cartilage is fixed, or there are signs of perichondrial disease, this method is unsuitable and should be rejected. He describes his methods at length. When the tumor has extended beyond the limits described, a partial or complete laryngectomy will be required.

19 A Case of Cutaneous Neuro-fibromatosis in which Newly Formed Nerve Fibers Were Found in the Tumors. Arthur Whitfield.

10. **Climacteric Insanity.**—The mental disturbances of the climacteric period are largely dependent on the neurotic predisposition, and are more frequent in single women and widows than in married women. The number of women who take to alcohol at this period is remarkable. There is a feeling of languor and inability to do what they want, and the taking of a little "pick me up" develops into a habit. Drug habits also develop about this time. In many cases the natural symptoms develop into delusions, self-consciousness is increased, and there is morbidity with impulsive and passionate acts or even suicide or homicide. A neurotic excitability is often noted and such conditions as kleptomania, hysterical developments, a tendency to lying accusations. Most of the cases are of the depressed type, with ideas of persecution, watching, etc. A late pregnancy occurring about or near the menopause is sometimes the cause of the mental trouble. Next to melancholia, the delusional characteristic is probably the most frequent. Ordinarily, one might say that if a patient did not get well in a year the chances are unfavorable, but with climacteric insanity it is impossible to give a definite prognosis as to recovery or the permanency of the disease. Probably there will be no improvement. If dementia appears it will become more pronounced, but there are occasional cases of remarkable late recoveries from this form of disorder.

11. **Carcinoma of the Colon.**—The points that Walsham emphasizes in this article are that columnar-celled sarcomas are the most benign forms of cancer that exist. At first the growth is localized to the bowel and has not affected the lymphatics, and if taken early enough the patient may be cured or the life prolonged a number of years. He has had cases where there has been no recurrence for about eight years. The symptoms are indefinite abdominal disturbances, uneasiness after eating, flatulency, a history of constipation with eructations, nearly always liquid stools, slowly progressing loss of weight and an almost constant desire to defecate. The rectum should be examined first, and this procedure may reveal the whole trouble. He would go thoroughly into the case, and says one should not assign the trouble to indigestion, but should watch and weigh the patient from week to week. If there is no improvement, examine the rectum and abdomen under an anesthetic, and if there is still no improvement make an exploratory incision, which will do no harm and may do a great deal of good. When an operation is to be performed the best plan is to do it in two stages: (1) Colotomy; (2) resection of the bowel and removal of the growth, uniting the ends of the bowel together with a Murphy button. After good union of the intestine close the colotomy wound and let the bowel resume its function. He advises against taking a wedge-shaped incision out of the mesentery, preferring to go along the edge of the mesentery and not to disturb the nutrient vessels.

18. **Puerperal Fever.**—An adjunct to uterine irrigation is described by Watson. After douching the uterus, express as much of the solution as possible, then inject into the cavity one ounce of glycerin containing 3 per cent. of formalin. This is quite innocuous and non-irritating and, in addition to its powerful antiseptic action, it removes all the water from the uterus. Its use prevents any rise of temperature following the douche which is sometimes observed under ordinary treatment. The whole procedure must be carried out with the strictest antiseptic precautions. Two cases are reported showing the results.

20. **Kerosene as a Culicide.**—Gray finds that kerosene is not an absolutely successful culicide for the adult anopheles. Only a small proportion were killed by it, and it did not prevent them from laying eggs, though it has excellent results in preventing the development of the larvæ. Crude petroleum is more viscid and more likely to be efficient.

21. **Yellow Fever.**—Gray mentions the possibilities of stegomyia developing on steamers and being carried by them. He does not think, however, basing his views on Guiteras' experiments, that yellow fever is transmitted from insects to their offspring.

27 *A Generally Unknown Source of Enteric Fever. W. Beevor.
28 Adrenalin and Its Uses in General Surgery, Especially Applied to Ophthalmology. Henry Gildney.

24. **Perineal Litholapaxy in Children.**—The indications for litholapaxy in adults and in children are the same, according to Garvie, who recommends the perineal method in young cases in preference to lithotomy. The only direction necessary to give, he says, to those unfamiliar with the operation is to measure the extent of one's incision in the deeper parts with a probe and, having satisfied oneself as to its sufficiency, to remove all instruments and gently insinuate the lithotrite. No force is required. There is no bruising or tearing of the tissues from crushing of the stone. The wound heals in about one week. He would ask the surgeon to use this operation frequently instead of the ordinary litholapaxy.

27. **Enteric Fever.**—Beevor calls attention to the danger of acquiring enteric fever from baths, especially in India. Few people seem to be aware of this possibility. Water may enter the mouth or nose and in this way produce infection. He advises the careful avoidance of any inhalation or swallowing of the water in the bath and careful washing of the teeth and gargling of the throat afterward, using a strong antiseptic tooth powder, and plenty of it. These precautions apply to those who bathe in rivers or streams, especially soldiers in active service.

30 *Sleeping Sickness. R. Blanchard.—Présentation de 3 nègres du Congo, atteints de la maladie du sommeil.

29. **Dwarf Growth To-day and in the Past.**—Poncet presents arguments to prove that the traditions of pygmies in the remote past related to the advance guard of the human race, who were diminutive in stature. Recent discoveries of skeletons of dwarfs in the prehistoric burying places, their numbers during ancient and medieval history and the few specimens known at the present day, all confirm the assumption that they belonged to a special race, numerous in the early days and gradually becoming extinct. Rome had battalions of dwarf gladiators, and as late as the tenth century dwarf races were known to people Switzerland, Alsace, etc. Nuesch and Kollmann maintain that they were the original inhabitants of Europe. Poncet has recently examined two dwarfs, brother and sister, both healthy and intelligent, whose father and grandfather had likewise been dwarfs. Radioscopy shows that the epiphysial cartilage must have become united to the shaft at the normal date, while in ordinary dwarfs this union does not take place and their achondroplasia is pathologic. In the ancestral pygmies the ossification proceeds normally, only the epiphysial cartilage is physiologically and relatively unproductive.

30. **Sleeping Sickness.**—Blanchard exhibited three negroes from the French Congo, and stated that Brumpt who had brought them had observed 38 cases. In 32 of these he had isolated a trypanosoma from the cerebrospinal fluid. He found a fly, the glossina, invariably present where there are cases of sleeping sickness, and thinks that it is probably the obligatory intermediate host. The immunity of certain countries may be due to the absence of this glossina.

37 La dichotomie jugée par un chirurgien allemand.

31. **Role of the Leucocytes in Absorption and Distribution of Medicinal Substances.**—Labbé relates experiences which demonstrate that soluble substances are merely absorbed by the protoplasm of the phagocytes and chemical or physiological tests will reveal their presence. Insoluble substances are likewise taken up but undergo a transformation. Arsenic is broken into minute particles, transformed and rendered soluble. Calomel is split into metallic mercury and a bichlorid. This transformation occurs under the influence of the active ferments in the body of the leucocytes, the oxidases. When this transformation is complete the drug requires more complex tests to detect it, and the preliminary destruction of the albuminoid or nucleinic molecule. The research described confirms the superiority of the subcutaneous route over ingestion by the mouth for certain drugs. The insoluble salts become soluble by the mediation of the leucocytes. This occurs slowly and progressively, which explains the tardy and prolonged effects of injection of the insoluble salts. The leucocytes are also attracted to the site of a morbid process and thus carry to it the drug injected, but we must not forget that the drugs themselves have more or less affinity for certain tissues, and display a marked localizing tendency, characteristic for each chemical substance, and which needs further study.

34. **Opening Up Posterior End of Urethra Through Perineum.**—Forgue has performed this operation by the technic described in 3 cases of impermeable fistula of the urethra, going at once to the vesical end of the urethra where it emerges from the beak of the prostate. This technic is advantageous both for impermeable stricture and for traumatic rupture of the urethra. Eight cuts show the various steps of the intervention, which commences like that of a perineal prostatectomy. When the prostate has been located the urethra is incised just below it, and a sound is introduced down to the stricture. The urethra can then be readily incised over this sound and another inserted from the external meatus as far as the stricture. The stricture tissue between the two sounds can then be readily excised.

35. **Handles for Surgical Pans, Etc.**—Jayle thinks that a handle would prevent the practice of putting the thumb on the inside of the edge in handling dishes.

38 (XXIII, No. 42.) *La néphrite toxique appendiculaire; albuminurie appendiculaire. Dieulafoy.
39 *Comparative Importance of Heart Disease as Cause of Dismissal from French and German Armies.—Sur l'importance comparée des maladies de coeur comme cause de réforme dans les armées française et allemande.
40 Letter from America. F. Munch.—Sur le climat des Etats-Unis.

38. **Appendicitic Nephritis and Albuminuria.**—Dieulafoy reveals another instance of the insidious treachery of the toxins generated in appendicitis by pointing out their action on the kidneys. The poison injures these organs surreptitiously, without calling attention to its work, and the only external evidence of it is albuminuria. Since he has been studying this phase of appendicitis he has found that every appendicitis of any severity has been accompanied by albuminuria, with or without casts. It appears the second or third day and may be accompanied by a subicteric complexion. The albumin may amount to as much as .25, .5 or 1 gm. or more; in several cases he has witnessed the gradual subsidence of the albuminuria after the appendix has been removed. In these

cases the kidneys have only been lightly touched by the toxins, but in others the lesions are fatally serious. In one case the kidneys, as usual, appeared sound to the eye, but the microscope revealed "nécrose de coagulation" and granular fragmentation of the epithelial protoplasm. This patient had succumbed the fourth day of a toxic appendicitis. In another similar case lesions of necrosis and degeneracy were restricted to the secretory apparatus of the kidney. These and similar cases known to Dieulafoy indicate that death was due to a profound intoxication of the organism rather than to the infection *per se*. The noble elements of the kidney are evidently affected by the cytotoxin generated in appendicitis, and the cells of the liver and stomach are liable to share the same fate. During the fatal cases above mentioned the temperature never rose above 100.4 F., and the pulse did not betray the severity of the intoxication. He thinks that the knowledge of the frequency with which the kidneys are damaged even in the earliest stages of appendicitis will impel the profession to operate early and not wait for the attack to subside. It is very probable that these appendicular toxins generated in acute and chronic appendicitis may be responsible to a certain extent for the development later of chronic nephritis and Bright's disease. Also for pathologic conditions in the liver, especially for cirrhosis of intestinal origin.

39. Heart Disease Among the Soldiers in France and Germany.—The Journal has referred more than once to the concern expressed by the German authorities in regard to the fact that the number of cases of heart disease among the men in the military service has more than doubled during the last twenty years. The proportion has risen from 1.5 to 3.1 per 1,000. In France there has been an increase, but not to the same extent, merely from 1.84 to 2.92 per 1,000. In Germany the number of recruits rejected on account of heart disease has risen from 9.9 per 1,000 in 1894 to 17.4 in 1898. In France these figures for the same years ranged only from 3.97 per 1,000 to 4.07. The editorial we are reviewing suggests as a possible explanation of the condition in Germany that the extensive emigration has drained away the most vigorous young men, and also that the reduction of the period of military service has possibly contributed, as the work of three years is now crowded into two.

45 *Ueber Anatomie und Pathologie der Placenta. Syncytium in dem schwangeren Uterus. Wirkung der Herz- und Nieren-Krankheiten auf die Muskulatur und Placenta. Atonie des Uterus. Placenta-Adhäreuz. Uterus ruptur. P. Kworostansky (Zurich).
46 Fall von chorio-villöser Neubildung (neoformation). M. Zondek.

42. Rupture of the Symphysis.—Kayser's patient was a young woman with normal pelvis and living child, extracted with forceps. The diastasis of the ends of the symphysis was 3 cm. at least. He sutured them together with silver wire, suturing the torn ligaments with catgut, draining and immobilization in a plaster cast. The patient recovered without any impairment of her gait or other disturbance. He advocates this procedure in all cases in which the extent of the gap, 2.5 cm. and more, renders the laceration of the ligaments probable. As the symphysis has such remarkable absorbing power, stagnation of even an aseptic secretion is liable to cause fever in these cases.

43. Hereditary Genital Tuberculosis.—Gottschalk regards the case he describes as one demonstrating the possibility of hereditary, primary genital tuberculosis. The uterus and adnexa were affected with tuberculosis and were removed by the vagina. The patient was a virgo intacta, with a tuberculous father. No other foci can be clinically detected and the patient has been permanently cured by removal of the diseased organs. Tubercle bacilli were found in the uterus, tubes and ovaries, but to date, three years since, not a trace of tuberculosis elsewhere can be discovered.

45. Anatomy and Pathology of the Placenta.—Microscopic study of 22 gravid uteri and of 6 morbid placentæ showed that the placenta has a remarkable capacity for adapting itself to its location and conditions of nutrition, etc. The mode of nidation of the ovum also varies according to the structure of the mucosa. The article is profusely illustrated.

47. Vincent's Angina.—This disorder, which has been recognized since 1893, is described by Hess, who distinguishes two types: 1. The rarer, croupous form with pseudo-membrane without great loss in substance, containing only the fusiform bacillus of Vincent and running a mild course. The membrane soon separates, leaving a very superficial ulcer succeeded by a second, thinner membrane, which after a few days also disappears. There is only a moderate fever for two or three days and slight swelling of the submaxillary glands. In the commoner, ulcerative diphtheria form, there is present, besides the bacillus, the Spirochaetis denticola. Pseudo-membrane forms in from two to four days with moderately deep ulcerations. The exudate is soft, gray, yellowish gray or greenish, and on removal reveals a bleeding ulcer with slight infiltration of the margins and the surrounding mucosa dark red and edematous. This is accompanied by considerable difficulty in swallowing, salivation and bad breath. The other tonsil may also be affected. The temperature goes up to 38 or 39 C. and there is a decided swelling of the neck glands, stiffness of the limbs, loss of appetite and a bad taste in the mouth. The disturbance in the general condition is usually only moderate, but may be severe. From the eighth to the tenth day the membrane separates, the ulcer heals up and very quick improvement occurs. Some cases of longer duration have been reported, from one to two months, and some defect may be left; in one case loss of the uvula has been recorded. The bacillus fusiformis differs from that of diphtheria in its length (6 to 12 microns), and in its form. It is thin and pointed at the ends and swollen in the middle, and lies scattered around like a diplobacillus, in radiating bundles, or the bacilli form acute angles. Its involution form shows vacuoles and other degenerative phenomena, and it forms no spores. It is readily stained with fuchsin and methylene blue and is markedly motile with long thin flagellæ, which appear at the ends and on both sides. The motility ceases in twenty minutes (Graupner). The bacilli are most numerous in the first days of the disease, and later, especially in the second form, other bacteria appear also. Pure cultures have never been obtained, the bacilli always occur with other bacteria. Spirillæ are present only in the second type of the disease. They are thin and long, twice as long as the bacillus, stain less readily and are not decolorized by the Gram stain; are very motile and likewise not cultivatable. They are found more abundantly on the surface than in the depths of the membrane. Inoculation experiments with the membrane or mucous membranes of sound animals have been generally without results, and the bacilli could be grown only in weak and tuberculous animals,

producing ulceration. Both microbes are saprophytes in the oral cavity and digestive tract. The spirillæ are never pathogenic except in combination with the fusiform bacillus. Seitz found the latter present in 110 out of 202 different disorders. The diagnosis of the condition is made positive by the presence of these forms and the non-presence of the true diphtheria bacillus, the exclusion of syphilis and the finding of staphylococci and streptococci only in the upper layer of the membrane. The therapeutics consists of gargles with chlorate of potash, etc., penciling with Lugol's solution, iodovasogen 5 per cent., silver nitrate, Peru balsam or methylene blue.

49. **Influenza and Appendicitis.**—Schultes has recognized 5 cases of appendicitis occurring in the course of influenza and attributable to influenzal infection which he reports. He reviews the literature of the subject to some extent.

50. **Tuberculosis of the Pharynx in Children.**—The rarity of this condition in children is first noticed by Schoetz, who reports 2 cases and notices those reported by Siegert, Catti and Comba. Altogether there have been reported 19 cases, a very small number considering the frequency of the condition in adults. He thinks it probable that in some instances it has been overlooked from its resemblance to diphtheria, which was diagnosed in one of his cases. The course is always fatal.

52. **Combined Method of Extirpating High Carcinoma in Rectum, Etc.**—In 4 cases Sasse has removed a carcinoma involving the higher portion of the rectum or colon. His first patient was a man of 45, and it is the first operation on record in which part of the rectum and small intestine were successfully removed in this way from a male subject. The other operations were on two elderly women and one man—the latter succumbing in a few days to peritonitis from an unsuspected hernia. The others are all in good health. Sasse commences the extirpation of the neoplasm by way of the perineum, sacrum or vagina, terminating it by a laparotomy, or vice versa, or returning from the second route to the first. He prefers the abdomino-sacral route for carcinoma reaching down to the floor of the Douglas or lower, with probable involvement of the lateral lymphatics. The statistics of this combined method show 20 recoveries in 35 operations, the mortality being 43 per cent., but by sex, the statistics show 93.3 per cent. recoveries in 13 women and 43 per cent. in 14 men. He describes his own material in detail. In the case first mentioned he commenced by resecting the sacrum, but found a loop of small intestine adherent with a communication into the rectum. He then tamponed this wound, raised the pelvis and proceeded to a median laparotomy. The loop of small intestine was resected and reunited with a Murphy button, and as much as possible of the mesocolon and pararectal connective tissue was dissected out and pushed out through the sacral opening. The peritoneum had been incised and turned back on each side of the field, and it was now sutured with catgut to leave no secreting surfaces in the abdominal cavity. The mesentery of the flexure was then mobilized and the small pelvis packed with a long strip of iodoform gauze, the end protruding from the sacral incision. The abdominal incision was then closed and the tumor then ablated *en masse*. The mucosa of the portion of the rectum left was removed at the same time and the upper stump drawn through it and sutured to the external anus. The temperature reached 38 C. only once. The intestine became gangrenous for 8 to 10 cm., resulting in the formation of a sacral anus, which healed in less than nine weeks. The patient was a farmer of 45, and he is in good health almost three years since, has gained in weight and has been a father. The first symptoms of the rectal cancer were noted two years before the operation.

55. **Histology of Gastric Mucosa.**—Einhorn gives in 15 cuts the microscopic aspect of sections of the stomach mucosa as selected from 34 cases of various stomach affections. He is convinced that the disorders in the secretory function are not due to primary alterations in the stomach mucosa, but that they entail the latter in time if long continued. He has been able in a few cases to diagnose cancer from a scrap of the mucosa, showing a direct proliferation of the cells of the epithelium into the gland substance. In regard to treatment of deranged secretory function, he thinks that the main stress should be laid on improvement of the general condition.

59. **Wattenlaufen—A New Therapeutic Sport.**—During the last few years a seacoast resort in northwest Germany has inaugurated a sport which is commended by Stelzner for its therapeutic value. With legs bare to the knee the people, young and old, men and women, flock to the shore as the tide goes out and promenade on the wet sand left bare by the receding tide. Many elderly persons come to this resort from a distance to take advantage of this sport as a therapeutic measure, saying that it ensures them a healthy winter. It is not practiced as a fad, but in all seriousness, and the return of the tide prevents excess. Stelzner reviews the indications and contraindications for this beach strolling, and states that its best effects are obtained in nervous affections, insomnia, etc., far surpassing those resulting from sea bathing.

63 *Tumors of Spinal Membrane. F. Schultz (Bonn).—Zur Diagnostik und operative Behandlung der Rückenmarkshautgeschwülste.

60. **Surgery of Pancreas.**—Mikulicz refers appreciatively to the recent work on this subject by Mayo Robson and Moynihan which has appeared since he delivered this address at Washington last May. (See page 1524 of last volume.) He advocates laparotomy when symptoms point to injury of the pancreas, although none of them is pathognomonic. After arresting the hemorrhage and rinsing out the peritoneal cavity with a 9 per cent. saline solution, he always applies tampon drainage even if he has been able to suture the wound in the pancreas. In acute pancreatitis he operates at once in order to put an end to the dangerous toxic-septic condition and prevent necrotic degeneration of the tissue of the gland from the abnormal pancreatic ferment. It is difficult to distinguish between acute pancreatitis and the so-called pancreas apoplexy, and chronic pancreatitis may simulate carcinoma of the organ. Chronic pancreatitis is induced by gallstones more frequently than by true pancreas stones. He has collected 75 cases of acute pancreatitis treated by surgical intervention. In 37 the pancreas itself was operated on, and 25 were cured. In 41 the pancreas was not operated on and only 4 of the patients recovered. He has operated on the pancreas thirty-one times. In 10 cases on account of cyst, including 2 ablations of the organ and 8 in which it was merely incised and drained. All the patients recovered. In 16 cases the intervention was for malignant tumors. He reviews his experiences in detail.

61. **Hypersecretion of Gastric Juice.**—Strauss describes the clinical picture of this condition, free from complications, as the finding of more than 30 c.c. of true gastric secretion in the empty stomach without sprouting sarcinæ and molds, and negative results to the fermentation and currant tests, indicating the lack of pronounced derangement of the motor function. From 10 to 20 c.c. indicates some abnormal condition; 20 to 30 is pathologic. The smallest amount he found in any case with clinical manifestations was 40 c.c. The acute and intermittent cases are generally of nervous origin, occurring in the course of tabes or severe functional neuroses, but sometimes they are due to some local condition of irritation, possibly from stenosis. The chronic form of gastrosuccorrhea may likewise be regarded as the result of some local irritation of the secreting apparatus of the stomach. This condition of irritation may be of intragastric origin, possibly from some motor disturbance, but usually outlasting the latter. Sometimes it is the result of gastric ulcer, which in turn is unfavorably influenced by the hypersecretion. In other cases the source of the irritation may lie outside the

stomach, and be neurogenic or hematogenic. He advocates in treatment systematic evacuation of the stomach content with the stomach tube. In case of motor derangement he supplements this by lavage, raising the pelvis. An albumin and fat diet is kept up for several weeks—butter and oils, with small, frequent meals, rectal feeding and, if necessary, a course of treatment as for gastric ulcer. For medication he prefers alkalies, with silver nitrate if needed, bismuth and atropin if there are paroxysms. Gastroenterostomy is the last resort. He concludes his article with a study of the metabolism in cases of hypersecretion.

62. **Subcutaneous Ruptures of Gastrointestinal Tract.**—Sauerbruch has made an exhaustive study of the conditions that produce contusions, rupture and laceration of the stomach and intestines. Contusions of the intestine may not be perceptible from the aspect of the viscus alone. They are liable to be induced by contusion of the spine or pelvis, the intestine almost empty and the force applied to a circumscribed region. A predisposition to rupture is afforded when the intestines are full or the loop of intestine closed at both ends with contusion of the abdomen affecting the distended loop. Laceration from traction is liable when the force is applied obliquely from below upward at an angle to the spine. Also when the contusion or traction affects an intestinal loop immovably fastened by physiologic or morbid conditions. These three types of injury may be associated. Further predisposition is afforded by reflex rigidity of the abdominal wall, muscular tonus, the condition of the peritoneum, shape of the pelvis and condition of the abdominal organs at the time, as in pregnancy, affections of the intestinal walls, etc.

63. **Tumors of Spinal Membrane.**—Schultze diagnoses a tumor in the spinal membrane in cases presenting a permanent and gradually progressing motor and sensory paralysis, its limits above always persisting at or near the same point, even in the absence of pain of any kind. These symptoms differentiate a tumor of the spine outside of the spinal cord after exclusion of syphilis, myelitis and vertebral affections. It may be difficult to differentiate the condition from multiple sclerosis, which may develop with the clinical picture of a transverse myelitis, and also from chronic pachymeningitis and leptomeningitis, intramedullary tumor and vertebral caries. In locating the tumor it is important to note besides the pain on pressure, the zones of exaggerated or deficient sensation and symptoms of motor derangement. The reflexes, pains and paresthesia at remote points are less important for the differentiation. He reports 10 cases, in 9 of which his diagnosis of an extramedullary tumor was confirmed by the operation or necropsy. Three of the patients were permanently cured by surgical intervention and one permanently improved, while 3 died soon afterward. A tumor of this kind is usually a fibroma or fibrosarcoma when it develops slowly and symptoms are observed for years. There was no evidence of trauma in his cases.

73 *Improved Electric Light for Examining. V. Pick.—Eine einfache Vorrichtung zur Verbesserung der elektrischen Untersuchungslampe.
74 The Lighting of Schools, etc. Report of Committee.—Die Beleuchtungsanlagen in den Erziehungs und Unterrichtsanstalten.

64. **Mirror Sphygmograph.**—Frank thinks that the weight of the parts of the sphygmographs in use prevents accurate measurement of the actual pulse wave. To obviate this inconvenience he has devised an apparatus in which the movements of the lever applied to the artery are reflected on a mirror constantly turning on its axis. Light is focused on the mirror in such a way that it follows the movements of the sphygmograph lever, and these variations are mirrored on a sheet of sensitized kodak film, likewise revolving on a roller with the same velocity as the mirror. In this way the pulse curve is recorded without interference from the weight of the parts of the registering apparatus. He uses a Nernst incandescent lamp for the source of the light, focused by a lens. The entire apparatus is small and simple and does not require particular skill on the part of the user.

67. **Axial Torsion of Large Intestine During Childbirth.**—Fromme has observed a case of this kind and has found 2 others in the literature, all befalling healthy young women at the onset of parturition. Each case terminated fatally. None was diagnosed correctly.

70. **Laughing-Gas Mixed Narcosis.**—Krönig gives cuts of an apparatus he has devised for this method of narcosis. It is a combination of Bennet's inhaler with the Braun apparatus. He has used it in 500 narcoses and proclaims that it is entirely free from the inconveniences of the initial stages of the usual chloroform and ether narcosis. He applies the mask with only air passing through it, and this tranquilizes the patient. He then turns on the odorless, compressed laughing-gas and in 40 to 60 seconds the patient is unconscious; ether can be substituted for the gas without his knowledge, and the narcosis proceeds smoothly.

71. **Vulpius' New Splints.**—The splints are made of aluminum and consist of a row of cross strips, each provided with a ring on the outside through which a rod of aluminum is slipped to hold them all firm. He gives illustrations of the mode of application and extols their superiority over other splints.

73. **Improved Electric Lamp for Examinations.**—Pick coats the bulb of an ordinary 16 candle-power incandescent lamp with a layer of gypsum, leaving only a small space free on one side. This concentrates the light at one point and leaves the rest of the room dark. He states that it is surprising how powerful a ray can be thus produced from an ordinary incandescent bulb.

84. **Classification of Lymphomatoses.**—Türk groups cases of lymphomatosis as the chronic benign, the acute and the chronic malignant. The first two groups are subdivided into the alymphemic, the sublymphemic and the lymphemic, the latter being chronic or acute lymphoid leukemia, both of benign character. The sublymphemic chronic benign is Pinkus' pseudolymphemia, and all forms of the partially aggressive, acute cases of lymphomatosis come under the heading of chloroma. The chronic malignant is lymphosarcomatosis, either local or generalized. All these types may appear independently and transitional forms may be observed, especially between the sublymphemic and lymphemic types. He describes a number of unpublished cases to illustrate the bases for this classification. He shows that chloroma is an acute lymphomatosis with a green coloring of the lymphoid proliferations and a special predilection in the skeleton for the periosteum and marrow in its localizations. The green coloring is an unessential symptom, not creating any essential difference between this form of the affection and other acute lymphomatoses of the same nature. Its predilection for the periosteum, dura and serosæ justifies the assumption of partial aggressiveness, and this is sustained by the findings in the spleen, glands and marrow which present regularly the anatomic characteristics of acute leukemia. That is to say, the points where the conditions are unfavorable for the washing away of the cells exhibit evidences of injury. When the lymphatic system is abnormally functioning or enlarging or the lymph cells are being produced in abnormal abundance—if the lymph cells are not swept away they pile up and cause the formation of a tumor. This is liable to become aggressive at any moment, and especially at those points where the local anatomic conditions are such as to interfere with the washing away of the cells. As these anatomic conditions differ at various points, the subject may exhibit simultaneously benign tumor formation at one place and partially aggressive at another, without justifying the assumption that two different processes are involved. Benign lymphomatosis is also liable to become transformed into a localized lymphosarcoma at any time. This is particularly likely to happen in the aleukemic forms, anything causing even a slight, local or transient increase of the slow, gradual proliferation may impart the impulse to local aggressive growth. In conclusion he notes that the more acute the course of the lymphomatosis the more pronounced the abnormal character of the cells. It is possible that the leucoblastic myeloid tissue may suffer likewise from such acute hyperplastic affections, with production of similarly abnormal cells, ending finally in cells which no longer differ essentially from those observed in acute lymphomatosis. There are probably borderland affections of these great systems, the intermediate rôle being the acute hyperplasia of both systems. It is possible that many puzzling cases may prove to be a myeloid counterpart to the acute lymphomatoses.

88. **Suture of the Septum in Prolapse Operations.**—This article was contributed to the Chrobak *Festschrift*, 1903, and is accompanied by ten cuts showing the various steps of the technic, the aim sought and the conditions realized. Gersuny believes that prolapse after childbirth is due more to the injury to the pelvic cellular tissue than to the stretching of the vagina, etc. He remedies the conditions in vaginal cystocele by restoring and strengthening the vesico-vaginal and the recto-vaginal septa. He detaches the anterior wall of the vagina from the cystocele throughout its entire extent. The wall of the bladder is then pushed inward and the size of the organ thus reduced, and this reduction assured by two sutures. This reduces or closes the gap in the septum, and by reuniting the anterior vaginal-wall flaps the suture of the septum is re-enforced. The proctocele is then treated in the same manner—a superficial circular suture is run around the prolapsed portion and after reduction the thread is drawn up and tied. The perineum is then restored with buried sutures, but the suture of the septa is the main feature of the intervention.

90. **Urotropin as Prophylactic Against Scarlet-Fever Nephritis.**—Widowitz has never had a case of nephritis among his 102 scarlet fever patients since he introduced the plan of preventive administration of urotropin. He gives from .05 gm. to .5 gm. of urotropin three times a day, according to age, during the first three days of the disease, and again at the beginning of the third week, for another three days.

91. **Circulus Vitiosus After Gastroenterostomy.**—Föderl reviews his experience as assistant at Gussenbauer's clinic, 1895-1902, during which time 62 gastroenterostomies were performed. A certain number presented symptoms of the circulus vitiosus, and Föderl is inclined to attribute this to the too acute angle formed by the anastomosed loop. As it bends in a sharp angle the lower wall projects into the lumen in a sharp fold, acting like a valve at times, closing the lumen of one or the other arm of the loop. He shows that this can be prevented by shortening the mesentery of the anastomosed loop. When three radial stitches have been taken in the mesentery just below the point of the anastomosis, and tied, this takes a tuck in the mesentery and the loop is unable to stretch up into a sharp point, but must retain its broad curve.

92. **Treatment of Gastric Ulcer.**—Lorenz relates two cases of the so-called callous penetrating gastric ulcer which required an operation. The patients were women of 52 and 57, and the tumors tore in each case as a drain tube was being introduced. This variety of ulcer does not have as good prognosis as others, but both these patients rapidly recovered. Lorenz thinks that there may possibly be some connection between this unexpectedly favorable result and the tearing of the ulcer tissue during the intervention. It may have mobilized the tissues and thus have created better conditions for healing in place of the rigid ulcer growth.

93. **Scopolamin-Morphin Narcosis.**—Stolz was obliged to complete the narcosis with inhalation of an anesthetic in 309 out of 465 patients anesthetized by the scopolamin-morphin method. Three of the patients died in consequence of the injections, one exhibited profound and 9 slight asphyxia, while heart weakness was frequently observed.

100 *Influence of Nutritive Enemata on Peristalsis and Secretion in Gastrointestinal Canal. O. Loewe (von Leube's clinic, Würzburg).—Ueber den Einfluss von Nährklystieren auf die Peristaltik und Sekretion im Magendarmkanal.

94. **Nitrogenous Substances in Pathologic Urine.**—The extensive researches here described may be epitomized in the statement that in diabetes, typhoid fever, liver affections and certain cases of exophthalmic goiter, there is a very slight in-

crease in the amido-acid nitrogen. Also that 1.5 to 3 per cent. of the total nitrogen in the urine consists of amido-acid nitrogen, and that this percentage may be increased by the diet. Von Jaksch announces further that 95.85 to 98.36 per cent. of the nitrogen in the urine in morbid conditions, not precipitated by phospho-tungstic acid, consists of urea. On the other hand, 5.16 to 8.51 per cent. of the nitrogenous compounds precipitated by this agent consists of purin bodies and ammonia. He found that 83.83 to 91.07 per cent. of the total nitrogen in the urine is in the form of urea, while 1.52 to 3.61 per cent. is in the form of amido-acid nitrogen. Multiplying the total nitrogen by the proportion of nitrogenous substances precipitated by phospho-tungstic acid in urine free from albumin, gives the percentage of urea sufficiently accurately enough for clinical purposes.

96. **Behavior of Tendon Reflexes in Kidney Disease.**—Lion found that the knee-jerk was about normal in afebrile cases of nephritis, but that it became exaggerated as the affection grew more serious, especially with threatening uremia. In contracted kidney with good diuresis it was normal. In only 5 out of 262 cases were the reflexes diminished. The exaggeration in severe nephritis may be regarded as a sign of retention of substances which normally enter into the formation of urine. As the symptoms become attenuated with recovery or transition into the chronic form the reflexes have a tendency to return to normal.

99. **Blood Pressure and Physical Exercise.**—Karrenstein refers to a vasodilating reflex the reduction of the blood pressure noted after long-continued physical exercise.

100. **Nutritive Enemata in Regard to Peristalsis.**—Loewe examined the exposed stomach and intestines of cats, after injection of a nutritive enema to the ileocecal valve. He found that the addition of opium rendered the absorption of the fluid possible without any motor stimulation of the stomach or small intestine. The large intestine always showed signs of peristalsis, although very slight, and it was noted also in the small intestine when the opium had been omitted. He concludes that nutritive enemata may be used with impunity in case of affections of the stomach and upper intestine, and (with opium) of the middle intestine, but they are contraindicated in case of perityphlitis and typhoid fever, especially during the period when the scabs are being thrown off. He found droplets of oil from the enema in the entire intestinal canal and even in the stomach in 2 cases.

104. **Electric Treatment of Aneurisms.**—De Freitas calls this method of positive cutaneous galvanism "the Brazilian method," and claims that it deserves the preference over all others, as it aids Nature, and is the easiest for the patient. He exhibited a patient at the local medical society whose aneurism of the ascending aorta had been reduced from 42 cm. in circumference to 37, with the complete cessation of all the annoying symptoms and final reduction of the aneurism by 5 cm. in all its diameters. In one patient, after potassium iodid had been used for two years without relief, the electric treatment proved rapidly successful in arresting the pains and distress. Another patient had been treated for five years in vain with other measures, and received the same benefit as the first from the electricity. His record includes 5 others all materially improved. As many as 50 sittings were needed in some cases to produce the desired result.

105. **Non-Transmission of Yellow Fever by Clothing.**—The committee appointed by the Brazilian authorities report an interesting series of experiments. Nine persons went to the isolation hospital and slept on bedding and wore garments from yellow fever patients. In the room occupied by some of the subjects three bottles were opened—one containing urine from a yellow fever patient, another black vomit, and a third some yellow fever feces. The garments and bedding were also shaken in the room. The tests were continued from February 18 to May, and none of the subjects nor the members of the committee have shown the slightest symptoms of illness to date.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

CLINICAL PATHOLOGY OF THE BLOOD. A Treatise on the General Principles and Applications of Hematology. By James Ewing, M.D., Professor of Pathology, Cornell University Medical College. New York. Second edition, revised and enlarged. Price, $3.50 net. Cloth. Pp. 492, with 43 engravings and 18 full-page colored plates. Philadelphia and New York: Lea Brothers & Co.

THE TREATMENT OF CERTAIN MALIGNANT GROWTHS BY EXCISION OF EXTERNAL CAROTIDS. By Robert H. M. Dawbarn, M.D., Professor of Surgery and Surgical Anatomy in the New York Polyclinic Medical School and Hospital. (The Samuel D. Gross Prize Essay.) Pp. xiii-192. Cloth. Price, $2.00 net. Philadelphia: F. A. Davis Company.

THE NATURE OF MAN. Studies in Optimistic Philosophy. By Elie Metchnikoff, Professor at the Pasteur Institute. The English Translation. Edited by P. Chalmers Mitchell, M.A., D.Sc., Oxon., Secretary of the Zoological Society of London. Cloth. Pp. 309. Price, $2.00 net. New York and London: G. P. Putnam's Sons. 1903.

A TEXT-BOOK OF PRACTICAL GYNECOLOGY, for Practitioners and Students. By D. Tod Gilliam, M.D., Professor of Gynecology in Starling Medical College, Columbus, Ohio. Cloth. Price, $4.00 net. OPERATIVE TREATMENT OF BILATERAL CICATRICIAL ANKYLOSIS OF THE JAWS.

A CONTRIBUTION BASED ON A REPORT OF A CASE OF TWENTY YEARS' DURATION, RELIEVED BY A SERIES OF PLASTIC AND OSTEOPLASTIC OPERATIONS.*

RUDOLPH MATAS, M.D.

NEW ORLEANS.

The occurrence of permanent trismus or "locked jaws" ("ankylosis," "occlusion," "constriction" of the jaws) may result from a variety of well-known causes which, according to the permanent or temporary nature of the cause, or the parts involved in the pathologic process, vary in their prognosis and in their amenability to treatment. It is not my purpose to discuss this subject systematically, but to limit my remarks to the consideration of that most frequent, distressing and intractable variety of trismus in which the jaws are permanently locked and immobilized by the formation of rigid cicatricial bands and masses which hold the maxillæ in an unyielding clasp, reduce the capacity of the buccal space and thus more or less completely interfere with the movements of mastication. (Ankylosis spuria mandibulæ of the older writers.)

While the movements of the lower jaw may be restricted by the formation of cicatrices in the soft parts outside of the mouth in consequence of destructive lesions, accidental injuries, pathologic processes and surgical operations which cause great destruction and scarring about the face, the peribuccal and perimaxillary tissues, as is often seen as a sequel of burns, gunshot wounds, carbuncles and malignant ulcerations, etc., these are not, as a rule, so serious from the functional or surgical point of view as the class of cases in which the immobility of the jaws is caused by a destruction of the lining mucosa of the mouth. In these cases the mucous membrane is usually destroyed by progressive ulceration or gangrenous inflammations which, spreading on the inner surface of the cheek, give rise to either unilateral or bilateral ulcerations, which in healing leave large areas of dense, retractile, cicatricial tissue. Many of the most destructive, gangrenous and ulcerative infections of the mouth which are responsible for the loss of the oral mucosa occur in early life (noma, cancrum oris, scarlatina, diphtheria, mercurial stomatitis, syphilis, tuberculosis), and, as a result of the tender age of the patients, lead, when neglected, to a series of secondary changes, which influence most injuriously the entire development of the face, thus adding great disfigurement to a distressing interference with a most important function.

When cicatricial trismus occurs in early childhood the development of the lower jaw is greatly interfered with, and it remains rudimentary and infantile in size and shape. The chin is dwarfed, small and retracted, giving to the face an asymmetrical and ungraceful appearance (micrognathism), which is most striking when viewed in profile (the so-called "bird face"). The eruption of the permanent teeth is likewise interfered with; the molars make their appearance in vicious attitudes; more often they are deviated from a vertical to an oblique or horizontal axis and the grinding surfaces face the tongue instead of the teeth of the upper jaw. The front teeth of the upper jaw project beyond the lower set; the lower teeth are imperfectly developed, unhealthy and covered with thick, offensive salivary incrustations and food accumulations. The secretions of the mouth are usually malodorous from stagnation, and there is a perceptible dribbling of saliva when the angles of the mouth are involved in the contraction. In spite of the rigidity of the jaws, the reduced buccal space, and the inability to separate the teeth, and of their extremely defective mode of feeding, it is remarkable how well these patients adapt themselves to these conditions and succeed in keeping up a fair state of general nutrition. More often, however, these persons succeed in nourishing themselves because of the absence of teeth or irregularities in their development, which allow the food to be forced between the missing teeth or interdental spaces. The entire muscular apparatus of mastication undergoes atrophic changes from arrested development and disuse; in fact, the entire innervation and vascular supply of the inframaxillary portion of the face suffers from the same cause and retains an infantile form, markedly contrasting with the upper jaw and face, which continue to develop and grow in normal proportion until adult life.

To add to the complexity of these cases, we find that the cicatricial masses in the rear mouth undergo, in some instances, a process of osseous infiltration, which transforms the scar tissue into a solid piece of bone, of the consistence of old callus, which permanently unites the upper and lower maxillæ into a single immovable bone.[1] This is particularly true of those fortunately rare cases in which the original causal infection has spread from the mucosa to the periosteum, exciting this to the formation of hyperostoses by the proliferation of osteoblasts in the budding granulation tissue.

When these ossified bands exist, they are usually found in the posterior part of the mouth, in the vestibular

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

1. Numerous cases of ossification of intrabuccal bands will be found reported in the literature; the cases reported by C. Esterle, B. Holt, Marchiafava, Sebastian, Walter, Sarrazin, Heath, and others, are fully referred to in the index catalogue of the Surgeon-General's library, vol. vii.

space, extending from the upper gingival border to the inner surface of the body of the lower jaw, as far forward as the bicuspids or even the commissure of the mouth. In dealing with cicatricial occlusion within the mouth, the resistance, thickness and density of the scar bands must be considered. Not only is the cartilaginous and osseous transformation of these bands a matter of importance, but their situation and limitations are of still greater importance in determining the prognosis and the mode of procedure.

As shown by Verneuil, who so ably studied this form of maxillary ankylosis 40 years ago, we should try to distinguish, for practical purposes, the cases in which the cicatrices occupy the anterior from those which contract the posterior regions of the oral cavity. When the scar bands are limited to the anterior (facial) part of the vestibule and lips, the prospect of operative relief is excellent and the prognosis very favorable; but when the scar masses are formed on a level with the last molar or in the pterygoid region along the angle, body, and ramus, the possibility of restoring the mobility of the lower jaw without resorting to some form of intrabuccal plasty, combined with osteotomy and pseudarthrosis, is reduced to a minimum. Even a comparatively superficial destruction of the mucous membrane in the retrovestibular space and along the inner surface of the ramus is sufficient to cause permanent contraction and immobility of the jaw, because in the normal state the mucous membrane is tightly stretched over and adherent to the periosteum and peribuccal tissues. Inflammatory and ulcerative processes starting in the mucous membrane at this level, therefore, are easily propagated to the periosteum and bone, forming dense, fused, unyielding masses, which do not permit of anatomic differentiation into their component elements.

It is evident from what has been stated that the problem which confronts the surgeon who would attempt to give relief in such cases by mobilizing and liberating the lower jaw is far more complex than a superficial glance at the subject would imply. In fact, the division or excision of the constricting cicatricial bands is only one of its phases, and other factors in the problem must be considered before anything like a functional restitution of the lower jaw can be obtained. In view of the arrested development of the jaw, of the atrophied and shortened muscles and ligaments which are concerned in the control of the inferior maxilla, and the vicious attitude of the teeth, it is evident that neither a functional, cosmetic or anatomic restitution, in a complete sense, can be expected by any mode of treatment. Nevertheless, even in such extreme cases, fortunately very rare at the present time (when the opportunities for surgical relief are given to all in almost every community), the surgeon may still hope to restore the mobility of the lower jaw sufficiently to permit of easy feeding and mastication, and thus greatly relieve the condition of these unfortunate sufferers.

In the treatment of the rare and grave type of cases which we have in view, no single method of treatment will suffice, and it is only by judiciously combining a variety of procedures that we may hope to release the jaw and obtain a certain degree of mobility which will permit the patient to open his mouth and to masticate solid food.

In unilateral cases, and especially where the scar tissue only involves the angle of the mouth and lateral aspect of the cheek, the problem is solved with comparative ease, and a simple plastic operation will generally suffice. In the symmetrical or bilateral cases involving the deeper recesses of the oral cavity, osseous sections must be added to dermal transplantations to obtain the desired result. None of the ordinary methods by which the jaw can be forcibly separated by mechanical dilators, wedges, conical screws or mouth gags, can be expected to give even temporary relief; to have attempted any procedure of this sort on the patient whose history has furnished the text for this paper, would have resulted simply in breaking the teeth or fracturing the jaws. The simple division of the ossified cicatricial masses with knife and chisel would have been dangerous on account of the great depth of the scars, and could not be considered.

Mears' method of dividing the scar tissue after creating a mucous lined tunnel under it with a seton-like ligature, valuable as it is and worthy of trial in simpler cases, was evidently impossible here.[2]

The various procedures which have been recommended for the permanent relief of cicatricial occlusion of the jaws, exclusive of the simple palliative and mechanical methods previously referred to, may be grouped under the following heads:

1. Division and excision of the scar tissue with substitution of transplanted skin or of mucous flaps, for the lost mucosa.

2. Division and detachment of tendinous insertions and aponeurotic expansions of the muscles of mastication at their surface of attachment to the lower jaw (masseter, pterygoid, etc.), after division of the cicatricial bands in the mouth.

3. Creation of a new point or center of motion in the body of the jaw (pseudarthrosis) by osteotomy in front of the resisting and unyielding scar masses when these exist in the postbuccal space.

4. Excision of the temporomaxillary joint, condyle or part of the lower jaw, with or without associate myoplasty.

EXCISION OF SCAR AND SUBSTITUTION OF HEALTHY SKIN.

The first group embraces the greatest number of suggestions, some of these very ingenious. We should note that in recent years and since the advent of a more aggressive and radical technic for the cure of malignant diseases, the indications for the extirpation of the mucous membrane of the mouth in dealing with growths of the face, and especially of the cheeks and lips, have increased. Surgeons have been compelled to tax their ingenuity considerably in the effort to prevent the con-

2. Dr. Mears' method is thus described by the author ("The Operative Treatment of Occlusion of the Jaws," by J. Ewing Mears, THE JOURNAL A. M. A., Sept. 18, 1897): "In performing this operation a long-handled, slightly curved needle threaded with a strong aseptic twisted-silk ligature of sufficient length, is introduced at the angle of the mouth on the inner surface and carried carefully into the space between the cicatricial mass and the buccinator muscle and the point made to emerge at the posterior border of the last molar tooth of the lower jaw—at which point the posterior border of the cicatricial tissue can usually be felt. The ligature is now seized with the toothed forceps, the needle withdrawn, the ends tied and the ligature left loosely in the channel thus formed. As the intention is not to divide the mass by the ligature, this is permitted to remain without traction, the formation of the canal lined by normal mucous membrane being facilitated by drawing the ligature backward and forward, and thus destroying any adhesions which may form. When a probe passes readily and smoothly and without provoking bleeding, it may be assumed that the canal is lined by normal mucous membrane. This is usually accomplished in three weeks, when the scar tissue is divided with a blunt-pointed bistoury introduced into the canal." A mouth gag is then introduced between the teeth, and the mouth forced open to the widest extent. This is repeated at intervals until the mouth is healed, etc. Dr. Mears' experience with this method appears to have demonstrated its permanent value.

tractions that necessarily follow an extensive extirpation of the mucosa.

In the endeavor to find a suitable material, free from the retractile tendency of scar tissue, a number of plastic operations have been devised (cheiloplasty and meloplasty), in which the transplantation of pediculated skin flaps have figured largely. Autoplastic skin flaps obtained from all parts of the face, neck and cheek and upper extremities have been utilized; mucous flaps from the mouth (palate and lips) have been tried less often; Thiersch grafts have been utilized freely as secondary aids to epidermization of raw surfaces; even heteroplastic flaps taken from the mucous lining of the dog's mouth have been transplanted from the living animal, but with very doubtful results.[3]

Among the more practicable and useful of the numerous plastic operations that have been suggested is the meloplasty of Jäsche.[4] This operator, after splitting the cheek from the angle of the mouth to the masseter, including the cicatrized mucosa, sutured the skin of the cheek, on each side of the fissure, to the gums and mucosa of the vestibule inside of the mouth. After adhesion of the skin has taken place, two semilunar skin flaps of sufficient length are dissected out of the skin of the cheek and attached to the upper and lower lining of the artificial oral cleft, leaving the flaps attached to the gums, thus inverting the free skin edges into the mouth. After this the flaps are sutured in the mouth by their edges and the cheek is closed over the defect, restoring the mouth to its normal dimensions. Gussenbauer's[5] method is in some cases still more serviceable. This author, after splitting the cheek through and through, from mouth to masseter, and thus dividing all resisting scar tissue freely, cuts a trapezoidal flap out of the lateral aspect of the neck and folds it over the denuded masseter into the mouth where it is sutured to the mucosa. After adhesions have been contracted, the pedicle is cut off and the graft is turned into the mouth throughout its free extent, with its dermal surface facing the teeth. After suturing it in place to the edges of the cleft and angle of the mouth on the inner side, the cheek is closed. Jäsche's and Gussenbauer's operations are typical of the modern methods of autoplasty and differ from the earlier operations,[6] in which attempts at plastic repair were made by sliding flaps in which the dermal surface remained external and no allowance was made for secondary contraction of the flap surface on the inner or mucous side of the mouth.

Gersuny opens the mouth through an external incision made along the lower border of the jaw from the chin to the angle. A skin flap large enough to cover the defective area in the mouth is dissected from the submaxillary region and is completely mobilized, with the exception of a pedicle made of periosteum, cervical aponeurosis and other subcutaneous tissues. With this pedicle as a base of vascular supply, the flap is turned into the mouth with the skin surface facing the teeth and is attached to the free margins of the defect. The external incision is then closed. This method has been variously modified by v. Hacker, Eiselsberg, and Kraske. Its chief merit is that it diminishes the scarring in the face. On the other hand, Bardenheuer utilizes a pediculated flap borrowed from the hairless parts of the forehead with its pedicle attached to the lateral surface of the nose. This flap is turned into the mouth, where the skin is substituted for the defective mucosa. When the skin of the cheek has been destroyed with the mucous membrane, an additional pediculated flap is borrowed from the neck and made to cover the cheek in such a manner that the raw surfaces of both flaps are brought together; thus the forehead flap is made to serve as mucosa and the neck flap covers the defect in the cheek. This method has been adopted, with modifications, by Oberst, Rötter and others. In other cases, Bardenheuer filled the defects in the cheek with pediculated flaps borrowed from the arm.

Partsch of Breslau prepares his flap for transplantation before attempting to use it in the mouth by first dissecting and mobilizing it in the neck, after which its raw surface is covered with Thiersch grafts. In this manner the flap is covered with epidermis on both surfaces. When epidermization has been accomplished, the diseased area in the cheek is removed and the graft thus prepared is attached permanently *in situ*. In cases in which the gap to be covered in the mouth is very great, Hahn and Israel cut a very long pediculated flap from the neck and attach it to the mouth with the skin surface looking inward; after this has become adherent, the long pedicle is detached at its root and what remains of the flap is folded on itself so that the raw surfaces come together, leaving a thick double layer of skin at the seat of the defect. Hahn's flaps begin at the clavicle and end at the mamma. The flap is dissected upward toward its clavicular attachment and the mammary end is attached to the mouth; subsequently, when this has adhered, the clavicular pedicle is divided and the flap is folded on itself like a booklet, forming a double layer, as in the previous case. Following the same plan, Israel makes his flap extend from the angle of the jaw to the clavicle and utilizes them in the same way.

Czerny has applied similar methods by cutting out a long flap with its pedicle at the zygoma and its free extremity as low down as the middle of the sterno-mastoid; this flap is folded on itself and made to cover the defect in the cheek at the same sitting. In connection with these plastic transplantations of the skin into the mouth (meloplasty), it is well to remember with Lexar,[7] to whom I am indebted for a large number of the preceding references, that the hope once entertained that the skin when transplanted into the mouth would lose its cutaneous peculiarities and finally cease to grow hair, has never been realized, though it has been shown by Ritschl that the skin does undergo atrophic changes in the course of time. Tufts of hair will grow in the mouth years after the transplantation of the skin. Thiersch mentions a case in which hair formed in this way 21 years after the operation. Hence the importance of selecting skin from normally hairless surfaces whenever possible. In operations on the cheek, the preservation of Stenson's duct and its replantation into the mouth is very important to prevent "weeping" scars.

7. Handbuch der Praktischen Chirurg., Bergmann-Bruns-Mikulicz, Bd. 1.

In a few suitable cases the mucous membrane of the mouth in the vicinity of the excised areas may be utilized to cover the defect. We have already referred to Halsted's unique experience when he attempted to relieve cicatricial trismus by transplanting a fresh nonpediculated graft from the mouth of a dog to that of a boy suffering with this defect. I am not aware that the final outcome of this experiment has ever been published, but it is evidently an extremely uncertain method, which offers little prospects of practical results. In regard to the autogenic mucous grafts, Bayer has covered a defect in the cheeks by covering it with a mucous flap transplanted from the hard palate. In a case of carcinoma of the cheek, Oberst succeeded in overcoming the defect by cutting out two pediculated flaps from the inner (mucous) surface of the upper and lower lips respectively. He split the cheek to the masseter, extirpated the neoplasm and dissected the flaps from the upper and lower lips on their inner surfaces, sutured them together along their edges, leaving the raw surface outward, and the edges of the cheek-incision were closed over them. But these methods are of very limited application as compared with the cutaneous flaps, which are generally accessible and are far more manageable.

MYOTOMIES AND MYOPLASTIES.

In the second group of procedures that have been suggested and applied for the relief of cicatricial ankylosis, we should mention the division of the muscles of mastication or the detachment of their tendinous insertions with the object of creating more advantageous points of attachment and thus increasing the mobility of the lower jaw. It is doubtful that any permanent results can be obtained solely by myologic sections or reimplantations, except in cases of purely myopathic occlusion of the jaws. Such cases are reported in the literature in which good effects have been claimed, but the operations were either too recent when reported to prove the permanent success of the method adopted, or the procedures have been applied to cases in which the cicatricial contractions involved only the anterior region of the mouth and cheeks. In other instances the myotomies have been assisted by making a section of the jaw and creating a false joint, which is the really effective agent.

Gurdon Buck (1840), J. Carnochan (1846), J. R. Wood of New York (1850), J. W. Schmidt of Boston (1854), Müller and Little of New York, were among the first surgeons to report cases of tenotomy and division of the masseter and temporal for the relief of cicatricial constriction of the jaws in this country. The surgeons of other countries have reported a number of observations. LeDentu, in a more recent period, obtained a satisfactory result in a case in which the rigidity of the jaws was apparently caused by permanent contraction of the masseter and internal pterygoid, by making an incision along the angle of the jaw, through which he detached the masseter from its lower insertion as high up as possible; the adhesions of the mucosa to the body and ramus were also detached, and the internal pterygoid was also mobilized with a periostome. After these parts had been freely mobilized, he was able to open the mouth with a gag and kept the jaws wide apart for several weeks until the muscles had become permanently inserted at a higher point of attachment.

More frequently, sections of the muscles (masseter, temporal) have been made with the view of interposing muscular and aponeurotic flaps between the sections of the lower jaw, which is divided at the angle or at the ramus with the view of creating a false joint. In order to prevent the subsequent union of the fragments, muscular flaps borrowed from the masseter and pterygoids are interposed and sutured between the edges of the divided bone to insure the permanency of the pseudarthrosis. Verneuil first suggested this modification of Esmarch's operation and Helferich has adopted the same idea, in cases of true ankylosis of the temporomaxillary joint, by turning down a flap of the temporal after excision of the condyle. Lenz, Mikulicz, Riegner, Henle and Rochet have reported good results from this combined myo-osteoplasty.

OSSEOUS SECTIONS AND OSTEOPLASTIC OPERATIONS.

Sections of the lower jaw have been made through the condyle, the coronoid process, ramus and the body of the jaw. More frequently the temporomaxillary articulation has been excised or a linear section of the body (Rizzoli) or a cuneiform excision of the body (Esmarch) on a level with the angle, and including the angle, are now made, with the view of creating a pseudarthrosis.

Rhea Barton of Philadelphia was the first to suggest osteotomy for the relief of ankylosis in orthopedic surgery. Berard first suggested osteotomy of the condyle in ankylosis of the jaw. Carnochan, Richet, Dieffenbach took up the same idea and favored it about 1846. W. Grube[8] is credited as the first, according to Mathé (quoted by F. Guniyon[9]), to perform an osteotomy of the ramus for ankylosis of the jaws by intrabuccal section, in 1863.

A. Cabot of Boston and Koenig have clearly defined the indications for temporomaxillary excision. Baumgartner, Küster, Kraske and Bergmann have contributed modifications in the operative technic, which are more or less advantageous. Excision of the temporomaxillary joint is now restricted to cases of true ankylosis of this joint, and the myoplasties which have been suggested by Verneuil and others previously referred to, simply aim at the prevention of recurrence of the ankylosis by the new formation of bone tissue between the excised fragments. The most decisive step in the operative treatment of cicatricial constriction was not made until Esmarch and Rizzoli almost simultaneously and independently of each other suggested and performed, in 1854 and 1857, the operations which bear their names. The object of both operators was to create a false joint in the body of the lower jaw in front of the unyielding cicatricial bands. Esmarch removed a section of bone and Rizzoli made a linear osteotomy. The two procedures have been variously modified, but Esmarch's operation is the one generally preferred, as it is the most certain to prevent a reunion of the bone fragments. The modification first suggested by Bruns, Bonnet, Wagner and Heath, by which a triangular piece of bone is removed from the body of the jaw, including the angle, is the one now preferred. The operation is best performed by external incision and without opening the mouth (Levrat). The Gigli saw is particularly well adapted for this purpose. The external incision will also permit the masseter and external pterygoid to be detached from their insertions as a preliminary to the excision of the angle.

The immediate results of this operation are strikingly satisfactory in mobilizing the jaw; but in order to obtain the best results in long-standing cases, as in

8. Arch. f. Klin. Chir., Berlin, 1863, iv, 165-182.
9. Dict. Encycloped. des Science. Méd. (Déchambre).

the instance here reported, the cicatricial tissue in the mouth must be excised and a flap of skin, transplanted from the nearest hairless region into the mouth, must be substituted for the missing or contracted mucosa. In bilateral cicatricial cases involving the deeper regions of the oral cavity, a combination of methods is indicated.

The selection of the method in each case must be made judiciously, according to the special conditions existing in the case. It must be remembered, however, in making Esmarch's pseudarthrosis that a false joint should be made on one side only, and that nothing is gained by a bilateral section of the body of the jaw. This has been done by some surgeons, but it is evident that they have overlooked the fundamental fact that by the division of the jaw on both sides by osteotomy not only is the nutrition of the middle fragment greatly impaired, so that it becomes an easy prey to infection and necrotic changes, but that all control of the isolated middle piece and the capacity to chew food, and even to open the mouth and close it, voluntarily, is greatly impaired, because of the separation and isolation of the middle fragment from the muscles of mastication. It is, therefore, important, in all bilateral cases, to limit the formation of a false joint to one side only, so that the function of the masseter, pterygoid and temporal of the other side may be maintained. The removal of the anterior cicatricial bands and substitution of dermal flaps by autoplasty will usually suffice to give to the patient motion and control of the jaw. Should more motion be required, the excision of the condyle, part of the ramus of the jaw (without injuring the temporal and pterygoid) on the side opposite the pseudarthrosis, will give room for the play of the muscles of mastication by increasing the temporomaxillary space. This last expedient is, however, only justifiable in cicatricial ankylosis of the grave osteogenic type herein described.

GENERAL CONCLUSIONS.

In cicatricial constriction of the jaw, the operative treatment must be guided by a full knowledge of the seat of the constricting bands; their extent, their density and their association with secondary developmental defects or associate lesions in the osseous, articular and muscular apparatus of the lower jaw. The age of the patient, the cause of the lesion, duration of the trismic condition, the seat and extent of the cicatrices, whether extra- or intra-buccal, are the most important elements in determining the final results of the operative treatment.

2. The most intractable and difficult cases are those in which the lesions are symmetric and bilateral, which begin in inflammatory and necrogenic processes in the mucous membrane of the retrovestibular and pterygoid regions of the mouth in early childhood, and are neglected until atrophic, degenerative and developmental changes in the maxilla and its condyle have taken place.

3. The best results are obtained by early and persistent treatment.

4. In the complex and neglected cases of the class referred to (intrabuccal), no single operative method is sufficient to obtain permanent relief. The cases involving the anterior portion of the mouth and cheek are the most favorable for treatment, and the simple method of division of the cicatrices suggested by Mears will probably suffice. In the deeper or retrobuccal cases, a combination of methods, including autoplastic skin transplantations, osseous sections, with the creation of an unilateral pseudarthrosis (Esmarch), with or without myoplasty, will be required to obtain a moderate, but advantageous, degree of motion of the lower jaw.

5. Simple plastic operations to replace the lost mucous membrane by transplanting skin are necessary, but not sufficient in the deeper posterior bilateral cicatricial contractions. They must be regarded solely as adjuncts to the formation of a pseudarthrosis.

6. In making a false joint by Esmarch's or Rizzoli's method, it is important that the procedure should be limited to one side only, because a bilateral pseudarthrosis will result simply in increasing the mobility of the intervening fragment, with loss of voluntary control. The best results are obtained by unilateral pseudarthrosis, combined with bilateral plastic dermal transplantations, to which may be added, in the gravest cases, excision of the maxillary condyle on the side opposite the pseudarthrosis, without damaging the temporal, pterygoid or masseteric attachments.

7. By the combination of the methods above presented and a prolonged course of maxillary gymnastics following osteoplasty, functional results may be obtained, even in the most forbidding cases, without, however, the expectation of attaining the surgical ideal, either as to cosmetic or functional results.

CLINICAL OBSERVATION.

E. S., age 28, white, male, farmer, was admitted to the Charity Hospital Nov. 14, 1900. The patient is a native of Louisiana; single; of good habits and gives an excellent family history; father and mother both living and healthy; has four sisters and five brothers all living and well. Has never had gonorrhea or syphilis and has never been addicted to alcohol. When 7 years old he had a fever which was called "brain fever," and during the treatment was given calomel, which caused a violent stomatitis and salivation followed by deep ulceration on both sides of the mouth and especially the inner surfaces of both cheeks. It was two months before his mouth was well, and after healing he found that he was unable to open his jaws in consequence of the cicatricial contraction of the mucous membrane. When 17 years old he had malarial fever and he was treated with calomel with the result that he was again salivated, leaving ulcers in his mouth which healed in two weeks. After these had healed his mouth was more firmly closed than ever and he had great difficulty in feeding himself. When he was 25 years of age he was again sick with malarial fever, and was once more treated with calomel, which was followed by the usual salivation and an ulcerative stomatitis which lasted several days. Since that time the original contraction of the mouth which had completely immobilized his jaws had greatly altered his physiognomy and had compelled him to subsist purely on fluid and semifluid foods. In 1898 a physician made an incision over the left condyle of the lower jaw, probably with the intention of resecting the condyle, but there is no evidence to show that this was accomplished. Several efforts were made at various times to force his mouth open by mechanical means, but nothing was obtained by these efforts except to cause him to lose several of his teeth.

Jan. 15, 1901, he was again admitted to the Charity Hospital and examined for the first time by the writer. The general examination showed a healthy man, apparently fairly well nourished, about 5 feet 5 inches in height and weighing about 125 pounds. The face at once attracted attention by the small and undeveloped appearance of the chin and by the immobility of the lower jaw, which gave a fixed, rigid and set expression to the face. The angles of the mouth were drawn down and were adherent, especially on the left side, to the lower jaw by a distinct synechial band. The front teeth (incisors and canines) were irregular, notched, carious and incrusted with tartar. They projected for a considerable distance in a forward and oblique direction over those of the lower set, which were even more irregular, carious and stained

by calcareous deposits and tobacco juice. The gums were ulcerated and retracted from the teeth. A tendency to salivary dribbling was noticeable at the angles of the mouth. The chin receded and was small, contrasting with the upper half of the face, which was well developed; the hair of the beard, of a light sandy color, was scant and there was scarcely any growth of hair on the chin or lips. The cheeks were rounded and fully developed, contrasting in this way with the smallness and infantile appearance of the chin and lower jaw. The patient spoke without moving the jaws, and this gave his speech a peculiar and indistinct enunciation. The jaws were so firmly set that the point of a pocket penknife could scarcely be inserted flatwise between the front teeth. On attempting to explore the mouth with the fingers it was found that the entrance to the vestibule was blocked, on a level with the canines, by the existence of extensive cicatricial bands, which, beginning at the angles of the mouth, prevented further access to the space between the cheek and teeth on both sides. The back teeth and molars appeared to be in absolute contact. A probe could not be passed between the rows of the back teeth and only penetrated to the end of the vestibule by keeping it in close contact with the bicuspids and molars. Not the least impression could be made on the lower jaw by any manipulation. Evidently the inner surface of both cheeks was lined by a cicatricial mass, which had entirely replaced the normal mucosa. It was remarkable in this case, as in other reported instances, that the general nutrition had been maintained throughout the long period of twenty years that this condition had lasted, and that the patient had not suffered a great loss of body weight in spite of the notable interference with alimentation. This was partly accounted for by the fact that the patient had lost several of his teeth and had succeeded in feeding himself with milk, eggs, cereals, soups and other soft foods, such as chopped meats, which he crowded into his mouth with the help of his fingers.

In view of the extremely aggravated condition thus presented to us, the existence of a bilateral and extensive symmetrical constriction produced by cicatricial bands which had entirely replaced the mucosa of the vestibule and of the cheeks, and also of the atrophied, rudimentary and undeveloped state of the lower jaw and of the entire masticatory apparatus—we were undecided for a while as to the best course to pursue. It was plain that nothing could be accomplished by the usual mechanical methods of separating the jaws or of dividing the cicatrices by the simple intrabuccal methods recommended by some writers, more especially by Mears, as there was absolutely no room for any intra-oral manipulations. Nevertheless, after further deliberation I decided to divide the cicatricial masses on both sides by the procedure originally suggested by G. Jäsche, who described it nearly a half century ago, and which permits not only of a free visual exploration of the mouth, but also favors a substitution of the flexible skin of the cheek for the rigid and unyielding scar tissue after this has been divided and excised. This procedure appeared to be particularly applicable in his case, as the redundancy of the cheeks afforded an abundance of material for plastic work.

First Operation.—Feb. 1, 1901, the first stage of Jäsche's operation was undertaken. After a preliminary administration of one-quarter grain of morphin hypodermically, the cheeks were infiltrated along the line of the proposed incision from the angle of the mouth to the masseter, a little below the middle line of the cheek. The cutaneous incision was mapped out with an intradermal injection of one-fifth of 1 per cent. Schleich solution, and the subcutaneous tissue was made tense by massive infiltration of a 0.2 per cent. eucain B. isotonic saline solution injected with the author's infiltration apparatus. The dense tissues lying between the mucosa of the mouth, the ascending ramus of the jaw and the masseter were also infiltrated with the help of a long needle attached to the apparatus. An incision was then made which completely divided the cheek and opened the buccal cavity from the mouth to the anterior border of the ascending ramus of the lower jaw (Fig. 1). In doing this it was found that the mucous lining of the cheek had been completely replaced by a dense, thick scar tissue, which became harder as the ascending ramus of the jaw was approached. It was very difficult to divide this dense fibrous tissue with a knife, and as the end of the vestibular space was reached it was found necessary to resort to the sharp edge of a McEwen chisel to divide the scar tissue, which on the level with the last molars was found ossified and forming a bony bridge which clamped the two jaws and held them together as a single piece from one alveolar process to the other. By using the chisel freely the ossified tissue was divided and a considerable part of it was excised and removed. The cheek of the right side was anesthetized and treated in the same manner, the osseous bridge and scar tissue existing to the same extent as on the opposite side. After this had been done it was found the narrow space between the cheek and teeth was filled with a soft calculous mass formed by a mixture of tartar, stagnant food and precipitated tobacco juice, all of which had accumulated and formed a thick magma in this inaccessible space. After removing this stagnant mass on both sides we were able to explore the mouth and investigate the condition and relations of the teeth more satisfactorily. By insinuating the edge of the chisel behind the molars we divided all constricting bands and ossified masses to the ramus of the jaw, and by using the chisel as a lever we were soon able to pry open the jaw sufficiently to explore the interior of the mouth and determine the full extent of the constricting lesion. By further use of a

Fig. 1.—First stage of Jäsche's operation shown in profile. Incision from angle of mouth to anterior border of masseter.

conical dilator and by forcible manipulation with the hands we succeeded in separating the jaws 2½ inches apart, but we desisted from further efforts at this point for fear of breaking the delicate and undeveloped lower jaw.

After opening the mouth freely in this way we were at once struck by the vicious attitude of the permanent molars and bicuspids. In the twenty years that the constriction had existed the eruption of the permanent teeth had evidently been interfered with, and they had grown upward in an oblique direction, finally assuming a horizontal position so that the normal axis of each tooth was set at right angles to the alveolar margin; thus the grinding surfaces of the teeth were all turned toward the interior of the mouth. This abnormal attitude was much more marked in the lower than in the upper teeth. Having now obtained as much separation as was practically necessary for alimentation, we completed the first step of Jäsche's operation by suturing the cutaneous edges of the divided cheek flaps with the relics of mucosa and dense tissue which covered the upper and lower alveolar processes at the gingivobuccal junction. This was done with some difficulty, as the sutures would cut through the scar tissue whenever they were tied with even moderate tension. We therefore found it necessary to support the tissues by packing the large buccal clefts that we had created on each side of the mouth with strips of iodoform gauze and holding these in place with adhesive straps. Fortunately, on account of the abundance of skin covering the cheeks, there was no tension,

we had little difficulty in maintaining the flaps inverted into the mouth until healing had taken place.

In the course of a few weeks the skin of the cheeks had united with the gums throughout the whole line of incision, and the appearance of the patient was that of a man with a huge oral cleft or macrostoma which extended from one masseter to the other (Fig. 2). After healing had taken place systematic efforts were made to widen the interspace between the jaws with the view of stretching the contracted and shortened muscles of mastication and of increasing as much as possible the impaired mobility of the lower maxillary. For this purpose several contrivances were used. In addition to the usual mouth gags (conical and Goodwillie's) a special contrivance by which elastic traction could be made on the lower jaw with rubber tubing was found particularly beneficial. This most effective appliance was used as follows: A heavy piece of rubber tubing 3½ feet long by ½ inch in diameter was stretched over the mouth in the cleft as far back as possible, behind the last molar so as to fit like a bit in a horse's mouth; the free ends of the tube were then crossed as a figure of 8 back

Fig. 2.—Profile, showing result after first stage of Jäsche's operation; a macrostoma or oral cleft remains as an extension of the mouth on both sides, to the masseter; the skin edges of the cleft are attached to the gums and vestibule of the mouth.

of the neck and each end again carried down in front of the chest on each side, below each axilla, and tied over the back of the chest while the rubber was stretched (Fig. 3). The immediate effect of this was to cause a flexure of the head on the neck and chest, but by forcibly extending the head backward while the patient was in a horizontal position the elastic tension made on the lower jaw caused the mouth to open to the widest possible extent compatible with the resistance of the muscles of mastication. By persisting in the fullest extended attitude of the head all muscular resistance was gradually overcome and even ligamentous tissues yielded and the maximum amount of separation of the jaws was obtained with the least amount of traumatism or suffering to the patient. Whenever the patient would tire of the extension he would simply flex the head and the elastic tension would at once diminish sufficiently to give relief. In this way elastic extension could be kept up intermittently for periods of half an hour or more at a time, thus securing the benefits of prolonged treatment, which he learned to apply himself with decided advantage.

The patient gave us the benefit of his most conscientious cooperation throughout the long duration of the treatment, and his patience, courage and willingness to help us were most admirable and inspired us constantly in our efforts to improve his unfortunate condition. During the two years that he remained at the hospital he was subjected to six operations. He became attached to the service and rendered most valuable help as an assistant nurse, and in this way we were given a most favorable opportunity to follow his progress and the effects of treatment.

On May 30, nearly five months after the division of the cheeks and separation of the jaws, the patient had made so

Fig. 3.—Separation of the jaws after division of the cheeks and scar tissue on both sides; first stage of Jäsche's operation (from a photograph).

much progress and was able to take nourishment so well and masticate all foods that we decided to complete Jäsche's operation by finally closing the gap in the cheek and restoring the mouth to its normal dimensions. This operation was performed under chloroform anesthesia May 30. Chloroform was given on this occasion because there was no longer the risk that was associated with the administration of a general anesthetic in a case of constricted and trismic jaws. Had we

Fig. 4.—Second stage of Jäsche's operation. Two semilunar flaps are dissected from the cheek on each side of the oral cleft. These flaps remain attached to the gums and alveolar borders on each side of the cleft; the free edges are turned down from the cheek.

given a general anesthetic when the jaws were locked, and had vomiting, extreme salivation or bronchorrhea occurred, the patient would have incurred great risk of suffocation and death from a blocking of the larynx before we could have been able to divide the cicatrices and open the mouth. The choice of an anesthetic is therefore a matter of more than usual concern in such cases, and the advantages of local anesthesia by infiltration are well worthy of consideration. After the mobility of the lower jaw had been secured the

special risks of a general anesthetic were eliminated and we did not hesitate to administer chloroform, which the patient took quickly and well.

The second step of Jäsche's operation consisted essentially in cutting two semilunar flaps (Fig. 4) from the upper and lower margins of the buccal cleft, each flap extending at its fixed or attached portion from the angle of the mouth to the end of the newly-formed cheek gap. After dissecting these flaps they were turned into the mouth in such a manner that the epidermal surface faced the interior of the mouth and formed the inner lining of the cheek, the raw surface looking outward (Fig. 5). The fixed edge remained attached to the gums and alveolar processes; the free margins were sutured together with fine chromic catgut, thus forming a complete cutaneous partition which replaced the lost mucosa of the cheek, the diaphragm thus formed also acting as a barrier to the secretions of the mouth and preventing their entrance into the cheek wound. The external incision in the cheek was then readily closed by a series of interrupted catgut sutures (Fig. 6). This procedure was successfully applied to both cheeks and the mouth was restored to its normal appearance and dimensions.

The external wound healed per primam and the inverted flaps in the mouth united *in situ* in the right cheek, but the flaps of the left side sloughed away, in consequence, no doubt, of the defective vascular supply which held it to the gums

Fig. 5.—Second stage of Jäsche's operation, continued. The diagram shows the free edges of the cheek flaps sutured in the mouth to replace the lost mucosa; the raw surfaces look outward and are subsequently covered by suturing over them the raw edges of the cheek incision.

notwithstanding the long time that had been allowed to form nutritive communications (five months). This liability to necrosis of the flaps is no doubt the weak point in Jäsche's method of meloplasty in cases of this kind, when the flaps are cut off from the chief base of vascular supply and the nutrition of the skin is dependent solely on adhesions recently contracted with a cicatricial and poorly nourished base, such as usually exist in the scar tissue of the gums. In consequence of this unfortunate loss of the skin flaps on one side a secondary cicatricial contracture inevitably followed, and with it a partial relapse to the original condition of constriction that compelled us to resort to other expedients for the patient's relief.

From May 30, 1901, to Feb. 22, 1902, nothing further was done. The mouth and cheeks had healed completely and the patient was able to separate the jaws to some extent, but not more than half an inch in a vertical direction between the front teeth; the lateral motion remained improved, but was still greatly limited on account of the marked contraction of the left inner cheek, which had returned nearly to the condition existing prior to the Jäsche operation.

Therefore, in February, 1902, we decided that before undertaking any further plastic work with the view of correcting the remaining cicatricial contraction in the left cheek, we would increase the general mobility of the lower jaw by excising the right condyle and a part of the ascending ramus, leaving the coronoid attachment of the temporal muscle intact, thus making more space for the play of this muscle and the masseter, which were irremediably atrophied and shortened by early interference with the development and function of the maxilla.

The right temporomaxillary joint was excised and a large section of the ascending ramus of the jaw was also removed subperiosteally, leaving a considerable gap in the bone, which shortened the distance between the zygomatic arch and angle of the jaw on that side, thus approximating the points of attachment of the masseter and temporal without interfering with the periosteal attachment of the pterygoids. This wound healed kindly and without bad effects, as the branches of the facial nerve had been carefully protected throughout the operation. On the other hand, very little benefit was appreciable as far as the mobility of the jaw was concerned in view of the persistence of the cicatricial contraction of the left cheek, which prevented any exhibition of improved motion. Nevertheless, I have reason to believe that the extensive resection of bone at this point has been of value in favoring an increased mobility of the jaw by combining it with the procedures that were subsequently applied.

After this wound had healed we waited until April 21 before proceeding to the final operations by which we expected to completely mobilize the jaw. April 21 (two months after the excision of the right condyle), under chloroform anesthesia,

Fig. 6.—Jäsche's operation completed. The incision in the cheek closed by suture.

we again divided the left cheek along the line of the old cicatrix and at once a very fair separation of the jaws occurred, which gave us a gain of at least one and a half inches in the space between the front teeth. Fearing now that in spite of the splicing of a new and pediculated skin flap in the cheek that secondary contraction would take place, we decided to create a pseudarthrosis at the left angle of the lower jaw by excising a wedge-shaped piece of the maxilla at this point. This was done by Esmarch's method modified as follows: A horizontal incision about 2½ inches long was made parallel with the horizontal ramus of the jaw and terminating at the angle, around which it curved upward, gently following its contour. All the soft parts were cut down to the periosteum, and the angle of the jaw was divided subperiosteally without disturbing the tendinous attachments of the masseter or pterygoid. The angle of the jaw was completely separated from the rami in two sections, one vertical, through the horizontal ramus, and the other a cross section through the ascending ramus, by passing a Gigli saw subperiosteally around the jaw at these points. The periosteal capsule was then divided at this point and the severed bone sections were separately covered with periosteum. This procedure not only protected the exposed bone surfaces, but effectively prevented a future restoration of the continuity of the jaw at this point, the musculo-aponeurotic expansions of the masseter and the external pterygoid being sutured together in the interspace between the divided bone surface. The effect of this newly-created point of motion in

increasing the general mobility of the lower jaw was very marked indeed, and we felt confident that if we could only succeed in preventing the formation of a retractile cicatrix in the mouth that a permanent and satisfactory mobilization of the jaw would be obtained. Therefore, at the same sitting we undertook a plastic restoration of the cheek somewhat like the method suggested first by C. Gussenbauer in 1877, by which a long, well-nourished, pediculated skin flap dissected from the hairless part of the neck is transplanted into the mouth as a lining for the cheek. A flap 3½ inches in length by 1¼ inches in breadth was dissected from the neck and freely mobilized with its pedicle attached to the face close to the terminus of the gap in the cheek. The flap was turned on itself, and its entire edge was sutured to the inner surface

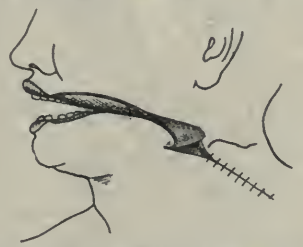

Fig. 7.—First stage of the modified Gussenbauer operation. The skin flap from the neck is turned into the oral cleft so that the skin edge is sutured to the inner raw surface of the cleft corresponding to the upper lip; the raw surface of the flap is also allowed to contract adhesions with the gum and cheek of the upper side of the cleft. After vascular connections have been formed the flap is turned completely into the mouth, as shown in Fig. 8.

of the vestibule from the angle of the mouth and along the inner border of the upper cheek flap. The lower edge of the transplanted flap was not sutured to the inner surface of the lower half of the cheek and the raw surface of the pediculated flap was thus allowed to come in contact with the thick raw surface of the upper half of the cheek (Fig. 7). Nothing further was done to close the gap in the mouth and this stage of the meloplasty was ended by simply closing the wound left in the neck after the transplantation of the pediculated graft.

The division of this plastic operation in two stages was adopted in this case because we were anxious to avoid the

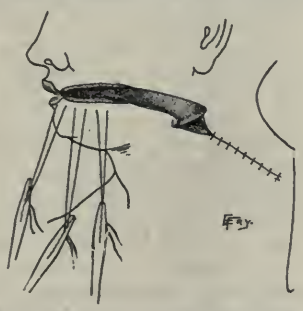

Fig. 8.—After firm adhesion has taken place, the transplanted flap is partially detached from the upper edge of the cheek cleft, leaving the gum line attached. The dermal surface of the flap looks into the mouth; the raw surface of the lower edge is brought into apposition with the raw inner surface of the lower cheek cleft. The two raw surfaces (of the cheek and of the flap) are brought together by a series of transfixion sutures (mattress type), which are tied externally over small pads of gauze.

risk of a second failure from sloughing, owing to defective vascular connections in the gums and mouth; we feared that in spite of the apparently abundant blood supply that came to the transplanted flap through its pedicle, that necrosis of its edges might occur from partial strangulation and infection if the flap was sutured in the mouth and the cheek closed over it. As a result of these precautions we had the satisfaction of seeing the transplanted flaps firmly united along the entire line of attachment to the inner surface of the cheek, where it remained in a well-nourished condition for the following six months. It was not until Nov. 22, 1902, that we undertook the final closure of the gap in the cheek, and this was done as follows:

The transplanted flap which had become firmly adherent throughout its attachment to the intrabuccal surface of the inner cheek was carefully detached from the cutaneous margin of the cheek cleft, leaving the upper skin surface of the graft attached to the gum and vestibule of the mouth. The lower half of the original skin incision was detached from the gum line and the lower border of the graft was inserted in the gingivobuccal groove and held firmly in place by a series of through-and-through mattress sutures, which held the raw surfaces of the graft and inner raw surface of the cheek in apposition (Fig. 8). The sutures (silkworm) were inserted with the Reverdin needle and the free ends of each suture were tied over a small pad of gauze on the outer surface of the cheek. After thus securing a complete apposition of the raw surfaces the cutaneous covering of the graft made a smooth lining for the inner surface of the cheek. The external incision in the cheek was closed over the graft by interrupted silkworm sutures throughout its length, except at its terminal (masseteric) end, where the pedicle of the graft was allowed to remain undivided, so as to insure its nutrition until a firm union had been obtained (Fig. 9).

Dec. 8, 1902, seventeen days after the cheek had been closed and no further doubt existed as to the vitality of the transplanted flap, and the success of the operation had been assured by the complete healing of the entire wound, we

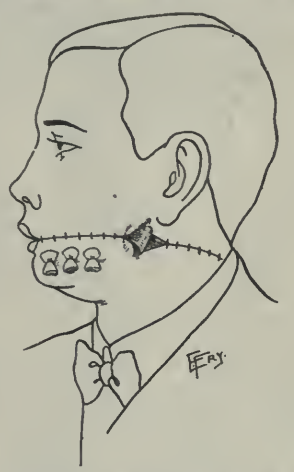

Fig. 9.—Appearance of face after suture of the cheeks in the modified Gussenbauer operation performed in this case. After suturing the cheek the pedicle alone remains to indicate the existence of the dermal flap, which has been transplanted from the neck into the mouth to replace the lost mucosa.

cocainized the pedicle and excised it, leaving a space at the terminus of the cheek incision, which was closed with a few catgut sutures. On the third day the wound had healed and the patient was well.

The patient remained in the hospital of his own accord until Jan. 8, 1903, when he was finally discharged to return home (Fig. 10).

Briefly summarizing the operative treatment of this case, we find that the patient was under observation at the hospital for a period of two years, from Jan. 15, 1901, to Jan. 8, 1903, and that during this time six operations were performed. The first operation (Feb. 1, 1901) was a complete through-and-through section of each cheek, including the division and incision of all cicatricial and ossified bands; separation of the jaws and suturing of the skin of the cheek to the gums, thus creating a huge oral cleft, or macrostoma (Figs. 1-3).

Second operation (May 30, 1901): Closure of the cheek gap by Jäsche's meloplasty. Third operation (Feb. 22, 1902): Excision of right condyle and part of ramus of the jaw. Fourth operation (April 31, 1902): Esmarch's cuneiform excision of the left angle of the lower jaw, to create a pseudarthrosis at this point; also

first stage of modified Gussenbauer's meloplasty. Fifth operation (Nov. 20, 1902); Gussenbauer's meloplasty completed by leaving pediculated neck graft in the mouth. Sixth operation (Dec. 8, 1902): Division of the pedicle of the transplanted flap and final closure of the cheek incision.

The final results obtained by these various operations and the protracted treatment associated with them was fairly satisfactory, and justified the sacrifices made by the patient in obtaining relief for what appeared in the start to be an absolutely irremediable condition. The chief object aimed at was to restore to the patient the ability to open his mouth, eat and chew food by increasing the capacity of the mouth and restoring the lost motion of the lower jaw. This object was to a large extent attained without entailing any serious sacrifice of his appearance, which had already been seriously affected by the disease. When he was admitted to the hospital the front teeth could not be separated to the extent of admitting the blade of a penknife introduced flatwise. When he was discharged he could separate his front teeth more than an inch apart. He could move his jaws laterally quite freely, and could eat and chew any ordinary article of diet without difficulty. While freely recognizing that all facial scars should be avoided in correcting deformities of this kind, it is evident that when dealing with a case of this type cosmetic considerations must be relegated to a secondary plane, and that restoration of the lost maxillary function must be given the prime consideration.

Fig. 10.—Photograph of the patient at the time of discharge from hospital. The pedicle had been divided and all incisions had healed.

DISCUSSION.

DR. JOHN B. MURPHY, Chicago—This condition of ankylosis is a most trying one for the patient and for the surgeon. I have had the good fortune to have two of these cases. One of them was the result of ulcerative stomatitis, which destroyed all the tissues of the cheek except the skin. The cheek was one cicatricial mass, and the muscles were destroyed clear back to the angle of the jaw. The treatment consisted of division of the fibrous mass and excision of the scar tissue on each side up to the base of the teeth. The first thing that was done after making the incision through the growth was the complete removal of the cicatricial tissue through the mouth. A flap was turned back from the neck below the chin, with its base below the ear. It was drawn into the mouth through a small incision in the cheek at the angle of the jaw, then turned on itself so that the skin came against the teeth and the raw surface outward. It was sutured above and below to the gums and iodoform gauze packed between the teeth and the flap, so as to make a perfect apposition between the cheek and the surface of the flap, thus placing the cutaneous surface of the flap on the inside. The result was excellent and without much disfigurement.

The second case followed the removal of a large angioma, which had left a large cicatricial mass so firm as to displace the teeth inward in a straight line. The teeth stood in a straight row from the angle of the left jaw to the right bicuspid. Through an incision from the angle of the mouth to the angle of the jaw I removed all the cicatricial tissue except the skin. Portions of the angioma still remained. I made the reverse type of flap from the skin of the neck, sutured the edges to the gums and closed the incision in the mouth; the cheek was packed with iodoform gauze. I succeeded in this last case, which I considered the more desperate, in getting a very movable jaw.

In neither case did we have the pain and other complications preceding the operation which Dr. Matas had in his cases, and I desire to compliment him on his work on these cases.

DR. J. R. EASTMAN, Indianapolis—I have had under my observation during the winter, a case of cicatricial ankylosis of the jaw which may be interesting to the members of the Section because of its rather unusual etiology. The case concerned a boy 7 years of age, who gave a negative anamnesis except that he recalled having fallen and having sustained what was described by his parents to have been a slight superficial injury at the angle of the right inferior maxilla. It was impossible for the boy to separate the jaws more than one-sixteenth of an inch, and he was therefore unable to take any other than liquid nourishment. It was also impossible to force open the mouth without using dangerous force.

There was a small scar and reddened area at the angle of the jaw. On making an incision over this scar and passing my finger along the ramus of the inferior maxilla I came on a hard object which proved to be a piece of wood one and one-fourth inches in length by one-fourth of an inch in thickness, jammed in between the ramus of the inferior maxillary and the superior maxillary bone. It was imbedded in scar and granulation tissue, which had become very dense. I removed the wood with a pair of forceps, and was immediately able to open the boy's mouth with slight force as wide as one-half inch. He has been able to chew food of all kinds, and I have not at this time advised further operation, though I am not unmindful that scar formation may make a plastic operation necessary.

DR. E. D. MARTIN, New Orleans—The last case recalls one of a severe head injury, where pus had dissected down on either side of the scalp until the masseter muscles were seriously impaired and cicatricial contraction followed. This case I was enabled to cure by a very simple device. I had made for him an apparatus resembling a glove-stretcher. This he carried in his pocket, and in his odd moments would put it between his teeth and with a little force succeeded finally in stretching his jaws to their full capacity.

If I had a case so complicated as the one reported by Dr. Matas I should not hesitate to remove the lower jaw. We

know how satisfactory the results are in cases where the jaw is removed for sarcoma, and especially when a temporary splint has been kept in position until the wound has cicatricized. This would preserve the orbicular muscles and give, in my opinion, far better control of the normal structures.

Dr. A. J. Ochsner, Chicago—I wish to call attention in connection with this discussion to one point which became apparent to me in one of my own cases. It is this: that a deformity of the lower jaw, and especially of the teeth such as that encountered in Dr. Matas' case, will disappear to a very great extent in growing children, if the operation is performed while the child is young. In an operation which I did on a child six years ago, within a year the lower jaw grew and the new teeth came in properly and the appearance of the child is now very nearly normal. I think it is better to do the operation while the child is still young, because the deformity can be corrected to a considerable extent, provided the jaw and the teeth are not hampered in their growth by the pressure which is due to connective tissue.

Dr. Rudolph Matas, New Orleans—There is no doubt of the great value of plastic flaps in operations of this character as substitutes for the lost mucosa of the mouth, though their value has been doubted by some writers. Without the skin, which is fortunately quite available in the vicinity of the mouth, there would be no hope of ever restoring the mobility of the jaws in grave cases of this cicatricial type. The cheeks, forehead or neck offer the best material for skin transplantation. The skin ultimately assumes the characters of the mucosa, especially when borrowed from normal hairless parts. I am much pleased that Dr. Murphy's experience has confirmed my own. Dr. Eastman and Dr. Martin have recorded interesting cases. Dr. Martin's mode of separating the jaws is valuable, but not applicable to cases like the one under consideration. His suggestion that the removal of the jaw would be expedient in a case like the one reported is entirely too drastic. It is impossible to conceive how excision could in any way better the situation of such a patient. There is no question that my patient's condition is infinitely better now with a plastic that yields restricted motion than without a lower jaw, or with an artificial jaw, as an artificial jaw, no matter how ingenious it might be, could never take the place of even a fragment of healthy maxilla. I entirely agree with Dr. Ochsner's remark that these cases should be operated on early to obtain the best results. I did not see my patient until he was 27 years of age, when permanent atrophic change in the bones and muscles had taken place and when developmental defects in the eruption of the permanent teeth had made the task of a perfect restoration a practical impossibility. Had the operation been performed twenty-five years before, I am confident very little traumatism would have been required to effect a cure. Nevertheless, when we consider the extreme conditions under which treatment was undertaken, the results must be considered highly satisfactory.

SURGICAL TREATMENT OF HIGH MYOPIA.

(SECOND PAPER.)*

H. V. WÜRDEMANN, M.D.

AND

NELSON M. BLACK, M.D.

MILWAUKEE, WIS.

In an essay delivered before the Western Ophthalmological and Otolaryngological Association at New Orleans, Feb. 10, 1899, and published by Drs. Würdemann and Murray in the *Annals of Ophthalmology,* April, 1899, the authors noted the rarity of high myopia in America and the relative frequency of this condition in the ophthalmic statistical reports of Germany and other European countries. A number of statistical tables were given in this paper which have been amplified and are herewith appended. These are taken entirely from the authors' private practice during the last fourteen years, in which 10,500 pairs of glasses have been prescribed, this, of course, including renewals of prescriptions. The following table shows the refraction of 4,690 eyes under a cycloplegic:

TABLE OF CASES UP TO JAN. 1, 1899.

Refraction.	No. of Cases.	Percentage.	Percentage.
Myopia	172	3.7	
M. As.	190	4.0	17.3
Comp. M. As.	451	9.6	
Hyperopia	1,148	24.4	
H. As.	512	10.9	76.7
Comp. H. As.	1,942	41.4	
Mixed As.	275	6.0	6.0
Total.	4,690	100.0	100.0

In addition to these there were 755 eyes fitted for presbyopia without the use of a cycloplegic.

The following table shows the refraction of 3,331 eyes and includes those in which complete examination under cycloplegic was made, and 861 eyes examined without cycloplegic in persons over 45 years of age:

TABLE OF CASES FROM JAN. 1, 1899, TO JAN. 1, 1903.

Refraction.	No. of Cases.	Percentage.	Percentage.
Myopia	110	4.45	
M. As.	56	2.26	16.02
Comp. M. As.	230	9.31	
Hyperopia	529	21.42	
H. As.	320	12.96	75.60
Comp. H. As.	1,018	41.22	
Mixed As.	207	8.38	8.38
Total.	2,470	100.00	100.00
Presbyopia	861		
	3,331		

Out of the above number of 7,160 eyes refracted under a cycloplegic there are only 282, or 3.9 per cent., of simple myopia; and including simple myopia, myopic astigmatism and compound myopic astigmatism there are only 1,209 eyes, or 16.9 per cent., with myopia. Of the total number of eyes refracted, 8,776, there were only 78 eyes of myopia over 10.00 D. (0.888 per cent.). Operation has been suggested in 4 instances and accepted in 3 (6 eyes), and the result in the 6 eyes operated on has been extremely satisfactory, although each operation was much more complicated than ordinary cataract extraction.

But few of the high myopic cases were adapted for operation, as the large proportion achieved comfortable and useful vision by proper correction of the refraction. It will be observed in most cases that the high myopia was accompanied by a considerable degree of astigmatism. It is likely that the many operations done for high myopia by our foreign confrères need not have been undertaken if they had corrected the accompanying astigmatism which was the greatest factor of discomfort. In other cases marked deviation of the visual axes existed, as is usually the condition in myopia (that of divergence). A marked example of the benefits derived from the correction of the full refraction and of the muscular deviation was the following case:

Case A.—Sister D. (a nun of Notre Dame Convent), Milwaukee, July 25, 1899, presented an unusual picture of very high myopia with internal strabismus. She was wearing, R.—15.00⌒ prism 10° base out; L.—15.00⌒ prism 10° base out, fitted by an optician. With these she had homonymous diplopia with the red glass of 25° and left hyperphoria of 4°. The full refraction was, R.—20.00⌒—1.00, 90°; V.=6/xxxvi; L.—17.00, V.=6/xxiv; by adding prism 10° out with prism 4° down over the R. eye and prism 15° out over the L. eye, monocular vision could be obtained, but with no combination of lenses could easy or useful vision be given to both or either eye and the patient preferred to do without any glasses. Op-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

erative work being suggested August 1, was accepted, the first step in which was to restore the visual axes to as near parallelism as possible; this being done by full tenotomies of both internal recti and advancement of the left external rectus. Monocular vision was immediately achieved, there being immediate exophoria of 2°. August 16 there was orthophoria in the distance; August 22, glasses were prescribed, R.—20.00⌒—1.00, 90°; L.—17.00, for distance and occasional use, and for the near was ordered, R.—16.00⌒—1.00, 90°; L.—13.00; for constant and near use. With these, to this date, she has had satisfactory vision and use of the eyes.

An example of the pursuance of vocation in high myopia without refractive correction, the patient refusing it, was the following:

CASE B.—March 7, 1892, M. D., age 40, seamstress; vision 0^2 counting fingers at 2 m., could read ordinary print by holding book very close to face, which posture she habitually maintained while working; had tried many times to get refractive correction. R.—11.00⌒0.50, 90°, V.=2/lx; L.—11.00⌒—2.00, 130°, V.=6/lx. These were ordered but were not tolerated; distance glasses changed later to R.—6.00⌒—0.50, 50°; L.—6.00⌒—2.00, 130°. Reading glasses were later ordered, R.—4.00, L.—4.00⌒—2.00, 130°, which were, as well as the other lenses ordered, asserted by the patient to be of no use. She has been under observation about every two years on account of recurrent deafness from inspissated cerumen and has tried no other glasses but gets along well in her business as head seamstress of a large department store and re-

fuses to try further correction of the refraction. In this case the patient prefers to utilize the blurred large images rather than the clearer smaller images given by correcting lenses, and as the myopia has not progressed during the dozen years she has been under observation, she has learned to adapt her blurred sight to her vocation and is otherwise a healthy woman. This is one of the few cases in which refractive correction may be dispensed with.

In the following cases the crystalline lenses were removed by operations:

Case 1.—Miss J. L., aged 20, born in Norway, resident of Manitowoc, Wis., recommended by Dr. J. F. Pritchard; came to the office July 6, 1897. She had worn several pairs of glasses on account of shortsightedness, but had received no satisfaction on account of the eyestrain which occurred when she wore them.

Family History.—Father had good eyes, died of yellow fever in middle life; mother living and in good health, has always had weak eyes, but never worn glasses, has had only the one child.

Personal History.—Patient had pneumonia at the age of 2 years and again at 11, has never been strong and is now anemic, has always complained of weak eyes, has found it very difficult to study, has been very nearsighted since adolescence, has been employed as house servant.

Examination showed a high degree of myopia with well-developed conus in both eyes; no opacities of vitreous; ophthalmometric measurement showed corneal astigmatism R—2.75, 90°; L.—2.25, 105°; the refraction was R.—17.00⌒2.75, 180°; L.—16.00⌒—1.50, 180°; for which the following correction was given: R.—16.00⌒—2.50, 180°, V.=6/xxxvi; L.—14.00⌒—1.25, 180°, V.=6/xxxvi; reduction of 4.0 D. from spheres for close work was given. These glasses were better worn than those which she had been wearing, but she was unable with them to follow up her ambition to become a dressmaker.

Operation for removal of the lens was advised June 15, 1898, accepted, and patient sent to the hospital. Following day, discission of right lens capsule under holocain anesthesia and atropin mydriasis; but little reaction. July 2, 1898, a second discission was done which caused considerable reaction, although the patient was allowed to go home. July 14 she wrote she had great pain, anterior chamber shallow, lens decidedly swollen.

July 26 she came to the hospital, lens greatly swollen, disintegrating and bulging into anterior chamber; tension +2; lens matter was removed by linear incision under holocain anesthesia. A clear pupil immediately resulting. Further course was uneventful.

September 16 ophthalmometer showed corneal astigmatism in the eye operated on of 2.50, 105°. With +1.00⌒+2.00, 115°, V.=6/xxiv; with addition of +3.50 sphere, Sn. 1.0 was read at 0.50.

September 17 the effect of the operation having been satisfactory in the right eye, a discission was done on the left lens capsule which at first was followed by no reaction, but two weeks later the lens became so much swollen that tension and pain occurred, so that it was extracted October 1 by linear incision, which was followed by clear pupil. Further course uneventful.

November 15 a secondary operation was done on the capsule remaining in the right eye. At this time the ophthalmometer showed corneal astigmatism for the left eye 4.25, 75°. The refractive condition was R.+1.00⌒+2.00, 115°; V.=6/xxiv; L.+2.00⌒+3.00, 75°, V.=—6/xxiv. With these she has binocular vision and with the addition of +3.50 spheres, for the near point, can read Sn. 1.0 at 0.50.

Patient has been seen or has written several times since and expressed herself as being very well satisfied with the improvement of vision and with the increased use of the eyes which she has obtained through the effect of the operation. Under date of Dec. 21, 1898, she wrote us "that she could see first rate in the distance but not so well near by." It may be that readjustment of the reading glasses will satisfy her more completely. There has been no tendency toward any other complication than that from the excessive swelling of the lens and to this date the eyes are in very much better condition than before the operation.

Later the patient returned to the office complaining of "black spots" before the eyes, especially the left. Vision with correcting lenses was 6/xv, R. and L. Ophthalmoscopic examination showed a disseminated choroiditis, most marked in the left eye—probably a result of the pathologic condition present before extraction of the lens. Visual field contracted in both eyes. The patient was given an alterative and advised to use the eyes as little as possible for near work. She has since been lost from observation.

Case 2.—April 28, 1900, Sister F. (a nun of Notre Dame Convent), aged 40; German descent, had been a nun for many years; high myopia and astigmatism, was wearing —11.00 spheres in both eyes fitted by local oculist; had had many pairs of glasses but had received no satisfaction on account of the accompanying eyestrain. Full refraction was R.—15.00 ⌒—3.00, 180°; L.—12.00⌒—1.50, 180°, which were ordered for her and likewise weaker pair for near use, but she was unable to wear any, preferring to do without glasses. Operation for the myopia was suggested and accepted, discission being done on the lens of the right eye May 18, 1900, and repeated six weeks later and subsequent discission of the capsule being made at the end of three months from the first operation when examination showed the eye to have the following refraction; R.+1.00⌒+1.25, 90°, V.=6/vi; October 27 discission was made on the left eye, and this repeated on Feb. 27, 1901, for opening of the capsule; April 30 the refraction of the right eye remained the same, while the left took +3.50⌒+1.50, 90°, with which V.=6/vi; +3.00 being added to this for the near gave comfortable reading vision. Aug. 26, 1901, there was no change in the glasses and the patient said she could see double with the left eye, which was evidently due to a strand of the capsule almost vertically across the pupil. This was discided, the irides were perfectly mobile to light and accommodation, the visual field was enlarged and the patient had satisfactory and clear vision.

Case 3.—Oct. 22, 1902, Sister R. (Dominican nun), aged 54, high myopia with cataractous changes in both eyes which had been going on slowly for four years; there were vitreous opacities and in both eyes myopia —18.00 D., for which she was wearing —10.00 D. spheres, but without satisfaction; had been unable to read for a year, and had consulted a number of oculists. We advised extraction of the lens, and October 29 discission was first made on the right eye, the lens being found to be hard and quite movable; November 1, simple extraction of the right lens was made, the pupil being left clear and round. November 25 there was thick secondary cataract, which was discided December 21. The refraction on December 22 was R. +1.75, 180°, with which V.=6/xxii, and with +3.50 could read Snellen 0.25 at 25. For some time after the extraction she had purple vision, which entirely passed away. Jan. 1, 1903, simple extraction was made on the left eye, which was perfectly normal, but was followed by considerable hyphemia, the bleeding of the iris persisting for over three weeks, but finally becoming resorbed, and as the patient had good candle field and could count fingers, at this date discission of the capsule was made, which, on March 7, gave vision 6/xxxvi with +2.00. March 25 R.—50⌒+1.75, 180°, V.=6/xii; L.+0.50⌒+2.25, 180°, V.=6/xxiv, with +3.50 she could read Sn. 1.50 at 25, R.—2.0 at 25, L; glasses ordered.

The results in all three cases have been most gratifying to the patients and the operators, despite their complicated course. In all cases we obtained the advantages which were shown in the paper read Feb. 10, 1899:

(1) Increase in the visual acuity; (2) enlargement of the retinal images; (3) enlargement of the visual field; (4) increased range for near work; (5) the wearing of light lenses instead of heavy strong spheric lenses, in a combination which permits of clearer and less distorted retinal images; (6) the pupil being brought

nearer the retina the eccentric visual rays are more excluded; (7) and most important, the more extended use of the eyes obtained by the patients; in all cases a new world having been opened to their view. Detachment of the retina has not occurred in any of these cases, and even if it should happen, the German statistics show that its occurrence is only in 5 per cent., and this is the percentage of cases of high myopia in which detachment occurs without operation. We will repeat the résumé given in our previous paper, which we have had no occasion to change:

RESUME.

1. Surgical treatment of myopia should be limited to those cases over —12.00 D. who suffer great inconvenience from their correcting lenses. The ideal cases for operation are those of —17.00 to —18.00 D.

2. The operation is mainly indicated in young adults.

3. Cases having active disease and changes in the ocular structures, such as progressive myopia, chorioiditis, fluidity of the vitreous or detachment of the retina are not applicable.

4. The dangers of operative interference are more than counterbalanced by the results to be achieved, which are mainly, increase of visual acuity and of the visual field, and more extended use of the eyes which accompany diminishment of the refraction.

THE CAUSES, PREVENTION AND MANAGEMENT OF MYOPIA.*

J. HERBERT CLAIBORNE, M.D.
NEW YORK.

In presenting this subject for consideration, I feel that it is neither fitting nor just that I should discuss every phase of it. It is my purpose, however, to draw your fire, and in this way to have the subject thoroughly ventilated.

In the beginning, permit me to say that I shall discuss the management of myopia in those who are under the presbyopic age, for I conceive that it is during this period that we are confronted by the serious problems in the management of the shortsighted eye.

The initial proposition which I wish to set forth is: that the condition of emmetropia is the normal and natural refractive condition of the human eye. It is true that infants, as a rule, are born hyperopic, and, therefore, it must be true that if they happen to arrive at the condition of emmetropia, an elongation of the eyeball along its anteroposterior axis occurs.

Emmetropia, therefore, under these circumstances, is an acquired condition. Now, if it is the purpose of Nature that all infants should be born hyperopic, it must be her purpose further either that the growth of the eye anteroposteriorly should cease at the moment at which the emmetropic length is attained, or that the final destination of the eye should be myopia.

Since no thing or condition in Nature is stationary, it follows that constant change in the length of the eyeball is natural, and that the condition of emmetropia is a fleeting and a transitory one. This line of reasoning places our philosophy almost in the realm of transcendentalism, and it is the basis of those who claim that the ideal eye is hyperopic; that emmetropia is a step, an intermediary one indeed, if not the first step toward myopia. I can not accept this interpretation as a practical basis, and I feel compelled to regard the emmetropic eye as the ideal one to which all eyes that differ from it should be reduced. This conclusion is not strictly logical, but is eminently practical, and is necessary in this discussion.

I regard the myopic eye as a vicious, diseased organ, with a constant tendency to increase in its anteroposterior diameter. It is likewise more subject to structural changes at its posterior pole than other eyes. It is a part of a reasonable therapeusis, therefore, to prevent the occurrence of myopia, to prevent its increase when it has occurred, or to reduce its increase to the minimum.

As has been stated, the physical cause of myopia is the elongation of the eyeball in its anteroposterior axis. The causes of this can be divided into those which are predisposing and those which are direct.

Permit me first to refer to the direct cause. I think it is safe to say that two theories are held on this point. One may be called the accommodative hypothesis and the other the convergence hypothesis.

Antecedent to the paper of Foerster, which appeared in *Knapp and Schwerger's Archives,* in 1884, the accommodative hypothesis had universal sway; but in 1884 Foerster set forth the reasonable claims of the convergence hypothesis as opposed to the accommodative hypothesis, in explanation of the cause of the development of myopia.

For my own part, I can not see how any one can adhere to the accommodative theory, either on the ground of philosophy or practical experience. In discussing the relative merits of these two theories, Foerster pointed out that if the elongation of the eye were caused by the muscular action of the tensor of the choroid, myopia would carry with itself its own infallible and invincible remedy; for the simple reason that work demanded of the accommodative apparatus decreases as the myopia increases. All this ceases the moment we look for the origin and increase of myopia in the excessive convergence of the visual axes. As the nearsightedness increases, the convergence of the visual axes increases, while simultaneously its claims on the tensor of the choroid decreases, which is practically the corollary to the initial proposition.

The persistent increase of myopia the moment it has attained a relatively high degree harmonizes, therefore, precisely with the increased angle of convergence. Foerster discarded the accommodative theory, and plainly pronounced himself in favor of the convergence hypothesis. His article contained the histories of a large number of cases which tend to support his views.

In convergence of the eyes for a near point there is pressure on the sides of the ball by the external muscles, and the nearer the object looked at the greater is the pressure. At the same time, there is necessarily a determination of blood to each eye, in conformity with that physiologic rule which demands the presence of a greater quantity of blood during physiologic activity than during physiologic rest. Unquestionably, then, these conditions might reasonably tend to produce myopia.

We are, perhaps, in some respects indebted to Von Graefe for the accommodative view of the cause of increase in myopia. He observed that in the effort to accommodate there occurred an increased pulsation of the retinal veins. He reasoned from this that the active condition increased interocular tension and thereby conduced to increase the length of the ball.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

That the eyeball itself should be increased in length by the act of accommodation in which there is a pull from the front on the back of the globe by an interior structure, is to me as unreasonable as that a man should be able to raise himself from the ground by pulling on his boot straps. I, therefore, accept the convergence hypothesis as the only reasonable one extant for the direct cause of increase in the length of the eyeball; and it is on this basis that I purpose to treat this subject.

It has been stated that the majority of eyes at birth are hyperopic. I think it is not straining a point to say that all eyes that are not macrophthalmic are hyperopic at birth. If the condition of myopia is to arise in these eyes, of course the condition of emmetropia is to be attained first.

Myopia rarely occurs in very early life; very rarely, indeed, does it occur under five years of age. And, in fact, I believe it can be said that in a large majority of cases it occurs after the child has commenced to use its eyes at school. The active study involves convergence of the visual axes; but I do not believe for one instant that this act alone will produce myopia. This reflection leads me to consider the predisposing causes of myopia.

I fancy no one will deny that myopia is particularly apt to occur in childhood after one or more of the exanthemata. I think scarlet fever and measles can be cited among these as claiming the largest number of victims. Subsequent to these diseases, the vitality of the patient is very much lowered. The entire muscular power of the body is diminished and, I think, particularly the accommodative power. The natural impulse to convergence degenerates into an effort. Along with that comes the congestion of tissues whose vitality has been weakened.

Most children are inclined to hold their books nearer than is necessary, and the younger the child, the nearer is the book apt to be held. The squeezing of the lateral muscles supplemented by congestion of naturally yielding tissues incident to childhood, fulfills the necessary conditions that favor the increase in the length of the eye. I cite the exanthemata because they, I believe, are the most frequent of the predisposing causes of myopia in childhood, and I cite them as types. Similar causes will produce similar conditions.

It is an accepted fact that heredity is a predisposing cause in the development of myopia. If a mother or a father in a family be myopic, and there are several children, myopia is most likely to develop in one or more of them. And it appears to be a fact, in my experience, that the mother is more apt to transmit myopia than the father.

Illumination and a proper text for books may be cited here. In schoolrooms the desks should be so arranged that the light, if possible, should always fall from the left, for obvious reasons. Moreover, the inclination of the desk should be such that the visual lines from the eyes when the head is held in almost an erect posture should strike the plane of the desk at right angles. This will obviate and possibly remove the habit so many children have of bending over their books.

This leads me to mention the importance of posture. The head should not be bent; it should be held almost erect; and the book, if it is read in the hand, should be held in front of the eye, and very nearly on the same plane as the eye.

The character of the illumination by night I conceive to be of the greatest importance. I can not condemn too strongly the use of the unfrosted electric bulb, which permits the eye to see the carbon wire. This, under all circumstances, will produce an after-image which is wearisome and irritating, and produces congestion of the entire ocular structures. If the electric bulb is used, and the bulb is within the field of vision, it should be at least frosted so that the carbon wire can not be seen.

I also desire to register here my condemnation of the Welsbach white light, which produces an exceedingly fierce light, in which I can not fail to detect some of the blue elements of the spectrum. This light is to me exceedingly disagreeable and produces distinct discomfort when used as an illumination for reading.

The best illumination for study, in my opinion, is the so-called German student's lamp, or the Argand gas burner, over which a green shade is placed. The source of illumination should be toward the left of the individual and below the level of the eyes, so that the light is reflected on the paper and again reflected to the eyes.

The slightly yellow light of the oil lamp, and even the Argand burner, give a wave length which is apparently grateful to the eye; and the further it is from the red end of the spectrum, without becoming green, the more grateful it appears to be.

The characteristic text of our schoolbooks and other books is gradually becoming larger and the linear spaces greater. There is to-day no longer any need or necessity for the small forms of print, and it will be an advantageous thing for the human eye when they have been relegated to the historic past.

I firmly believe that the high percentage of myopia in Germany is due as much to the universally abominable illumination there as to the German type. Luckily, nowadays, a large number of the German scientific books are being printed in the Latin text, and if the homes of the people could be illuminated so well even as the homes of our poorer classes, I believe there would be seen a diminution of myopia in Germany in the near future.

As a matter of course, an attempt to read in a reclining posture is a frequent cause of the increase of myopia. In this position there is the greatest possible strain on the lateral muscles.

Any general systemic condition which is inclined to cause congestion of the head tends to favoring the production of myopia; eminently, for example, constipation; and in early childhood this irregularity should be carefully watched and abated.

Owing to the vigilance and wisdom of our surgeons in this country, much has been done to prevent conditions at school and in home life which lead to the production of myopia in our children. A continued crusade along these lines will effect still more beneficent results.

Heredity, however, is harder to be combated, so far as it itself is concerned. But it behooves every intelligent surgeon who has under his care children with this predisposition to lay down the most rigorous rules for the care and conduct of the eyes of such children.

During convalescence from any form of sickness, children should not be permitted to go to school until all symptoms and signs have disappeared, and until they have regained their former strength and vitality. Even then their study should be graduated in quantity, and the number of hours of study should be cut down.

In this connection I can not refrain from condemning that which is so prevalent to-day in our schools,

namely, the making on children of demands inconsistent with reason and their ability, so that by the time a girl or a boy retires for the night, she or he has in one way or another employed the eyes from eight to twelve hours a day. Physicians should instruct parents and families in this matter; and the sight should be spared at the expense of useless and superfluous information. A fair amount of knowledge and perfect eyesight is preferable to extraordinary knowledge with strained eyesight and amblyopia.

The matter lies more in the hands of the general practitioner than in those of the specialist, for it is to the latter that the victim first comes.

Let us, then, assume that myopia has arisen in a child under the age of 15 years. What course should we pursue? So far as the correction of the refraction is concerned, three courses lie before us: the total correction of the myopia, the under correction, or no correction.

The total correction of this error is demanded on the convergence hypothesis, and is directly contraindicated on the accommodative hypothesis. Conversely, the under correction of the error or its non-correction is demanded on the accommodative hypothesis and contraindicated on the convergence hypothesis. Which one is to be pursued? It is fair to assume that that treatment is the best which is dictated by reason and fortified by statistics and authority.

I have already declared myself a distinct believer in the convergence hypothesis, and have given the reasons for my belief; therefore, by virtue of opinion I am compromised to the convergence hypothesis and the treatment by full correction. I shall not consider the question of non-correction at all. It appears to me that sufficient statistics have been compiled even at present in favor of the convergence hypothesis to demand the earnest attention of those who oppose it, if not to bring conviction, as to its correctness. The weight of authority, I believe, to-day is in favor of full correction. In the Heidelberg Congress of 1901, the majority of those present spoke in favor of full correction, and it is my ardent desire that a full discussion of this important subject should set forth the views of all those present. Dr. Edward Jackson has presented to this Society the result of his investigations along this line as far back as 1892. He reported the histories of 62 cases treated by full correction—the average period of observation for each case being about 5½ years. In these cases there were 123 eyes, one being blind with congenital cataract. During the above-mentioned period of time, 93 out of 123 eyes remained practically unchanged in the matter of refraction. In 10 eyes there was an increase, .50 D.S.; in 3, the myopia was diminished, .50 D.; in 13, the myopia increased more than .50 D., the average being 1.5 D.; in 4 eyes, the myopia was diminished more than .50 D., the average being 1 D. The visual acuity diminished in 6 eyes to a very slight degree; in 16 the visual acuity was markedly increased, and in a few it was doubled. These statistics have latterly been supplemented by others equally striking.

Over against these let us place those of Schreiter, Roscher and Meyerhof, in uncorrected or under-corrected myopia. Their patients were mostly under 20 years of age. Schreiter found less than 21 per cent. stationary in an average of 6 years of observation. Roscher found 39 per cent. of non-increase and Meyerhof 38 per cent. The latter two had their patients under observation for about four years. If one compares these statistics with those of Jackson, in which 75.6 per cent. remained stationary, such figures will carry their own weight and need no support.

These facts are supplemented forcibly by the statistics of Pfalz and Heine, presented at the Heidelberg Congress in 1901. The statistics presented by these men were overwhelmingly in favor of full correction. Fuchs, von Hippel, Axenfeld, Uhthoff and many others spoke in favor of full correction. When we remember that the former treatment of under correction or no correction of myopia found its greatest supporters among Germans, the incident becomes singularly significant.

Knapp has expressed himself in favor of full correction of myopia when there is good vision and no fundus changes present.

Over against this weight of evidence stands the views of Koenigshoefer, who is a strong advocate of under correction.

Liebreich has expressed some original views as to the physical cause of myopia. He considers it due to increased interpupillary distance caused by a separation of the orbits. He claims that this osseous malformation produces a disturbance in the correlation between accommodation and convergence which, of course, causes an increase in the angle B. He thinks total correction achieves good results only in those cases in which the angle B is either very small or normal.

It is safe to say that sufficient statistics have not been brought forward in this matter, and herein is a loophole for the disciples of under correction. It is hoped that the interest in the matter will be so stirred that careful statistics of all cases of myopia under treatment will be compiled, and the principles at issue be settled beyond peradventure.

Widmark of Stockholm has called attention to the influence of corneal opacities in causing an increase of myopia when it is present or its production when astigmatism is associated with the opacities. He has observed, however, that the production of myopia or its increase generally occurs in that eye which is free from opacities, and in case there is astigmatism in each, he has observed that myopia arises in the less astigmatic eye. While he favors the convergence rather than the accommodative hypothesis, he conceives that myopia produced by opacities of the cornea, as above described, can not be explained on the convergence hypothesis. It appears to me that his observations were strong proof in favor of the convergence hypothesis. The opacities in the cornea induce the patient to hold the work nearer to the eye; this perforce increases the convergence of the visual axes and excessive congestion of the better eye—ideal conditions for the production of myopia on the basis of the views expressed in this paper. His conclusions seem to me to negative his reasoning and his observations.

Foerster concluded that three things were necessary in correcting myopia; the first was a full and proper correction, the second, the proper position of the eyes in work, and the third, the use of abducting prisms to force the near point outward in binocular vision.

The first two propositions are eminently reasonable, but the third I consider superrogatory, and this latter suggestion of his is characteristic of all those who propose new ideas. It seems reasonable enough that there should be a full and complete correction, but the use of abducting prisms points, in my opinion, lies in the direction of overdoing the matter.

For my own part, I regret I have not kept my records carefully enough to enable me to back my opinion, concerning the full correction of myopia, by statistics. Yet, after all, statistics are in many ways deceptive because it is practically impossible to collate uniformly similar cases. The weight of the evidence, in my experience, has been overwhelmingly in favor of full correction, though I do not think the rule can be said to be hard and fast.

I commenced to give the full correction in myopia in 1886, and I have continued to do so under proper conditions to this date. It requires no patriarchal experience to remember the day when the full correction was never given and when even the myopic laity entertained definite views on the subject. To-day at times one meets patients who still give some evidence of their attachment to those views.

It has frequently happened to me to be compelled to combat these views in the mothers and fathers of children—so strongly and widely was the old idea of under correction promulgated by the elder practitioners. It is not possible for me to say to what degree I correct myopia in all cases. Each case I consider a law unto itself. I have known some people, even adults, who accept and wear with perfect ease for distance, glasses which would not for a moment be tolerated by another with an equal error.

Suffice it to say, I correct myopia in children to the limit, if possible, and I force them to wear the glasses for reading and for near work. I consider this necessary in low degrees of myopia as well as in high. Now, I do not mean that every individual should be forced to wear the full correction glass which is indicated by retinoscopy or the direct method, but he should be made to wear the weakest glass found by the test case with which he gets the best vision with the most comfort; this I consider full correction.

It is obviously absurd to force on a patient a correction which is estimated by objective methods of examination alone. The functional method with the test case is the crucial test, and its decision should guide us. There must, however, be a reasonable relationship between all methods.

In those cases in which the degree of myopia in the two eyes differs considerably in amount, it is my custom, as a rule, to give the glass which corrects the less myopic eye to both eyes. I find that this is uniformly more agreeable than correcting each eye separately. This can hardly be said to be full correction in a true sense, but it amounts to that, and is in the way of my rule, viz.: the weakest glasses which give the best vision with the greatest comfort to both eyes.

Of course, the far point should always be thrust as near as possible to infinity, i. e., to say to twenty feet. But in the majority of cases it is not well to give the stronger glass if a weaker glass will give the same visual result, because the sharper visual image furnished by the stronger glass causes the patient discomfort. I do not believe that the cause of this lies in the increased accommodation. I believe it is an inherent quality in some retinæ. It is obvious, then, that the weakest glass which gives the best vision compatible with comfort is the strongest glass which will be tolerated. I am accustomed to ask the patients if the glasses feel "soft." This word seems to convey the proper idea to them. There seems to be a uniform conviction that full correction ought not to be worn where fundus changes, particularly choroidal ones, are present. For a long time I held this to be an exception to my views of full correction, but one case which I shall relate has caused me to give as full a correction as possible in many of these cases.

A woman, aged between 35 and 40, had a high-graded myopia with extensive posterior staphyloma in each eye and marked changes at the macula in the left eye. She had been under the care of a surgeon in a neighboring city, who held the old views about the correction of myopia. He cautioned her against any correction at all, but gave her a weak pair of lenses with which she could see very little better at a distance than without any, and told her to read without glasses. She could not enjoy the pleasures of reading, nor the theater, nor could she go about the streets by herself without great danger. This had persisted for at least ten years. The loss of sight, and particularly detachment of retina, was held up to her as a check on her ambition to be more comfortable, and so she sat and held her hands. In her right eye she had 20/30 vision with —11 D.S.⌒ —1. S.D. with ax. 90°; in her left, 20/200 vision, with —11 D.

After the use of atropin for a week, I gave her the above correction for distance, and at the end of another week I gave her a reading glass; in the right eye, —7 D.S. ⌒ the cylindrical correction, and in the left, —7 D.S. She tolerated both glasses well and has worn this correction for five years. At first I demanded she should increase her reading gradually in this wise: the first day she was to read fifteen minutes, the second 30 minutes, the third three-quarters of an hour, and so on until she had attained two hours of steady reading. I was rigorous in this particular, and I customarily give these instructions to cases in which there is a high degree of myopia, and in which the full or the best possible correction has not been worn before. This lady, emboldened by the ease and comfort with which she sees far and near, has regularly taken each summer since a course at a summer university. Her whole method of life has been altered, and she is grateful. She was of uncertain age and so I gave her a reading glass. If she had been ten years younger I verily believe she would have accepted the same glass for distance and reading. Before the correction she was wont to have photopsies and muscæ volitantes. These symptoms practically disappeared under correction.

I am inclined to think that some lay too much stress on the matter of choroidal changes in the correction of myopia. I believe it is always well to proceed with such cases cautiously, and it is my custom to use a mydriatic for some time before prescribing, but I do not believe that the tension on the choroid necessarily caused in the act of accommodation has so serious an effect as is ordinarily believed. This case supports my views on this point fully, and I have had many similar ones in my practice.

As to the use of a mydriatic, I hold that it is well in all cases of choroidal lesion to employ atropin sulphate, and when the eyes have been kept in a condition of physiologic rest for an appropriate time to discontinue its use, and give the correction according to the principles I have set forth.

As to the use of homatropin, it is my custom to use this agent in simpler cases in which there is spasm of the accommodation or the asthenopic symptoms are particularly marked. I believe that the use of a mydriatic in all cases is not necessary. I also believe that a skillful ophthalmoscopist can, in the great majority of cases, adjust the glasses correctly without its use. *Per contra,* I believe the use of homatropin in every case will do no harm, and will lead more nearly to a correct adjustment. In some way I conceive that the constant and uniform use of homatropin is a refuge for the unskillful.

It is always my custom to make first an approximately quantitative diagnosis with the skiascope, to cor-

roborate it by the direct method, to scour the fundus with the indirect, to use the ophthalmometer next, and to hold all these methods in check by the test case. The correction by the skiascope alone is not practical, in my opinion. I place very little faith in this method alone, as a quantitative test. It takes too much time, is wearisome to the patient and the surgeon, and is open to other objections which it is not my purpose to set forth here. As a qualitative and an approximately quantitative method of examination, I consider it of the greatest service, but I never correct by it alone, nor could I rely on it against the findings of the other methods.

As a means of discovering the approximate axis of astigmatism, I have quite as much faith in it as I have in the ophthalmometer. In clinical work, I am accustomed to use Placido's disc, but I hold behind the aperture in one hand a + 4 D. spherical glass. As a rapid method of diagnosing the approximate axis in astigmatism, I consider this is exceedingly useful.

I conceive that in the correction of myopic astigmatism, as in spherical myopia, the weakest glass which affords the best vision, consistent with comfort, is the correct one to give.

I think, then, it can not be said that all cases of myopia, whether spherical or astigmatic, can or should be fully corrected, and in using the term, "full correction," or in advocating the principle, I desire to be understood as advocating the use of the weakest concave glass which gives the best vision and is, at the same time, compatible with the comfort of the patient. This, it will be observed, is distinctly adverse to habitual under correction, or no correction at all, and is consistent, in my opinion, with the principles involved in the convergence hypothesis.

I think I may sum up my views on this subject in the following manner:

1. Myopia is a condition in which there is an increase in the anteroposterior diameter of the eyeball. This condition is, except in very rare cases, acquired. It is a distinctly vicious process, and in the great majority of cases tends to increase. It should, therefore, be regarded as a disease. It usually begins in childhood.

2. Its causes may be divided into predisposing causes and a direct cause.

3. (*a*) The predisposing causes are, in general terms: Heredity, naturally lax conditions of the eye tunics in certain individuals; the injudicious use of the eyes after sickness, usually in children, after the exanthemata; bad illumination, improperly placed illumination, incorrect position in the act of reading; the existence of refractive errors, generally astigmatism, which is uncorrected or improperly corrected; corneal opacities; any systemic condition which tends to produce cerebral congestion, for example, constipation.

(*b*) The direct cause is an elongation of the eye on its anteroposterior axis, at the posterior pole, except in the case of corneal astigmatism.

4. When myopia has once been acquired, its increase is directly caused by the pressure on the globe by the extrinsic muscles, due to the convergence of the visual lines toward the far point—the convergence theory.

5. The weight of evidence and reason is distinctly against the accommodative theory.

6. Theoretically, full correction of the myopia is indicated, whereby the far point is thrust to infinity.

7. Practically, this is not always possible.

8. The far point should be thrust as far as possible toward infinity, but, at the same time, it should be compatible with the best vision and the greatest comfort.

39 West Thirty-sixth Street.

DISCUSSION

ON THE PAPERS OF DRS. WURDEMANN AND BLACK AND CLAIBORNE.

DR. EDWARD JACKSON, Denver—No fixed rules can be laid down, in my opinion, as to what cases are suitable for operation and what cases are not, and a very definite opinion on the advisability of operation can not be given in any case until it has been repeatedly seen and studied and the test lenses tried. I have so often seen lenses of 18 and 20 diopters worn with comfort for years that my experience with removal of the clear crystalline lens has been very small. I think, too, that the contraindications can not be stated very definitely, as any rules will have so many exceptions that they will lose the value of rules. Fundus changes are not necessarily a contraindication. If they are so extensive that perfect focusing of light on the retina will not give any improvement of vision, probably there would be no reason for an operation. If the eye is not in a good condition for operation, as having a recent choroiditis, or recent hemorrhages, an operation should not be done at that time. With reference to the vision, we can expect a certain improvement from the effect of bringing the nodal point forward from the retina by the operation; and that becomes a very important indication in cases where the acuteness of vision can be brought up by lenses to 1/6 or 1/8. If you can get vision of 1/6 or 1/8 with the lenses and the operation is successful and the case goes smoothly, there is a probability of bringing up the vision to a point where it will be very useful. Vision much lower than that, however, may be improved so as to be of great benefit. As to the effect of operation on refraction, it may be expected to increase for some months and sometimes for some years afterward. If myopia remains it will be still further reduced and if hyperopia, it will become greater. That corresponds to what occurs in cataract extraction. Diminution of refraction goes on after the changes of astigmatism have ceased. As to the methods of operating, one point should be emphasized; that is the care in making a moderate or small discission to commence with. While the effect of this on some eyes may be very slight and may entail some waiting, it is a great deal safer. I have had to take out for sympathetic ophthalmia an eye that had been lost by an operation for the removal of the lens. While I did not do the original operation, it was a free discission and was followed in twenty-four hours by severe swelling. Of course, if one be prepared to deliver the lens at any time after discission the serious damage may be obviated. Still after acute swelling the eye is not in as good condition for the removal of the lens as when the lens has been allowed to become opaque slowly. If the lens must be removed as soon as possible, it is better and safer to remove it without any discission whatever, even though a subsequent operation has to be done.

DR. A. B. HALE, Chicago—In my clinical work about 38 per cent. of the cases are myopic, as many of them are Russians and Poles. I have ten cases of operation that I have not yet reported in which the results have been very good. Where Dr. Black gives the percentage he forgets that many cases of postoperative prolapse do not go into the records at all. I saw six cases last summer of postoperative prolapse that were not reported and heard of six others. Axenfeld, in a personal letter, says that he is not satisfied with the reports for the first six months, but is inclined to wait for one and a half or two years, as he had one prolapse two years after operation. I think we must accept statistics with a little less cheerfulness than they are presented to us.

DR. H. D. BRUNS, New Orleans—In about 2,500 cases of refraction I have operated seven times for the removal of the lens in high myopia. I reported three of these in the *American Journal of Ophthalmology*, 1898 and 1899, under the heading of "Cases from the Clinic." It seems to me that the greatest value of the operation is prophylactic. There is little chance of keeping a very high myopia in a young person stationary and we

have the greatest opportunity to rescue these individuals from helpless middle age, with the oncoming of cataractous changes later; and we all know how unfortunate operations on such cataracts are. All of my operations but one have been in patients under 18 years of age; that exception confirms what was said a moment ago about certain pathologic changes not being a contraindication. The discission was done to relieve the dull, incessant pain of a highly myopic eye with posterior staphyloma in a woman of 35. I operated in 1897 and the patient some years afterward was entirely free from pain, the disease had made no further progress and she was well satisfied with the result. I agree fully with what has been said about the moderateness of the discission and I think it holds true of all discissions. It is well to make a small discission and wait to see how the eye will tolerate it. I prefer safety with length of time to the loss of a well-seeing eye which I have counseled the patient to have operated on for his future good. That makes the loss of an eye a calamity indeed. The only case in which there was a bad reaction was one operated on by one of my assistants, which had to be extracted. The lens was too much broken up in the discission. A month of iridocyclitis followed. The patient was a little child 12 years of age with good eyes, except that she had 14 diopters of myopia, and I experienced such a bad 30 days that I have never since been tempted to try to gain time at the expense of absolute safety.

Dr. Melville Black, Denver—It seems to me that Nature makes a strong effort in high myopia toward prophylaxis that should be recognized. There is a tendency in all these cases to divergence due to inability of the interni to swing the eyes in. It would seem to me that it is well to recognize this effort on the part of Nature and not try too much to overcome it by giving the patient binocular single vision. I operated recently on a case with 20 diopters. It will not be my policy to operate on the other eye, for I prefer to have in this case as much disassociation of the eyes as possible. It will be impossible in this case for the patient to use the eyes together. I have given nothing for distance over the eye operated on, but have corrected the other eye by a minus 14 diopter lens, which can be worn for near work; thus the patient uses the eye operated on for distance and not the eye operated on for near work. I think that will tend to reduce the probabilities of increase in the myopia.

Dr. J. F. Fulton, St. Paul—I am so pleased with the results of discission that I do not see why extraction should ever be attempted. It is wonderful how rapidly the lens will be absorbed. Success consists in being extremely careful in the original discission. After that you can tear up the anterior capsule freely. The few cases I have operated on have been extremely satisfactory.

Dr. H. Moulton, Ft. Smith, Ark.—I believe in the full correction of myopia, but in cases in children we must secure the coöperation of the parents. Many parents do not do enough close work to understand or appreciate the insistence on suitable light and places of study for the children. It is difficult to get them to follow out our directions properly.

Dr. Oscar Dodd, Chicago—For the last few years I have been correcting my myopic cases in full and find that they are not only more comfortable, but, in following them up and having them come back for examination every six months, I find that nearly all remain stationary, while those cases I have seen which were not fully corrected made much greater changes. One point to be insisted on, I think, is the careful correction of the astigmatism. I had a case of high myopia not very long ago a man 39 years of age, that had been refracted by an oculist ten years before. In the course of a year he lost his reading glasses and had worn those intended for distance, —20 D., all of the time. I found that he took a —22 D. in one eye and —24 D. in the other to see in the distance sufficiently well to read the names on the street cars. I advised removal of the lenses, but at his age I was careful about promising a good result. He preferred to get along with an occasional use of the distance glasses.

Dr. G. E. de Schweinitz, Philadelphia—In all important particulars I agree with Dr. Claiborne. I believe that young persons under 25, with good vision and a moderate degree of myopia (under 6 D.) should wear the full correction of their refractive defect constantly, if accommodation is ample and no signs of fatigue are present. The same rule is applicable to patients until they reach those years when accommodation must necessarily receive help, or when examination shows that the amplitude of accommodation is not equal to the necessities of the patient's life. I agree with Dr. Jackson that full correction is the object to be attained for young persons with normal visual acuity and binocular near vision, no matter how high their myopia, provided the lens selected shall not be an over-correction when brought close to the eye. I fully understand that there are many exceptions to these rules, and that each case must be studied and decided on its own merits, but other things being equal I consider it a positive misfortune that when young people first come for the correction of their myopia they are so frequently given the so-called under-correction, because once under-correction having been given, it is difficult to alter it to a full correction, and a full correction, within the limits already stated, is the best safeguard against the increase of myopia, when worn with proper regard to the hygiene of the eye and the body generally. My experience in the removal of the clear crystalline lens for the relief of high grades of myopia has been a limited one, but entirely favorable. I have always operated by discission first, followed by extraction. The really brilliant results which I witnessed in Dr. Bruns' clinic to-day have well-nigh persuaded me, however, to pursue his method of repeated discissions.

Dr. Leartus Connor, Detroit—All school children are subject to about the same conditions, and yet only a few develop myopia. Why is it? My explanation is that some unknown factor of nutrition exists in the eyeball in these particular persons by which the disastrous results develop. We should, of course, endeavor to remove these so far as we can.

Dr. Allen Greenwood, Boston—I think these cases should always be refracted under the complete mydriasis of atropin.

Dr. John E. Weeks, New York—Although the accommodation theory may not, perhaps, be logical, certain cases come before us that are difficult to explain in any other way. I have in mind a family of five, the father and four children. The father had a myopia of 10 diopters with astigmatism of about 2.50 D. in each eye, with some floating opacities in the vitreous. The oldest son had a myopia of about 5 diopters with astigmatism of 1.50; the child next in age had a myopia of about 2 diopters with some astigmatism; the third, hyperopic astigmatism of 1.50 to 2 diopters, and the fourth, hypermetropia with astigmatism. In each case there was progressive posterior staphyloma. The error of refraction was corrected as completely as possible. This was about seven years ago. The father died about three years after the examination was made and his myopia had not increased. The children have been under observation ever since, and with the exception of about .50 diopter in the oldest boy the refraction has not changed. This is not an isolated instance in my practice. I have not infrequently found that the correction of the error of refraction arrested the process in cases in which staphyloma posterior or sclerochoroiditis posterior was progressive. Although convergence may be chiefly instrumental I do not believe it is the whole cause. As to the removal of the lens in high myopia, I have operated a number of times; I shall hereafter operate by small discissions at first. I shall do a linear extraction only in those cases in which I am compelled to do it. It is, as Dr. Bruns has said, a great calamity to lose an eye after advising removal of the clear lens. Operation by discission and subsequent linear extraction is safer than primary extraction.

Dr. N. M. Black, Milwaukee—I thoroughly agree with Dr. Bruns in doing small repeated discissions and not attempting linear extraction unless indicated; one exception, however, can be made, in the case where the lens is becoming cataractous; in that case linear extraction is justifiable. As to operating where there is disease of the fundus I think the patient should first undergo a certain amount of treatment.

Dr. J. H. Claiborne, Jr., New York—Dr. Thompson taught the full correction of myopia some twenty years ago. I was not aware of that until Dr. Bruns called my attention to it in

a note just now. I thought Forster was the first. As to Dr. Connor's question: I made mention of a case in these words "a relaxed condition of the tissues peculiar to some people." The negro has a characteristic expression for conditions of this kind, "slack twisted people." Such are persons of low vitality who are placed in unfavorable conditions. Some one has suggested that there should be full correction always under atropin. It is clear to me that if you take the refraction under atropin and then without you find a considerable difference. The eye will be more myopic when the atropin has worn off because there is a tonic action of the ciliary muscle that we can not get rid of. I can not accept that proposition as an absolute truism. I have observed a habit growing among ophthalmologists in speaking of "refracting patients," and I want to put myself on record as opposed to it. A patient may be refractory, but can not be refracted. We should eliminate that expression from our nomenclature.

RESEARCH PROBLEMS OF PHARMACOLOGY.*

TORALD SOLLMANN, M.D.
Associate Professor of Pharmacology, Western Reserve University.
CLEVELAND, OHIO.

The main object of pharmacology is to supply a basis for rational therapeutics. The entire medical profession has always been in accord as to the desirability of this end, but the methods of pharmacology did not at first secure universal recognition. This prejudice against laboratory experiments has now practically disappeared, partly through the advance of medical education and partly through mutual concessions. The modern physician realizes that rational therapeutics can not be based solely on bedside "experience," with its hastily and imperfectly observed and digested data. The phenomena in question are altogether too complex to be understood by such primitive methods. They need to be studied by the most delicate and profound methods over which modern science disposes. This study constitutes a large part of the research problems of pharmacology.

PRACTICAL PROBLEMS.

These problems, which pharmacology must investigate in regard to every used drug, before rational therapeutics can rest on a sound foundation, are broadly as follows: The immediate and late, the direct and indirect, modifications produced by varying doses of the drug in every structure on which it may act, intentionally or accidentally; these actions as manifested in disease; the cause of these actions; the fate of the drug in the body; the chemical constitution of the drug; the effect of the constitution on the action; the possibility of modifying the constitution of active drugs and with this their action, with consequent improvements in the drug; and, finally, the effect of the simultaneous presence in the body of this drug with others.

Almost every pharmacologic research deals more or less directly with one or another of these questions, and considerable has been accomplished in this direction. The results are, however, altogether too scanty. To realize how far we still are from a satisfactory solution of these problems, you need only examine critically our present knowledge of even the most commonly used drugs, such as strychnin, and you will see that not one of the above questions is answered as fully even as our present experimental means permit. It is well to recall that we do not even know wherein the members of a pharmacologic group—such as the digitalis group, the bitters, the cathartics—differ from each other. As a further instance of our limited knowledge of very important points, it must be confessed that we know very little of the late changes produced by drugs and of the reactions which must in many cases follow their actions.

PROBLEMS REQUIRING CO-OPERATION WITH OTHER MEDICAL BRANCHES.

To obtain satisfactory solutions of these problems, pharmacology must undertake, in the first place, a more detailed study of the therapeutic and poisonous actions of important remedies, such as aconite, alcohol, antipyretics, antiseptics, arsenic, caffein, cathartics, cholagogues, dietaries, digestive ferments, digitalis, diuretics, ergot, gelatin (as hemostatic), hydrastis, iodids, iron, mercury, quinin, strychnin, saline infusions, etc. These should be investigated not only by laboratory experiments, but also on carefully diagnosed and observed cases at the bedside. For this a correct diagnosis and understanding of the pathologic condition are prerequisite, and the slow progress of therapeutics is partly due to the deficiencies in this respect, deficiencies which the leaders in these branches are the first to acknowledge. However, it should be possible, even with the present conditions, to so state the problems to be investigated that the answers should be clear and decisive, and that the results of different observers would be comparable.

It is in this connection, in directing and co-ordinating clinical inquiries, that the older, experienced practitioners could do invaluable service in advancing pharmacologic research. Very great benefits are to be expected from the reorganizing hospitals for this purpose, for there are at present very few hospitals in which the experimentalist can co-operate with the clinician. As an instance, there are very few which have the laboratory facilities to make the most ordinary observations on metabolism; nor have they on their staff any men practiced in such work, or even nurses or orderlies who are trained in collecting the material properly. The limits of the thermometer, microscope, hemoglobinometer, hemocytometer and thermostat; and of test tube and burette work, have been pretty well exhausted. To make real advance, the hospitals must have added facilities, and must have a man or a staff who can devote themselves to the scientific work, without distraction by routine duties lying outside of the scientific scope.

This would also give opportunity for applying pharmacology to the investigation of the nature of disease. It must be remembered that both in pharmacology and in pathology we deal with altered cell metabolism. It is often merely a matter of convenience under which science we class a given phenomenon. Toxin-tetanus, diphtheritic paralysis, diabetic coma, and many other forms of disease are strictly intoxications. The methods used in their investigations must be essentially those which have proved so fruitful in the pharmacologic laboratories. All the diseases due to toxins, as also uremia, scurvy, rickets, gout, nephritis, indigestion, etc., need to be investigated in this spirit. This fact is not yet sufficiently appreciated. Natural and acquired tolerance to poisons is another subject in which the pathologist, clinician and pharmacologist can co-operate; but in this field pharmacology is particularly behind. We know less about the mechanism of tolerance in the case of drugs, as morphin, nicotin, alcohol or atropin, than in the case of bacterial toxins—although even here our knowledge is not exhaustive.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. S. Solis-Cohen, George F. Butler and N. S. Davis, Jr.

Considerable progress has been made in the way of replacing crude drugs by their active constituents. However, we know but very imperfectly the active constituents of some very important drugs, as digitalis or ergot. Methods should be devised for the practical isolation of these in active and stable form. Other plants, not as yet in common use, may also contain valuable ingredients. The usefulness of active constituents in general could often be greatly increased by modifying undesirable characters, as instability, solubility, rapidity of action, side actions, etc. There can be no doubt that the actions of a drug depend on its constitution, and can be altered with this. Here the chemists do us a great service by modifying the constitution of drugs in almost any manner which we may desire. It is the office of the pharmacologist and of the clinician to ascertain the effect of these modifications. This has been done in many cases to the great advantage of therapeutics. The small book of Fraenkel, *"Arzneimittelsynthese,"* gives very interesting proofs of this statement. It does not seem too much to hope that we may eventually be able to dispense entirely with vegetable drugs, and to produce artificially the identical constituents which we now use, and in many cases improvements on these.

This era seems, however, still very distant; we must for some time put up with the disadvantages incident to drugs derived directly from the organic kingdom. But here also great improvements are to be effected, and this offers an alluring field for the scientifically trained pharmaceutic chemist. The present pharmaceutic preparations are, in many cases, far from ideal. They often contain useless and even undesirable constituents, are unsightly, of bad odor and taste, inconvenient and prone to alteration. One of their most unsatisfactory features consists in their uncertain strength. This should be speedily remedied by suitable assay processes, chemical or "physiologic." The subject of physiologic standardization needs thorough investigation to determine the limits of its usefulness, and to establish proper official standards. When reliable assay processes have been elaborated, a great deal can be done in improving crude drugs by cultivation, selecting proper varieties, determining the best season for collecting, etc.—as is now done in the case of cinchona and of the sugar beet. Cultivation should produce a more steady supply of a higher and more uniform quality.

METHODS.

There is no dearth of problems which may be solved by the experimental methods now known to us. However, investigation directed to the improvement of old, or the elaboration of new, research methods constitutes a very useful field of research. Every advance in this direction brings with it large additions to our knowledge, by opening up new problems, or by making research more exact, more easy or less costly.

THEORETICAL QUESTIONS.

I have attempted to lay before you some problems, the solution of which would have an immediate bearing on the questions of everyday practice. Every successful research, in answering some questions, raises others. Every explanation requires further explanation, until we face the question: what is the ultimate nature of the phenomena of life? This, the ultimate question of all biologic sciences, needs to be answered before biologic problems can be said to be thoroughly understood. But just as the science of physics is not rendered useless by the fact that it can not explain the nature of matter or of force, so the science of medicine is not rendered useless because it has not yet answered its ultimate problems. We can not afford to lay medicine aside until the biologist has finished his investigations. While we are seeking to solve the puzzle of the "ultimate question" we must be content with finding partial solutions to practical questions as they present themselves.

Both lines of investigation are open, and research may be directed either to immediate practical problems, or it may deal more or less directly with the ultimate questions. However, the two are so closely interrelated that every result in one direction aids also in the other. It is, therefore, quite possible to keep both objects in view. This will broaden the work, and will make it more immediately useful. The history of science shows abundantly that achievements in abstract directions are by no means incompatible with the duties of a practicing physician, much less with those of a medical research worker. Pharmacology has taken a prominent part in the investigation of the ultimate vital phenomena, and it holds out peculiar promise in this direction. Its object and scope go to the very root of the matter. It is the experimental chemistry of protoplasm. As ordinary chemistry studies the properties of elements or of simpler molecules by combining them with reagents, so pharmacology studies the properties of the more complex protoplasm (or biogen) molecules by combining them with similar reagents—in other words, by acting on them with chemical or molecular stimuli. The rich variety of stimuli which pharmacology supplies offers a good chance of solving the riddle of the chemical changes which underly stimulation. This requires, however, a more philosophic comprehension of pharmacology than we have at present. Our science consists as yet for the most part of isolated facts without apparent connection. These must be reduced to general laws. We know, in a general way, that drugs act selectively on certain cells. An intimate connection must exist between the constitution of drugs acting on similar protoplasmic structures, and also between the constitution of structures which are affected by a given drug. These connections are becoming dimly perceptible, but require much detail work in the elaboration of a cellular and comparative pharmacology. The modification produced by reagents must be studied by every conceivable method on vital phenomena in their simplest and in their most specialized forms. They are to be studied in their simplest variety, as exhibited in unicellular structures, as the protozoa; and also in collections of cells—in tissues—where the effects are summed up, and consequently larger, but also more complex. They are to be studied in functions of the most primitive type, as in ameba and bacteria, where the functions are simplest in kind, but are complicated by other functions; and they are to be studied in the most specialized form, as in muscle or nerve, where the functions are single in number, but complex in the development which they have reached. We must also study the corresponding modifications in the constituents of protoplasm, particularly in proteids, in organic and inorganic ferments, in toxins, antitoxins, agglutinins, etc.

As these data become known, it will be possible to connect them, and to arrange them into larger and larger groups. We will then have to inquire into the underlying cause of these groups; in other words, into the principles which determine drug action. It is very probable that the grouping will itself throw light on this question. The selective action of drugs may be in part

explained by selective absorption, in part by chemical affinities of the protoplasm. The explanation of both may be largely the same. In either case there is a co-operation of ordinary physical forces, and of other forces which have not so far been reduced to physical terms, and which are, therefore, called vital. The relations of these two sets of forces are interesting problems which find practical application, e. g., in the phenomena of absorption and secretion. We can not hope to make much advance in the study of these vital forces until the part played by the physical forces is understood. When this has been done, the remaining questions will be clearly and simply stated. It may also be expected that the inquiries necessary for this purpose will throw light on the remaining questions, or will at least point out the way for further inquiry.

These are, in broadest outline, the problems which pharmacology has to solve in the matter. It is needless to say that these ultimate problems may and must be also approached by other channels. The chemist must clear up the constitution of proteids, and eventually of living protoplasm; the morphologist must explain structure, the pathologist the phenomena of degeneration and of death, the physiologist must co-ordinate all these data, etc. Indeed, these problems are the meeting place of all the biologic sciences. To insure any conspicuous success in their solution, the investigator must possess a good measure and quality of "scientific imagination" and an extensive acquaintance with the advanced work in the several departments of natural science; he must have a comprehensive, carefully-matured plan of investigation, in which every achievement of research finds a natural place. Very few can have these qualifications. Nevertheless no investigator can be indifferent to these ultimate problems. Every well-ascertained biologic fact, no matter how isolated or insignificant, will contribute to their solution, for these facts constitute the raw material from which generalizations and laws must be built.

PHARMACOLOGIC RESEARCH FOR THE PROFESSION.

My object in laying before you this outlined program of pharmacologic research has been to show you that pharmacology has very many practical and theoretical problems which are capable of solution, and which are worth solving. A physician who wishes earnestly to co-operate to some extent in this research work, will naturally meet some difficulties, and must be prepared to make some sacrifices. But these will not usually be insuperable. There are problems, on some of which I have touched, which demand little except clinical material and accurate—and especially unprejudiced—observation. Here belongs a great deal of preliminary work in comparing the value of drugs supposed to possess equivalent actions, as also observation of idiosyncrasies, of unusual effects of drugs, etc. I may say here that I consider isolated observations of this kind as usually possessing comparatively small value. They acquire importance only when they are collected and examined critically, collated and generalized. I would suggest that the Chairman of the Section appoint expert committees consisting of clinicians and experimentalists to whom such observations could be communicated and who could report yearly on progress. I have already indicated the rôle which hospitals should have in this work. Sooner or later, the intending investigator will recognize the limitations of such empirical observations, and will desire to apply experimental methods. This requires special training, and usually laboratory facilities. Experimental work is, therefore, best begun in an established pharmacologic laboratory, under the guidance of a skilled teacher. This will offer no great difficulty to those physicians who practice in a medical center. One or two hours every day devoted conscientiously to this purpose will suffice for a great deal of research. For those who live at a distance the difficulties are greater, but can be surmounted by spending a few weeks every year in the city. The sacrifice in doing this is perhaps rather apparent than real. In countries in which the public is educated to realize the value of medical research, work of this kind usually redounds in the end to the advantage of the practice of the investigator. I have not sufficient personal experience to say what would be its effect in this direction in this country. But even if we assume that it does somewhat cut down the income, every physician should ask himself whether it is not worth some cost. On undertaking this work the beginner must take care to make haste slowly. A most frequent cause of failure and disappointment is the choice of problems which are too large or too intricate. If the intending investigator has not had any laboratory training, he will do well to either take a laboratory course, if such can be obtained, or to give what aid he can to a more advanced worker, and to pick up some training in this manner. He may then attack some short and simple problem, intended mainly to familiarize him with research methods. The choice of this he should leave to his instructor. He will thus acquire the experience which will enable him to begin on more independent work, preferably along lines suggested by himself; but he should be slow to dispense with the advice and supervision of some more experienced investigator.

The students of the present generation have considerable advantage over the older practitioners, for some amount of laboratory technic is now taught in all the better medical schools. However, the colleges could do a great deal more in this direction of university work by developing the scientific spirit in their students; through the contagious example of research on the part of the instructors; by offering more extensive and more advanced laboratory courses, and by encouraging original work on the part of students. The luxury of laboring at research can not and should not be forced on every student; but the present medical curriculum is so overburdened that even the most willing student can not find time for advanced university work, and is hard put to it to acquire what is strictly necessary to his calling. The only relief seems to be in some system which cuts down the minimum in all branches, but requires advanced elective work along some lines. Such a system is quite simple and feasible in theory; but in practice it is a most expensive method of teaching, since it necessitates a large staff and costly equipment. However, increase of the cost of teaching is a common condition in all progress of medical education. The endowment of medical colleges is one of the most pressing needs of the day, if they are to keep the pace which they have set.

The efficiency of research work could be very greatly increased by more extensive co-operation and organization. Many questions remain unsolved, many good ideas are lost, many good researches come to naught, for the lack of these. The most important and far-reaching problems are too large to be solved by one man, and must be abandoned or only very partially answered,

unless co-operation of investigators exists. In this sense it would be very desirable if there were some central institute or academy which would direct the activity of all the research workers in a given field; which would assign problems and apportion means; which would direct and co-ordinate the work. The difficulties connected with such a plan are, however, so great that there is little chance of its realization in the near future. Nor is the present system, in which every laboratory is an isolated center of research, without some compensating features. It serves to distribute research over a wide field; it encourages originality, and it is a strong stimulus to competition, which is not always detrimental. These features are not, however, incompatible with some degree of co-operation. Every research worker should place himself in communication with other experimenters, or under their guidance. No better means for this purpose can be imagined than the scientific medical societies, local and national, and their sections. These can, by the appointment of committees, by prescribing of questions and by popular lectures, etc., take on themselves advisory and critical functions which would be extremely valuable, and which would lie strictly within their scope.

This concludes all I wished to say to you on the subject of "Research Problems of Pharmacology." I hoped to convince you that work in this field deserves the active support of the entire medical profession, and that this support is practicable. I have tried to give some suggestions as to the ways in which the best results could be assured. I have also ventured to give my conception of the rôles which the professional pharmacologists and the clinicians, the laboratories, the hospitals, the medical and scientific societies should play in this work. These are deep questions, and the views of others will doubtless be of the greatest value, if the paper is so fortunate as to elicit discussion. The solution to this most direct problem—how much every one of us should contribute to this work—is one which each must necessarily answer for himself.

DISCUSSION

ON THE PAPERS OF DRS. CUSHNY, TYRODE, AND SOLLMANN.*

Dr. Caswell A. Mayo, New York—I am much pleased to have the opportunity to say something on behalf of the American Pharmaceutical Association. That association is working on closely similar lines to those being followed by this Section, a fact which is shown by the character of recent communications read before the American Pharmaceutical Association, one of which was the report of the committee on the acquirement of drug habits, of which committee I am a member. This committee made rather an exhaustive study of the subject by correspondence with members of the pharmaceutic calling, and the conditions found show the great need for radical legislative measures restricting the sale of narcotic drugs. I am happy to say that this need is appreciated, and has already been acted on in Ohio and Illinois. One wholesale druggist in Ohio recently informed me that since the enactment of the anti-cocain law in that state—and the American Pharmaceutical Association is primarily responsible for the passage of the law—his sales of cocain had diminished to one-fourth of what they had been. We know that the sale of cocain in Ohio had grown to enormous proportions, but these sales have been materially cut down, and this is due largely to the activity of the American Pharmaceutical Association and the Ohio Board of Pharmacy. I mention this to show that the pharmacist, though much maligned, still has the good of the public at heart, and fully realizes the obligations under which he rests. No doubt you have seen much in the papers about the amount of adulteration of drugs that is carried on in New York City. Unfortunately, much of this is true, but the manner in which the facts were presented would convey the idea that all pharmacists are guilty of adulteration. All of you know that this is not true and that some of the pharmacists are reliable, and I want to enter a plea with you for the honest pharmacists. Last year the American Pharmaceutical Association celebrated its fiftieth anniversary; this organization was founded for the prevention of adulteration of drugs. This fact shows that the better element in the drug trade is active in its efforts to prevent adulteration, and the physician can help the reputable pharmacist by giving countenance only to those pharmacists who are accurate and trustworthy.

Dr. Henry Beates, Jr., Philadelphia—It is interesting to contemplate what seems to be the natural disappearance of homeopathy. In an effort to establish a law governing practice in the state of Pennsylvania, where there are three boards of medical examiners, a measure was incorporated in the proposed act which would restrict the licentiate to that system of practice representing the school from which he obtained his diploma. In other words, one licensed by the eclectic board would be restricted to eclectic practice, and so, respectively, with the licentiates of the homeopathic and the regular boards. It is interesting to know that a delegation representing homeopathy appeared before the legislature and protested against the incorporation of such an article in the proposed act. In reference to the general results which have been published and taught as the result of investigations on the physiologic action of drugs, and which investigations were conducted by the administration of galenic preparations, it is self-evident that the natural complexity of a given remedy, because of the various active principles possessed, renders these conclusions erroneous. Our physiologic action, therefore, must be practically rewritten, and such conclusions adopted as are based on the exclusive use of chemically-pure active principles. Therapeusis of a scientific character can only be practiced by the use of chemically-pure active principles. The time has arrived when these crude and unavoidably complex galenic preparations must be almost entirely abandoned.

Dr. W. J. Robinson, New York—I am the last person in the world to discourage pharmacologic research. I know the benefits derived from this source have been enormous, but I am not as enthusiastic as I was ten years ago. Ten years ago I was a hearty vivisectionist, and was called all sorts of names by our antis; but I must say that while the benefits are great, we are very apt to be led into error. Our Chairman, in his most excellent address, has shown us that life is neither a chemical, nor a physical, nor a purely mechanical force; but I go still further and say that purely animal life is different in many manifestations from human life. In the former, for instance, suggestion plays no part, while we know what an important rôle it plays on the condition of health or disease in human beings. To mention only two examples which the essayist has given us: He said that experimental research has shown that ether in collapse is not to be used. Clinically, we know that it is a good measure when injected hypodermically. Again, pharmacologic research shows that antiseptics are of no benefit because we can not get a sufficient quantity in the blood to kill the bacteria; still, experimentally, we know that intestinal antiseptics do an immense amount of good. How they do it we do not know, but they do it. I am not opposed to pharmacologic research, but I accept laboratory conclusions with hesitation. In this connection I will read a few words written by Sir William Mitchell Banks, who was at one time an enthusiastic animal experimenter, but whose ideas on the subject have undergone a considerable change. He says:

> No one for a moment will consider me as holding in contempt either experiments or commissions as such, and what I say I say with regret, but my firm conviction is that neither of them has hitherto been of the least avail in aiding us in our search for the best anesthetic or for the best method of using it. There is no possible comparison between a healthy dog or cat or any other animal, and a diseased human being. They are not in the least under the same conditions, and experiments on them are therefore useless. Take on one side a healthy retriever with its heart and arteries all sound, and without knowledge of what is going to happen to it, consequently without the least fear or anxiety. Take, on the other

* The papers of Drs. Cushny and Tyrode appeared last week.

hand, a middle-aged, or somewhat corpulent woman, with flabby heart and somewhat inelastic arteries. Suppose her to be the victim of some cancerous disease the knowledge of which has worn her out with anxiety and distress, and then let her pass a sleepless night before the operation, going over and over in imagination all the terrible process and making sure that she will die under the anesthetic. Or take your drunken, whisky-sodden dock-laborer, with tissues so steeped in drink that one is almost tempted to believe in the possibility of spontaneous combustion, with cirrhotic liver, fatty heart and albuminous urine. I can not see any parallel whatever between the healthy canine animal and the diseased human animal, nor can I see how experiment on the former will help us with the case of the latter. It is impossible.

Dr. Bodine recently reported two cases of chloroform anesthesia, both patients dying before a drop of chloroform had been administered; simply dying from fear or autosuggestion. The conditions in experimented animals and diseased human beings are widely different. Laboratory research should be continued, but we should accept conclusions with the greatest caution, and whenever bedside experience contradicts the laboratory researches we should follow the former, leaving the latter to take care of itself.

DR. W. W. TOMPKINS, Charleston, W. Va.—I would like to see emphasized that part of the address of Dr. Tyrode which speaks of preparations which should not be excluded merely because the kidneys were not doing their duty. There seems to be an impression among the profession that in Bright's disease particularly morphin should be excluded. My personal observation and experience is that morphin will give a certain degree of comfort. So in pneumonia we are told not to use morphin on account of the depressing effects on the heart. I think that all depends on the quantity that is used. Ordinarily, large quantities of morphin, particularly in pneumonia, are injurious; but, on the other hand, one of the most satisfactory means of whipping up a lagging heart is to use morphin in small quantities, such as a sixteenth to an eighth of a grain frequently repeated. Rheumatism is one of the most unsatisfactory diseases we have to deal with. How much effect the salicylates have on rheumatism I am unable to state; in some cases they seem to act like magic, and in other cases they are most disappointing.

DR. M. VEJUX-TYRODE—I agree with the one who said that conclusions should be drawn very carefully from scientific experiments, not only on this subject, but also in scientific experiments on all subjects. As regards the use of ether, its apparent action can be explained. In the first place, all irritating substances have a reflex stimulating action due to the irritation; thus the local application of ammonia, or acetic acid, or cold baths, momentarily increase circulation; but for a longer period of time it is impossible for them to act. Ether depresses the heart only when given in large quantities. There is never greater efficiency of the heart's action, but the vessels relaxed by ether enable you to feel a pulse more plainly, and you have an apparent stimulation which, however, is not real. In regard to experiments on animals and the value of these experiments, I think the criticism is a little too severe. You will find a certain reaction in animals from certain drugs. Of course, we must admit that this varies, but, as a rule, it is only a matter of degree; and, practically, that which stimulates the muscle of the heart does so not only in the dog but in all animals down to the frog. You may say that morphin produces sleep in the higher animal and excitement in the frog. This is explained very easily. There is a certain action of drugs whereby they act strongest on the best-developed functions. In the human being the brain is more highly developed than the spinal cord, therefore morphin brings about sleep, and the stimulating action on the cord is much less manifest because in the higher animal the brain controls the cord more powerfully. On the other hand, in the lower animal the action of morphin is more pronounced on the cord because there is little cerebrum to be acted on, and thus we get excitement instead of sleep. Still, the action of the drug is not changed; it is only a different manifestation in the different animals due to their degree of development. In drawing conclusions for use in disease we must take into consideration all these different actions on different organs. Dr. Robinson stated that when we have two sources of knowledge for the action of a drug, the purely clinical and the pharmacologic point of view, we ought to choose the clinical one. I think that is a point which should be taken into profound consideration before drawing any conclusion, for clinicians have differed widely for ages and ages. A drug will be discarded for a long time and then brought into use again, but for an entirely different affection from that in which it was formerly used, and this shows that the clinical basis for action was not substantial. When sufficient experimentation has been done by reliable men, who all agree on the action of a drug, there should be no hesitancy in leaving the clinical basis and changing to the pharmacologic one.

REMOVAL OF THE FAUCIAL TONSIL;

SOME OBSERVATIONS AND A NEW METHOD OF OPERATION.*

CHARLES M. ROBERTSON, M.A., M.D.
Professor of Diseases of the Nose and Throat, Chicago Policlinic.
CHICAGO.

In reviewing the literature[1] on diseases of the tonsils, it will be found that as early as 10 A. D. the medical men of that age recognized this structure as the seat of disease, for at that time the gland was operated on and completely extirpated. In the work of Celsus (10 A. D.) we find tonsillotomy spoken of as a common practice. It was accomplished either by dissecting with a bistoury or by the fingernail of the operator. Not until much later did the profession become aware of the dangers of the operation, which finally came to be considered dangerous from the fact that cases occurred in which death from hemorrhage followed. It was in the fifth century that medical writers first advocated a modified operation for the relief of enlarged glands in this region. Ætius (490 A. D.) advised the removal of only that part of the gland which protruded beyond the pillars of the fauces. In 750 Paulus Ægineta advised grasping the gland with a tenaculum, drawing it well out of its position and "cutting it out by the root." He limited his operable cases, however, to those in which the tonsils were white and contracted, with a narrow base. He advised against operation on the inflamed tonsil. Albercasis (1120) had the same ideas, showing that the fear of hemorrhage had gained a firm foothold in the minds of medical men of his day.

After this period the operation became obsolete, and in the work of Paré (1509) mention is made of the performance of tracheotomy where there was serious enlargement of the tonsils. He also mentions ligature of the glands, but advised against excision. In 1540 it was suggested to loosen the gland around its edges and then tear it out by grasping it with a vulsellum forceps. As the operation was not easy, and dangerous, great care was enjoined. In 1637, Serverini, during an epidemic of tonsillitis at Naples, removed large portions of the gland, using caustics when they were sessile, a hook and a semi-circular knife when pediculated. In 1672 Dionis advised against operation in any form, as in his opinion the tonsil had a physiologic importance which should not be sacrificed. He did not believe in taking even a small piece away. Many surgeons wrote adversely to the operation. Among these was Heister (1683), who said: "The operation is not only too severe and cruel, but also too difficult in its performance to come into the practice of moderns because of the obscure situation of the tonsils."

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

1. The historic part of this paper was taken from Mackenzie's "Diseases of the Throat and Nose," and the anatomic part from Watson Williams' "Diseases of the Upper Respiratory Tract."

After 1740 the operation with tenaculum and bistoury was again commonly practiced. It was brought again into practice by Meseati and Wiseman. Wiseman first ligated the gland and then cut away the projecting portion. In 1757 Caqué commenced excision again at the Hotel Dieu of Rheims, and proved that the great dread of hemorrhage was unfounded. From this time on the operation became one of the recognized treatments, and instruments began to be improved on and new methods adopted for its performance. The first one to use scissors was Louis, in 1774. He used both straight and curved blades, and at times still resorted to a probe-pointed bistoury. He never cut away more than the inner half of the gland, or that part that projected into the pharynx. In 1827 Physick of Philadelphia caused to be produced the first tonsillotome, which was modeled much after the style of the present Mackenzie. Five years later the first Fahnestock came into use in Germany and France, and was the first ring knife cutting from behind forward. It was practically the Mathieu of to-day. Hundreds of styles are in vogue to-day, till the surgeon has enough to satisfy almost any fancy.

From this early history to the present time we see there have been all sorts of opinions as to the proper method of treatment of this condition, and even to-day there are those who believe the gland should be left discreetly alone.

Historically, we are not much farther advanced than was Celsus at the commencement of the Christian era, and most of us believe, as did he, that diseased glands should be completely extirpated. Surgeons are becoming more impressed with the thought that when necessity demands surgical interference with this gland it should be removed in its entirety. This conclusion has been arrived at after observations made on tonsils which have been partially removed by the tonsillotome. I have observed that, aside from the mechanical obstruction produced, the inner half of the gland is not so detrimental to the health of the patient as the part left *in situ* by the tonsillotome.

In order to bring this subject to your notice in the proper light, it should be stated that tonsils which are diseased may be divided into two classes. First, those which, by their enlarged size, produce mechanical obstruction, thus causing imperfect access both to the stomach for food and to the lungs for air, termed obstructive. And, second, those which do not protrude into the pharynx, or small tonsils, which are diseased and produce injurious effects on the surrounding tissues, or where there occur crypts which constantly fill with secretion, causing foci of infection, called non-obstructive.

In the first instance, a mere reduction of the size of the gland might suffice, whether this be accomplished by excision or the shrinking of the gland. This condition may be relieved by the use of the tonsillotome, and, in the opinion of the writer, is about the only place where the use of this instrument is permissible. With this instrument we are able to remove about two-fifths or one-half of that part of the gland which projects into the pharynx, giving as much room as would be indicated by the inner edge of the palatal arches, it being impossible to get much beyond this. Splitting the tonsil, puncturing it with acids, the use of the galvano-cautery point, or the use of gargles or pigments are of little or no benefit, but all have their devotees, and many think they obtain satisfactory results by the use of such methods. For this we care little at the present time, it being our object to deal with those cases which come under the second class, namely, those tonsils which it is impossible to remove with the tonsillotome, even in part, which constantly fill with secretion in the diseased crypts, and form foci of infection. To this class belong nearly all of the cases brought to the notice of the surgeon. The patient has a history of attacks of tonsillitis, perhaps peritonsillar abscess or "quinsy," and in same cases beginning phthisis. It has been demonstrated beyond question that this gland, when diseased, is a means of infection; it is now classed along with the other infective tracts, the intestinal, respiratory and genito-urinary. It is not hard to believe that these lymphatics are active in the production of disease, if you but observe the great quantities of putrid material squeezed out of a tonsil in the process of extirpation, as it is a decomposing mass, and its retention in the tonsil and surrounding parts permits of its absorption by the system. The part of the gland most productive of this process is found in the supratonsillar fossa. Just at this point let me call your attention to the formation of this gland with its anatomic relations. With the appearance of the horizontal fissures in the lateral foregut there appear the formation of five arches with intervening clefts. From the first arch or plate the lower jaw develops. From the second arch the anterior pillar of the fauces and a portion of the hyoid bone. From the third arch the posterior pillar of the fauces, and the cleft between the second and third forms the fossa of Rosenmueller above and the sinus tonsillaris below. The palate is formed by the ingrowth of the palatal plates from the upper jaw which meet in the median line. These plates extend backward and cross the second and third visceral arches and the intervening cleft, dividing the fetal pharynx into an upper and a lower series of parts.

In the upper part the eustachian tube is developed from the cleft between the first and second arches. Behind it is Rosenmüller's fossa, corresponding to the cleft below the soft palate, which is known as the sinus tonsillaris, in which the tonsil develops, the unoccupied portion of the cleft above the tonsil being the supratonsillar fossa. The faucial tonsil arises by an invagination of the hypoblast in the sinus tonsillaris. The diverticulum thus formed subdivides, forming the crypts around which lymphoid tissue develops. Some authors state that there are often two tonsils formed, but this can easily be understood as being only one tonsil when we reflect that in the formation of the tonsil irregular folding of this diverticulum may occur with the subsequent development, or not, of lymphoid tissue in any particular part. It is thus that the different forms of tonsils occur, and although there may apparently be more than one tonsil, it is one structure which may be subdivided irregularly.

In early fetal life the anterior pillar widens and extends backward, covering the cleft in which the tonsil develops. In this way the tonsil may be more or less completely covered by the thin free border of the anterior pillar, which membrane is known as the plica triangularis or tonsillaris, mentioned further on in this paper. The supratonsillar fossa may extend downward on the outer side of the tonsil between it and the superior constrictor muscle of the pharynx, and also upward and backward into the soft palate. This condition can also be produced by pathologic causes. The supratonsillar fossa appears to be the most important part of the anatomy of these parts from the fact that the uppermost crypts of the tonsils empty into it and because the orifice of com-

munication with the pharynx is often imperfect, owing to the presence of the plica tonsillaris or a hypertrophied condition of the upper part of the tonsil.

The pocket thus formed by the extension of the supratonsillar fossa becomes the receptacle for micro-organisms and the accumulation of decomposing caseous material extruded from the upper tonsillar crypts. The plica tonsillaris is at times very marked, and we can recall cases where a tonsil was almost hidden from view by this membranous fold. A case comes to mind where only a small portion of the superior part of the tonsil was in view through a small round opening six mm. in diameter in the plica tonsillaris. Conditions similar to this are not uncommon. This will easily be understood to close the opening between the supratonsillar fossa and the pharynx and we can readily understand how accumulations in this fossa may be kept penned up, as it were, in a sac. In nearly all these cases we can pass a probe up over the gland into a pocket which varies in size and depth, and at times passes down and around the external surface of the gland. The crypts which empty into this fossa are often pressed on, and if there be a slight amount of inflammation of the pillars, the cavity may be closed off, giving rise to a condition where it is difficult for the secretions to escape into the pharynx. When this exists the imprisoned secretion undergoes decomposition, and an auto-infection occurs. The secretion thus accumulating begins to burrow and gives rise to a condition where the tonsil becomes surrounded with cheesy material, as was described by Pynchon in his article on the "submerged tonsil." I have never seen a case where an operation for removal had been done with the use of the tonsillotome that this top of the tonsil could not be demonstrated. The crypts that empty into the throat are not so apt to fill or stay filled with this secretion as they are squeezed by the pressure made on the tonsil in the act of swallowing by the pharyngeal muscles. For this same reason there is a tendency to form larger pockets behind the tonsil by pressing the secretion toward the point of least resistance. Thus it is common to find cavities extending up into the soft palate and down behind the gland as far as the larynx.

After the formation of such a pocket, even though the supratonsillar fossa becomes communicative with the pharynx again, it is found that there is a habit of secretion becoming lodged here, giving rise to symptoms such as localized tonsillitis, peritonsillar abscess or rheumatism. Owing to the above fact, I have been in the habit of teaching students that if any part of the gland must be left in the throat let it not be the upper portion. In other words, clean out the supratonsillar fossa at all events, for the lower part is of vastly less importance, although we should take that portion also. It makes no difference how small the gland is if it be diseased, for if this perverted secretion is present it should be removed. This secretion has never been studied enough to determine its consistence, but I am wont to believe it is of a cholesteomatous nature.

I have been astonished in finding so many specialists who still adhere to the belief that a diseased tonsil does no harm. I can not understand why it does no harm if we can demonstrate the material it continues to manufacture contains decomposing and septic material and we are able to demonstrate the presence in this secretion of virulent bacilli. I do not wish to be understood as advocating the removal of all tonsils, but that these diseased ones should receive the strictest kind of surgical treatment. It is almost impossible to contend with cases of pharyngitis, tonsillitis, laryngitis and non-suppurative otitis media, unless we get rid of such diseased conditions. This is particularly true of the last-named disease. From the foregoing it is attempted to show that it is not the size of the glands that interests us most, but its character. Thus we may have very large hypertrophies causing little or no trouble, whereas, on the other hand, very small insignificant ones are productive of the direst results.

With these facts in mind it devolves on us to find the best means for the removal of this diseased tissue and the destruction of the pockets already formed. It matters little just how the tonsil is removed, and probably each one of you have a method which is efficacious. Personally, I was in no way satisfied with the means at hand, and have endeavored to perfect an operation at once easy of mode and complete in result. Before describing my own method, however, I should like to state some of the objections I have observed to the means commonly in use:

1. *The Tonsillotome.*—This is figured in the great majority of text-books as *the* way. It seems to me it should no longer be classed as an instrument for complete removal of tonsils, as this is an impossible feat with its use. The only place where its use is permissible is in very young children where the tonsils are so large as to encroach on the process of breathing and swallowing. Even in this case it does the work in a very poor way. It is a compromise and should no longer be tolerated by specialists. The cases of dangerous hemorrhage written about are often after the use of the tonsillotome and occur from the division of a small arterial branch, which on account of its being embedded in fibrous tissue can not retract. The contents of the supratonsillar fossa can never be removed with this instrument, as has been repeatedly shown by clinical demonstrations. It is of no value in small tonsils or those which are long and flat. It, therefore, should be discarded as an instrument for tonsillotomy.

2. *The Snare.*—This method is a good one, but is too slow. The entire gland must be loosened from its attachments above, below, in front and behind, before the instrument can be applied. The hemorrhage may not be so great as by the cutting methods, but cases have come to my knowledge where very severe bleeding occurred. It is a good method where the use of general anesthesia is indicated and especially in children under narcosis.

3. *The Galvano-Cautery.*—Several methods of this type of operative procedure are in use. The method as practiced by Pynchon gives fine results save that it leaves a large cicatricial space on each side of the pharynx. The main objection to this method is the loss of one-half of the anterior pillar and the long period of suffering after each cauterization, and the danger following of middle ear inflammation. As done by its author, one-half of the tonsil is burned out. After this is healed the remaining half is burned away. Then the other tonsil is attacked in a similar way. Each burning leaves the patient with a sore throat for ten days. In this way he must be laid up for forty days for the complete operation, which is an objectionable point, and few patients willingly submit to it. It is not practical at all in children, as each burning occupies from fifteen to twenty-five minutes, and children will not stand this length of performance. Strong solutions of cocain are used, and many people are easily poisoned with this drug.

4. *Dissection.*—This is a tedious operation, requires a good patient and is liable to leave a haggled surface. It is hard to avoid cutting the pillars, and when the tonsil extends well up into the soft palate, as it often does for 2 cm., it becomes difficult. Bleeding is very troublesome, and this makes a clean, smooth wound very hard to accomplish. Hemorrhage is very liable to be severe.

5. *Scissors.*—After trying all the other methods, I have come more and more to depend on the scissors method, and the more I see of them the more confirmed do I become that this method is the best for dealing with hypertrophied and diseased tonsils. After loosening the anterior pillar with a curved bistoury, the scissors are fitted into place, and with two or three snips the tonsil is removed.

After its removal the supratonsillar fossa is explored for fragments, and if any are found it is easy to cut them away. Flat tonsils which extend down to the base of the tongue are as easily removed as little ones. After the tonsil is removed, if any pockets exist they can be cut out in the same manner. The scissors I prefer is one devised by myself and has the following points of advantage: (1) It has blades that can be thrown wide apart with the least possible motion of the handles; (2) as the handles do not have to be widely separated, one is able to operate in a mouth where the teeth can not be thrown wide apart; (3) the curve of the blades is sufficient to avoid the danger of cutting the epiglottis; (4) they are bent on their long axis so that when in position they fit between the pillars of the fauces; (5) they are strong enough to cut through the toughest fibrous tonsil. The instrument used to separate the pillar is a double-edged bistoury curved on the flat and with a dull point. By having it double-edged it may be used to cut up or down and for either tonsil. In its removal the tonsil is grasped by a strong fixation forceps by which the gland is drawn inward. The left tonsil is removed with the scissors held in the right hand, and the right with the scissors in the left hand. It is unnecessary to resort to the use of a mouth gag or tongue depressor. There is little pain after the pillar is loosened and the hemorrhage is not greater than with the use of the tonsillotome. The wound is clean and smooth, and is healed in from four to seven days. The pillars do not attach to each other, and after the surfaces are healed it would be hard to tell that an operation had been done, as very little cicatricial tissue is formed.

After a year's observation, both in clinical and private cases, I am satisfied that this operation is a happy solution of complete excision. In several instances in removing fibrous tonsils I have seen brisk bleeding which in each case was caused by the cutting of a small arterial branch embedded in the fibrous tissue. In these cases I grasp the bleeding vessel with the surrounding tissue and excise it till I find I am into the connective tissue surrounding the tonsil. As soon as this is accomplished the vessel has a chance to retract and the bleeding ceases. I have never had to resort to unnatural means as yet for controlling hemorrhage and have not thus far experienced secondary hemorrhage. Young patients, as well as older ones, are operated on with ease, and it seems to the author that there is nothing wanting to make the operation both generally adopted and useful.

100 State Street.

DISCUSSION.

Dr. Frank W. Hilscher, Spokane—I have been doing a similar operation for about three years, and I am in accord with everything Dr. Robertson said this morning, especially that regarding the removal of those tonsils which ordinarily are not removed. They are diseased tissue and are very frequently the cause of trouble where one would not think they would be large enough to do any danger. Those pockets harbor all kinds of germs, and unless you can get rid of them entirely you have not done for your patient all that you should. I use the scissors usually for the whole operation. I have a certain kind of scissors with which I can remove both tonsils with the right hand.

Dr. S. G. Miner, Detroit—I certainly think that the scissors operation must be performed in a very limited number of cases. The great objection to it is its severity; in private practice the pain and discomfort given the patient is unnecessary except in the diseased submerged variety. I think if more care were taken in freeing the tonsil from all adhesions better results would follow. If that were done in every case the scissors operation would be unnecessary. If we can remove the tonsils with the tonsillotome, it is certainly preferable.

Dr. J. F. Barnhill, Indianapolis—Dr. Robertson's demonstration shows that there are imbedded tonsils that can be well and certainly removed by his method. I have no doubt that if some of us who are less skilled in the use of scissors were to try the operation we would meet some difficulty. I prefer the use of the snare in such cases as Dr. Robertson operated on this morning, first loosening the pillars from the tonsils just as Dr. Robertson did before using his scissors. I think that with the snare method the operator can remove the tonsils much quicker than did the Doctor with his scissors, rapidly though he worked. For a child, I very much prefer the tonsillotome to any other instrument. At this age the gland is soft, not often adherent to the pillars of the fauces, and removal can be accomplished in a very few seconds. This being the case, why should we subject the child to an operation which is longer and more painful?

Dr. E. Fletcher Ingals, Chicago—In the majority of cases that I see, the pillars of the fauces are adherent to the tonsils, and when this is the case I am not able to remove them satisfactorily with the tonsillotome. In adults I use the tonsillotome almost invariably; in children I seldom use it. In children and in adults when the anterior pillar of the fauces is adherent to the tonsil I separate them with the blunt hook and with my finger, and then, with my finger when practicable, dissect the tonsil loose from its bed. It may then be seized with the forceps and removed with the cold snare. In this way there is practically no hemorrhage in the great majority of cases, excepting the little that comes from separating the anterior pillar. I formerly thought there would never be bleeding of any amount, for in hundreds of operations I had not seen it; but one day when operating on a child a vessel a millimeter and a half in diameter bled profusely, but as the patient was under a general anesthetic I had little difficulty in catching the vessel with a hemostat and tying it. In more than 50 per cent. of all cases of hypertrophy of the tonsils in children there is an enlargement at the same time of Luschka's tonsil. If we remove the faucial tonsils but leave a large Luschka's tonsil we have not done our duty. In about 20 per cent. of the cases of adenoids there is also atresia of the posterior nares which should be cured at the same time. Owing to these conditions I place the patient prone with the face drawn over the side of the table and first remove the right tonsil, and then turn the patient to the other side and remove the left tonsil, and with the patient in this latter position I remove Luschka's tonsil. If an operation is done at all it should be done well.

Dr. Robert C. Myles, New York—It would seem that an operation like tonsillotomy should have been more or less perfected before now, but my opinion is that it is in its infancy. For several years I have been experimenting with the tonsils. I have employed the scissors, the guillotine, the snare, and the various forms of tonsil punches, and the operations have been done with and without anesthesia. It seems to me extremely odd that we should think so differently concerning the tonsils. I have never seen a tonsil adherent to the anterior pillars. In the dead room I have taken specimens and given them to the

pathologists and they could not find adhesions. The part some physicians call the pillar is the opercular fold and is a half an inch from the pillar. This fold of mucous membrane touches the pillar only at the upper part. We should determine how much tonsil tissue one is entitled to; we do not know how many cubic millimeters of tonsil tissue should be considered the normal amount. If one examines carefully he will find that tonsil tissue in many cases extends outward into the neck for some distance. In children, on whom guillotine operations on the tonsils have been performed, I often find large masses that should be removed. In the cases in which there is bleeding and vomiting, in a woman, for instance, who is delicate and nervous, the punch forceps is at times preferable.

Dr. H. W. Loeb, St. Louis—In the beginning of my practice I feared and looked for adhesions. I have not found much reason, as Dr. Myles states, to fear adhesions. My trouble is not with the adhesions to the pillars or to the plica tonsillaris but with lateral attachments. When the tonsils extend downward and are attached to the lateral wall of the pharynx you may have considerable trouble. My own methods, of course, have been various. In the more favorable cases, with the electrocautery snare you can get out all the tonsil that projects, and with the cold snare, of course, the same thing could be done. The appearance of the cut surface of the tonsil when the knife operation is used and the rounded appearance when the snare is used, in many cases demonstrates the value of the snare operation in completely removing the diseased tonsillar tissue.

Dr. George L. Richards, Fall River, Mass.—The ordinary Schleich anesthetic tablet dissolved in water and injected into the tonsil will secure an anesthesia that will materially help in operations without general anesthesia. It is of especial value in the snare operation. Dissolved in an adrenalin solution it gives beautiful results in preventing loss of blood. In only one case have I had hemorrhage after this method. I dissolve the tablet in thirty minims of 1 to 6,000 to 1 to 10,000 adrenalin solution.

Dr. Charles M. Robertson, Chicago—We must remember that this is an operation for the removal of the tonsils rather than an operation for the avoidance of pain. The operation is not any more painful than a tonsillotomy ordinarily is. It is not any more painful than the snare operation. It is also not so much a question whether we can get the tonsil out quickly or slowly but rather whether we get it all out. As to the danger of this operation, it seems to me to compare well with other operations. Dr. Ingals says that he never uses the tonsillotome in children but invariably does in adults, and that he never finds adhesions in adults, but does in children. The reverse would seem to me better. In the hysterical man I operated on this morning the adhesions were tough, true adhesions and difficult to cut. In Chicago I have seen many such cases. Of course, what I have called adhesions may be the plica tonsillaris, but there are adhesions there nevertheless. One can use any kind of general anesthesia preferred. The hen-egg tonsils spoken of by Dr. Myles are exactly the ones we are after, and the ones I particularly use my scissors for. The possibility of doing damage to the blood vessels has been suggested. One can go just as far as one needs to get out the tonsillar tissue and no further. After one gets out all the tonsillar tissue one can see the connective tissue. As to the snare, Dr. Loeb's remarks correspond with what I said in my paper. It is a good method, especially in children under general anesthesia. The objection is that you have to loosen up the tonsil too much to adjust the snare. The tonsil often extends up into the soft palate, and you can pull them well down within the grasp of the scissors. These cases make the most beautiful ones for the use of the scissors. The hemorrhage the Doctor spoke of was not a secondary hemorrhage. Secondary hemorrhage comes on later from the sloughing of a vessel. What he mentioned was a late primary hemorrhage. I do not object to the use of the tonsillotome, but it is an imperfect method of operating.

To properly diagnosticate a given case is the *sine qua non.*—*Pennsylvania Medical Journal.*

ARTIFICIAL DILATATION OF THE CERVIX UTERI WITH A NEW INSTRUMENT.

FRANK A. HIGGINS, M.D.
Instructor in Obstetrics, Harvard University Medical School.
BOSTON.

Artificial dilatation of the cervix uteri during labor is a well-recognized obstetric expedient, which is not only of great value in certain cases as a means of accelerating tedious labor, but also becomes an absolutely necessary method of procedure in many instances where the life of the mother or of the child may be dependent on prompt delivery.

The problem of the safe and efficient mechanical dilatation of the rigid cervix of the pregnant uterus is an interesting one which has not as yet been entirely and satisfactorily solved, although there are many methods and a considerable number of instruments devised for the purpose. Under the head of mechanical dilatation of the cervix the writer would include all forms of artificial dilatation whether performed by the hand, by dilating bags, or by instruments.

Bougies and gauze introduced into the uterus, the latter device being known as tamponade of the cervix, should in no respect be regarded as dilators of the cervix, although frequently so considered. These are merely stimulants of uterine contractions in the absence of labor pains.

Manual dilatation, both complete and partial, has doubtless been performed many times by nearly every practitioner of general medicine, and in many cases with the greatest satisfaction with respect to results. In the writer's experience, it has proved of the greatest value as a means of partial dilatation of the rigid cervix in the presence of the tedious and exhausting but inefficient pains of the first stage. For this condition it is best done under primary anesthesia, all that is necessary being accomplished during one or two uterine contractions. The uterine contractions are thereby inhibited for only a few minutes, but the patient is often thus enabled to secure a short period of rest or sleep, which is of material aid to her in completing the labor. The writer has used this expedient a great many times, and has found it much more satisfactory and efficient than the administration of chloral, which is now rarely used. If carefully done, the method will seldom give rise to cervical lacerations.

If the membranes are unruptured, one effort of dilatation under primary anesthesia has always been sufficient in my cases. With ruptured membranes, however, and a rigid cervix, partial manual dilatation finds its greatest value for tedious labor. With a small os, a rigid cervix, ruptured membranes, and the patient becoming worn out from inefficient pains, intermittent manual dilatation, if I may be allowed the use of this term, is better and safer than complete manual dilatation performed at one sitting. That is, partial manual dilatation may be repeated several times, with an interval of an hour or more between, with perfect safety in a dry first stage where the patient is apparently making no progress herself. The intermittent manual dilatation is much safer for the integrity of the cervix than is uninterrupted complete dilatation, and the repeated primary anesthesia at this time amounts to no more than does the giving of ether with single pains in the second stage.

It may sometimes seem that there is no appreciable progress on the part of the patient in the intervals between the dilatations, even with severe pains, and yet

there is in reality progress, and that of an important nature. If carefully looked for, this is shown in the drawing up of the cervix which tends toward its ultimate obliteration or disappearance over and above the fetal head. It is clear, I think, that if complete manual dilatation is performed at one time in such cases, the cervix does not become completely obliterated or taken up in the natural manner, but usually hangs down in the vagina as a sort of border or short curtain around the head. This often gives rise to difficulty in case of a subsequent forceps operation, particularly the anterior portion of the cervix which may obstruct the head. Moreover, I believe this condition is a frequent cause of lacerations to the cervix. As an illustration of this method, recently I gave ether three times and did partial manual dilatation each time in a young primipara with a long and exhausting first stage. This amounted in the end to complete manual dilatation. A high forceps operation was finally necessary, and as a result of so much interference I expected more or less impairment of the cervix, but on examination of the patient four weeks after delivery I was much gratified to find that there was absolutely no tear.

Manual dilatation has, however, always found its widest use in cases calling for rapid dilatation and delivery, and in such is undoubtedly a method of the greatest value. In placenta previa and in eclampsia it is most frequently used.

Complete manual dilatation of the cervix of the pregnant uterus, especially in primiparous cases, is a very exhausting and worrisome procedure, and it not infrequently requires more than an hour to accomplish. It exhausts first one hand and then the other of the operator, and the assistant is often asked to aid because of the severe labor involved. Nothing that I know of in the whole range of surgery is so difficult and so exhausting as the complete manual dilatation of the rigid os, followed by delivery in a primipara at or near term. Moreover, the operation is often unsatisfactory because when it is completed as far as possible, and the closed fist may be inserted and pulled through the cervix, even then the dilatation is not sufficient to admit of the passage of the fetal head at full term, and there is often sufficient delay from this cause to interfere with the birth of a living child. Moreover, after the severe strain and the cramped position of the hands necessary in manual dilatation, the operator is in no condition to perform an operation and to do justice to himself and his patient.

With the various forms of dilating bags I have had a very limited experience. The small fiddle-shaped rubber bags of Barnes were never efficient and are, I believe, practically obsolete, although they still figure in many text-books. The cone-shaped inelastic bag of Champetier de Ribes undoubtedly has certain merits as a dilator of the cervix and also has many warm admirers. It is used more or less extensively as a dilator with ruptured membranes, and also to promote contractions in uterine inertia. Abroad, it is also used in the treatment of placenta previa, where in Dublin, I believe, it finds its chief advocates for this condition. The great objections to its use are that it is often difficult to properly insert; there is danger of its displacing the presenting part at the pelvic inlet; it frequently results in prolapse of the cord, and too violent uterine contractions are likely to be induced.

The use of tents as cervical dilators has, I believe, been almost wholly given up, although they are occasionally advised by writers. Their use is not to be recommended because of the slowness of their action and chiefly because of the impossibility to render them aseptic.

Deep cervical incisions, in place of mechanical dilatation, is a method recently advanced by Dührssen of Berlin, in whom it finds a very strenuous advocate. He is also a great opponent of instrumental dilatation chiefly on the ground of the danger of deep tears, but his opinion can not be considered altogether unprejudiced because of his own operation. Dührssen's method has not been practiced to any great extent in this country or abroad so far as I am aware, outside of his own immediate circle.

That there is a certain considerable and legitimate need and demand for a mechanical dilator of the cervix in pregnancy and in labor is, I believe, plainly evident. This demand is attested by the various instruments which have already been devised for this purpose, although no one of these, except the recent one of Bossi, has ever met with much approval outside of the hands of its inventor.

Considerable controversy has recently been aroused, particularly in Germany, by the introduction of Bossi's dilator, which has had an extensive trial there and in England. Many men have used it successfully and without serious damage to the maternal soft parts. On the other hand, some men denounce it as a dangerous instrument and declare that any form of instrumental dilatation of the cervix is an unsafe procedure. I have myself used the Bossi dilator in two cases of eclampsia demanding rapid delivery, and with the greatest success. Both patients were primiparæ, and in neither was there appreciable laceration. One required nineteen minutes and the other thirty minutes for complete dilatation.

Any contention over the use of methods or of instruments can be settled, I believe, in only one way, and that is by the results of the individual operator. If one finds that by adopting certain methods he obtains better results than by others, then that method is by all means the one for him to pursue. Other observers may get different results and naturally make their deductions accordingly.

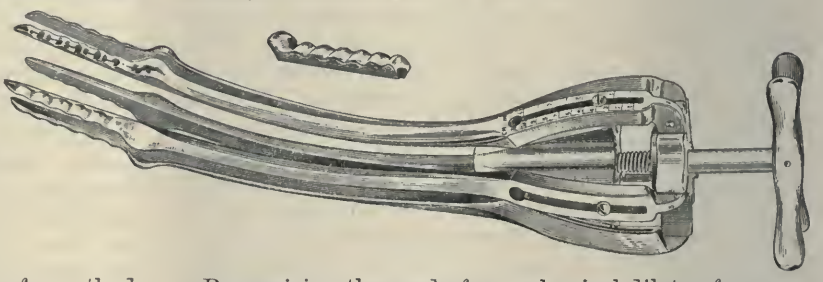
To the average man the operation which accomplishes the result in the easiest manner and with the least damage is the most satisfactory, and that operation, whether it be by hand or by instrument, is the one for him to adopt. There seems to be nowhere any hesitancy in the employment of forcible dilatation of the cervix, but it is altogether a question of how it shall be performed. I have no doubt that forcible instrumental dilatation of the cervix will in some cases, even in the most skillful hands, cause moderate laceration of the cervix, and very likely in unskillful hands occasionally deep tears. Why should this not be so with an instrument? We all know that it does frequently occur with dilatation by the hands, and that dilatation of the cervix without laceration is often impossible of attainment. Can any one describe any method of forcible dilatation which does not give rise to lacerations, or can any one point out any number of cases which have been dilated manually which do not show them?

The deepest laceration I have ever seen—one extending deep into the broad ligament—has recently been under my care for repair, after manual dilatation at the hands of a man who opposes the use of the instrument. I have also known of at least two cases of rupture of the uterus from manual dilatation. Even cases in which

the delivery is entirely taken care of by Nature show deep lacerations. What gynecologist has not seen many deep bilateral lacerations in women who have had absolutely normal labors? There always is, and probably always will be, more or less danger of lacerations in any form of artificial dilatation of the cervix for rapid delivery, no matter whether this is done manually or by instruments. It is practically impossible, in my experience, to dilate a primiparous cervix completely by hand and do a rapid delivery without causing lacerations of the cervix. Undoubtedly, the colpeurynter does this better and with less injury than any other method, but even this is not free from objections on this score.

The danger of tearing the tissues is, I believe, not as great with the metal dilators, if they are used properly and carefully, as it is with the hand attempting to force itself into the closed cervix. With manual dilatation it is often not a question of merely causing tears, but so rigid is the cervix that it becomes largely a question of being able to apply sufficient force to get the os open in some way and of pushing the hand through, regardless of the integrity of the cervix. In many cases where the hand is the agent for dilatation the cervix yields only by tearing.

With the mechanical dilator the force expended can be accurately gauged and uniform power and pressure applied to the cervix, and by keeping the tissues constantly on a moderate tension, letting up a little occasionally to observe its effect on the cervix, the tissues are stretched and give better than by such jerky and irregular force as may be applied under manual dilatation.



I do not wish it to be thought that I believe that manual dilatation of the cervix is to be superseded by instrumental dilatation or even that its field is wider than that of the former. Manual dilatation of the cervix in labor is a procedure of great usefulness, and is considered by many men to be the only safe method, and is the only method used by them. In cases of soft multiparous cervices, in the presence of old tears and in placenta previa, I believe that manual dilatation is usually much better than any form of instrumental dilatation. Indeed, in these cases it is my opinion that instrumental dilatation is usually contraindictated, excepting only certain instances where dilatation of the cervix may be done by some form of the colpeurynter. Instrumental dilatation is best done directly under the eye of the operator who can see and observe the cervix as it dilates and also the extent of each tear as it occurs. With a tear thus easily located, it is a very simple matter, as I have found, to put one or two stitches into the torn edges, although this is rarely necessary.

Granted that instrumental dilatation is permissible in certain cases, I believe it needs no demonstration that a dilator for the pregnant uterus to be efficient must exercise lateral pressure against the inner surface of the cervix. The insertion or pushing of conical-shaped bodies into the cervical canal suffices for slight degrees of dilatations for curettage, but for delivery sufficient dilatation can not be accomplished in that way.

The hand is virtually an instrument of the cone type, and whatever method of manual dilatation is employed the force is essentially that of a cone or wedge. The methods of Edgar and Harris overcome this to a certain degree, but are not applicable to all cases nor is complete dilatation accomplished by these alone.

Bossi of Genoa several years ago brought out his mechanical dilator, although it is only within a year or two that it has attracted much notice. It has proved so far the most efficient instrument yet put before the medical public for rapid dilatation of the cervix. The instrument is of metal with four arms made to expand by means of a series of levers controlled by a single screw. The instrument is undoubtedly a powerful one and able, with the exercise of considerable force, to accomplish the object for which it was designed. The chief criticism to be made of the instrument is that its mechanism is very complicated and it is so put together with its numerous parts, many levers and screws, that it is practically impossible to take it apart for cleaning. This feature renders strict asepsis impossible and is, of course, a *sine qua non* in any surgical instrument at the present time. The instrument, being of metal, may be boiled, but its many slots and crevices will harbor surgical dirt, so that in a very short time mere boiling would be inefficient. It is surprising that this very objectionable feature of the instrument has not elicited criticism before now.

In my opinion, the best feature of Bossi's instrument is that of the removable metal tips, which have been adopted by others, myself included. These admit of an instrument with a small point for use at the beginning of dilatation, while as the os becomes larger and the tips are applied, the pressure is distributed over a broader space so that there is less liability of cutting or tearing the tissues.

Recognizing the need of a mechanical dilator for emergency use I have designed an instrument which I believe will ultimately be found to fulfill every purpose required in an instrument of this kind. It is a five-bladed instrument, the tips of which are made to spread by an advancing cone moved by a screw and a handle. The instrument is made in a thoroughly aseptic manner with a limited number of parts. Each part is easily detached for cleaning purposes and there is no opportunity for the instrument to harbor surgical dirt.

The instrument was first designed for six arms, but I believe five is a better number, for the reason that the pressure is better distributed in five than in six points, no two arms coming directly opposite one another and, therefore, there is less danger from lacerations laterally, where they almost always occur.

Instrumental dilatation is best performed with the patient turned across the bed or on a table in the lithotomy position. A weighted perineum retractor or a broad Sims speculum is used, the anterior lip of the cervix being seized by a double hook and brought into view. The instrument is then inserted without the broad metal tips and dilatation carried to about three centimeters, when the instrument is removed, the tips applied and dilatation completed with them in place. The dilatation should be completed to about four inches by the scale in order to allow sufficient room for the fetal head. A scale in centimeters and inches indicates the amount of dilatation.

The use of the instrument gives one the greatest feeling of security because of the comparative ease with which the work is accomplished directly under the eye of the operator, where the speed may be increased or diminished according to the readiness with which the cervix stretches. A moderate-sized Hanks dilator is sometimes necessary to start the dilatation before the cervix will admit the tips of the instrument, but this is rare in pregnancy. The unopened os can be fully dilated in from twenty to thirty minutes. With the instrument it is not so much a question of how fast the os may be dilated, but, on the contrary, it is altogether a question of how fast the cervix will admit of being stretched, and only so fast should the dilating arms be expanded.

The use of the instrument is indicated mainly when rapid delivery is necessary and chiefly in eclampsia. It should be used only with a rigid cervix. The dilator is also an excellent instrument for the induction of abortion or labor, acting with greater quickness and certainty than any method involving the introduction of a foreign body into the uterus. It will excite contractions in the presence of uterine inertia, and sometimes even when the patient is anesthetized.

In deciding on the propriety of the use of an instrument for rapid dilatation of the cervix one does not have to answer only the question whether or not instrumental dilatation causes lacerations of the cervix. We know that manual dilatation of the cervix frequently does produce extensive lacerations. The question at issue, then, is whether the instrument will generally produce more extensive lacerations than manual dilatation does. This question can not be answered at once, but so far the writer's experience leads him to believe that it does not. In any event, many cases are so difficult of dilatation that the instrument becomes practically a necessity and is a great boon to the operator.

This instrument was devised particularly for use in difficult dilatation in connection with the termination of pregnancy in emergency work. For a number of months, however, the writer has been using his dilator for all purposes of cervix dilatation, and it has been found very efficient for dilatation before curettage. With it wider dilatation of the multiparous cervix can be secured than by any other method, so that in certain cases where it may seem advisable, sufficient dilatation may be obtained to introduce the finger and explore the cavity of the uterus.

THE ETIOLOGY OF YELLOW FEVER.

AN ADDENDUM.*

JAMES CARROLL, M.D.
First Lieutenant and Assistant Surgeon, U. S. Army.
WASHINGTON.

In a paper entitled "The Etiology of Yellow Fever, a Supplemental Note,"[1] the Army Yellow Fever Board (which was then composed of the late Major Walter Reed, surgeon, U. S. Army, and the writer) stated that no results worthy of record had been obtained from the examination of infected mosquitoes, either when dissected in the fresh state or when studied in serial sections after being hardened and embedded. They also reported that two out of three non-immunes had been infected with yellow fever by the subcutaneous injection of 1.5 c.c. of blood serum drawn from a yellow fever patient and subsequently passed through a new Berkefeld filter which was afterward found to be impervious to the *Micrococcus aureus*.

In the latter part of July of the present year there appeared from the Government Printing Office the Report[2] of Working Party No. 1 of the Yellow Fever Institute of the U. S. Public Health and Marine-Hospital Service. These observers (after repeating some of our experiments) presented additional confirmatory evidence in support of the mosquito theory of the transmission of yellow fever and in that respect as well as in the negative results of their blood examinations their conclusions agreed with those of the Army commission. They reported negative results, however, from two (subcutaneous?) inoculations with fresh yellow fever serum after it had been passed through a Berkefeld filter. The quantity of filtered serum injected in these experiments was in one instance one forty-fifth and in the other one-fifth of that used in our own cases.[3]

The most interesting and striking feature of the report was the description of a protozoan parasite to which the name *Myxococcidium stegomyiæ* has been given. This parasite was found with regularity[4] in the appropriate mosquitoes that had bitten patients affected with yellow fever, these mosquitoes after varying periods being killed, sectioned and stained. Simple staining with Bismarck brown or hematoxylin were the methods used by these observers for the demonstration of the parasite. Five forms are described: (*a*) fusiform bodies found in the stomach and ventral diverticulum;[5] (*b*) fragmentation bodies lying in an albuminoid mass within the same diverticulum;[6] (*c*) compact aggregations of spores (called oöcysts) occurring in spherical masses[7] in similar albuminoid material in the same location; (*d*) sporoblasts (?) appearing as single or aggregated spherical or ovoid cells in the albuminous material in the diverticulum and in the tissues of the thorax;[8] (*e*) spores (?) containing sporozoites (?) in the salivary glands.[9] One or more of these stages were said to have been found in a large proportion of the infected mosquitoes that were killed not earlier than the third day after being fed on the blood of patients during the second, third and fourth days of the disease. The cycle of development of these so-called animal parasites as given by the authors is about as follows: On the third or fourth day, after the disappearance of the blood, the stomach was found to contain varying numbers of small fusiform-shaped protozoa arranged singly or in groups and containing a central, oval nucleus. Certain of these forms (budding forms) were interpreted as indicating a terminal conjugation; after conjugation the resulting zygotes migrated through the stomach wall into the diverticulum and underwent further development in a mass of albuminoid material in the latter sac. Here were found also the fragmentation bodies and oöcysts (?), the latter represented by rather compact spherical aggregations of round or ovoid bodies, the sporoblasts (?). After their liberation these sporo-

blasts wandered into the thoracic end of the diverticulum, passed through its wall and the tissues of the thorax until the salivary gland was reached. After penetration of the gland sporozoites were developed and liberated.

Availing myself of the announcement that type specimens were preserved in the collection of the Hygienic Laboratory of the U. S. Public Health and Marine-Hospital Service, I requested permission to examine them, and I desire to acknowledge here the great courtesy and kindness extended to me on two such occasions by Dr. Herman B. Parker, the chairman of the working party. On subsequently re-examining our own sections

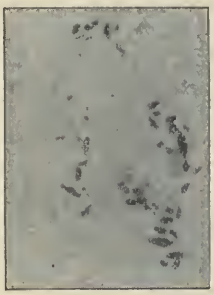

Fig. 1.—This is Figure 15 from the Report of Working Party No. 1, etc., and shows the fusiform bodies found in the stomach and diverticulum of infected mosquitoes.

of infected and non-infected mosquitoes which had already been studied more than two years before in conjunction with my honored colleague, the late Major Walter Reed, surgeon, U. S. Army, and Dr. William M. Gray,[10] microscopist to the Army Medical Museum. I was unable to satisfy myself that a single one of our infected mosquitoes contained any of the fusiform, round or oval bodies described in the report of the working party of the Yellow Fever Institute, but forms

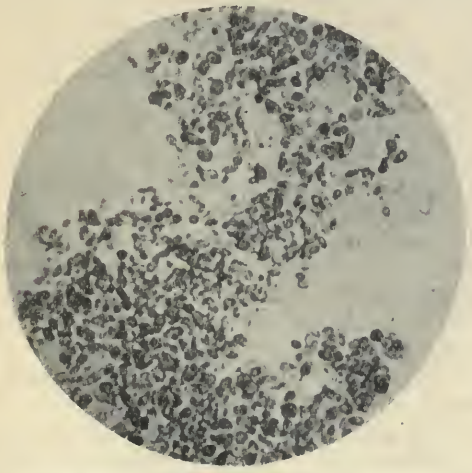

Fig. 2.—Photomicrograph, showing yeast cells in the diverticulum of a non-infected banana-fed insect from Havana. Spherical cells predominate, but fusiform and budding (conjugating?) cells are also shown. ×600.

similar in appearance to those shown in Figure 16 of the report were occasionally found in the stomach contents. From their striking inequality in size and the absence of any structural details in these "fragmentation" forms, I regarded them even in the type specimens above referred to as masses of amorphous granular material. The bodies containing sporozoites[11] (?) which were found in the salivary gland have been abandoned by these investigators because they no longer regard them as of importance.[12] It is noted that in a more recent article by the chairman of the working party all mention of these supposed sporozoites is omitted.[13]

The report does not state in what relative number of insects each of these forms was seen, but I learned from Dr. Parker, on inquiry, that the forms interpreted by

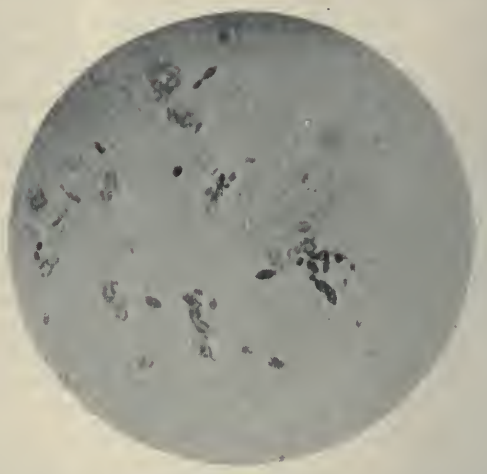

Fig. 3.—Photomicrograph, showing fusiform and budding cells in the diverticulum of another non-infected banana-fed insect from Havana. ×600. These mosquitoes were sectioned and examined early in 1901.

them as fusiform protozoa were the only ones found to be constantly present. These are described as 3 to 4 microns long by 1.5 to 2 microns broad, and containing a nucleus.[14] Appearances interpreted as evidence of conjugation are seen in certain of these forms where two of the ovoid bodies, varying more or less in size, are joined by a slender protoplasmic constriction[15] (see Fig. 1); others show a minute bud projecting from one or both poles. The nucleus appears as a small brightly refractive unstained spot when the bodies are stained with hematoxylin or Bismarck brown, either of which colors the whole cell. The bodies that impressed me as being of the greatest importance, if constantly present, were the

Fig. 4.—Photomicrograph, showing the ellipsoid yeast obtained from banana. Deep colonies in an agar culture two days old. Stained by Gram's method. ×600.

oöcysts (?) in the albuminoid mass[16] and the sporoblasts[17] (?) in the connective tissues of the thorax.

With these pictures fresh in mind, on re-examining our slides prepared from infected mosquitoes, I failed to find any of the forms described, excepting, of course,

10. Practically all of our insects were embedded, cut and mounted by Dr. Gray.
11. Figures 29 and 30 of the report.
12. Dr. Herman B. Parker, chairman of the party, is my authority for this statement.

15. Loc. cit., Figure 15.
16. Figure 23 of the report.
17. Figures 27 and 28 of the report.

the "fragmentation" bodies[18] to which I could attach no significance. On re-examining sections of normal (non-infected) mosquitoes the results were different, for in one of these, cut in cross section, the ventral diverticulum showed large numbers of spherical and fusiform cells, some of them corresponding in size and form to those described by the working party, but stained brilliantly with eosin (see Fig 2). The majority however, were spherical and a few were elongated into large rod forms resembling detached hyphæ. The smallest contained a single refractive spore, of minute size. The larger fusiform or flask-shaped bodies often contained several spores and in a few instances a single spore was seen to have passed into a projecting bud of protoplasm. A few hyphal filaments about 2 to 3 microns broad and 15 to 20 microns long exhibited a central row of spores arranged with a fair degree of regularity. The characters described justified the conclusion that these cells were blastomycetes that had gained access to the body cavities of the insect with food or water.

Fig. 5.—Photomicrograph, showing masses of yeast cells in the stomach and diverticulum of an insect fed on yeast culture and banana. Gram's method and Bismarck brown. Many of the yeast cells are decolorized and stained with Bismarck brown. ×50.

In another non-infected insect cut in longitudinal section, fusiform, ovoid and flask-shaped cells (see Fig 3) corresponding in every way with the fusiform stage of the *Myxococcidium stegomyiæ* as seen in their type specimens, were found throughout the ventral diverticulum, but were present in the upper portion of the stomach only and away from the blood mass. This insect had been permitted to take a meal of normal blood some hours before it died, and it is of interest to note that the organisms were found not within or near the residual mass of ingested blood, but only in the upper third of the stomach and associated with large numbers of bacteria. Their location suggests that instead of migrating through the wall of the stomach to the diverticulum[19] they were carried over mechanically from the diverticulum into the stomach.[20] The large majority of these cells showed a single central refractive vacuole (not spores in this instance) of minute size; a few contained two of them. Hyphal forms were not observed. The sections were stained originally with thionin and eosin on a number of slides and after decolorization the cells described were found also to stain perfectly with hematoxylin, Bismarck brown (these two were the methods used by Parker, Beyer and Pothier). and by Gram's method. Similar results were obtained

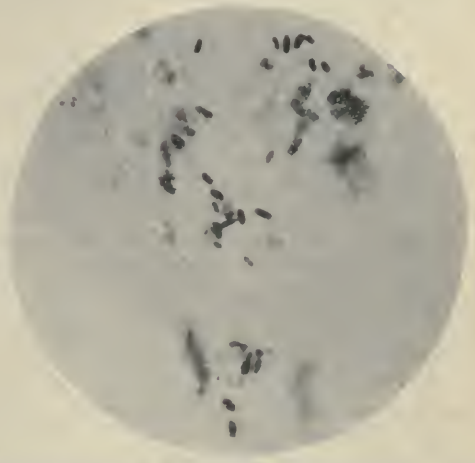

Fig. 6.—The same. A field from the diverticulum. ×600.

with smears from a culture of a white yeast kept in the laboratory. A week or so later I showed these slides to Drs. Parker and Rosenau of the Marine-Hospital Service and expressed the opinion that the fusiform bodies were yeast cells.

In the endeavor to account for the presence of these bodies in our non-infected mosquitoes and their absence from those that had been infected, it was recalled that the insects had been reared and kept in different buildings and fed differently for the greater part of the time at least. The non-infected mosquitoes were supplied

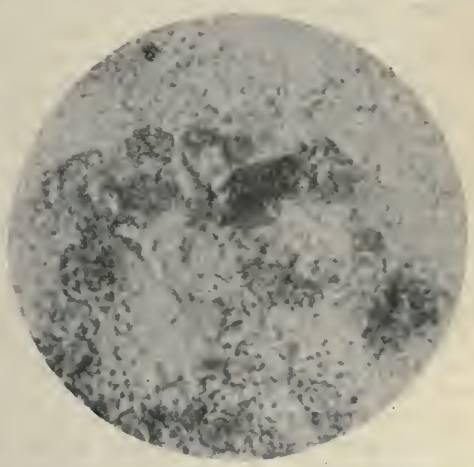

Fig. 7.—Colonies in the albuminoid mass in the diverticulum of a yeast-fed insect. Bismarck brown. ×600.

with banana; the infected insects referred to in this paper were at no time permitted to feed on fruit, but were given only sugar and water in separate vessels. Many of the infected insects were reared under these conditions. I can speak positively on this point, because from the establishment of Camp Lazear until its abandonment the infected mosquitoes kept there were under my exclusive charge and control.

To establish, if possible, the connection between overripe fruits and the presence of these bodies in mosqui-

20. Accompanying the residual food supply, as indicated by Nuttall and Shipley, "Studies in Malaria," Jour. of Hygiene, vol. iii, No. 2. April, 1903.

toes, I obtained some *Stegomyiæ* through the courtesy of Dr. Edmond Souchon of New Orleans and Dr. L. O. Howard of the U. S. Department of Agriculture, the latter kindly supplying me with fifty living insects, a large number of eggs and some insects preserved in alcohol. Fusiform yeast cells were found in the diverticula of a very small proportion of those that were received in alcohol. An ellipsoid wild yeast (see Fig. 4) was then isolated from an old banana and insects were subsequently fed on the fermenting fruit, to which this yeast in pure culture had been added. Previous sterilization of the banana was not considered necessary. As a result, I have brought about the presence of bodies identical in appearance with the fusiform stage of the so-called *Myxococcidium stegomyiæ* in nearly fifty insects that have never been in contact with a case of yellow fever, and have demonstrated them, in large numbers, in the diverticula of four *male* insects that have been hatched and reared in the laboratory of the surgeon-general's office in Washington. I have been able to demonstrate the passage of these organisms from the ventral diverticulum through the natural opening of communication to the esophagus and thence to the stomach, where they are found only in the upper part of the organ, and are absent from the blood mass below, which is of large size and recently ingested. I have obtained in one instance as the result of feeding a male insect on wild yeast and banana, sections which show these organisms among the muscular tissues of the thorax, many of them lying in close proximity to the gland. Several insects similarly treated show the same bodies in the stomach and diverticula. (see Figs. 5, 6 and 7). They have not been found in fifty-two *Stegomyiæ* fed on yellow fever patients and kept under my immediate charge, a number of them having been used in reproducing the disease. Many of these mosquitoes that were kept for inoculation purposes died in the jars and are poorly preserved, but a number were killed and preserved immediately. The state of preservation of the insect, however, does not materially affect the staining properties of the blastomycetes, for in non-infected insects that have died in the jars and are crowded with bacteria, they color brilliantly and sharply. This would seem to indicate that they still retain their vitality after the death of the mosquito containing them.

Dr. L. O. Howard informs me that Dr. J. W. Dupree of Baton Rouge, La., writes him that he also finds the "*Myxococcidium stegomyiæ*" in non-infected mosquitoes at Baton Rouge.

Indirect confirmation of my results is seen in the report cited,[21] where it is stated that the parasite was not found in *Stegomyiæ* that had been applied to a malignant case of malarial fever and were then fed on blood, sugar and water. If a sufficient number of insects had been used and they had been fed on overripe banana or other fruit, as the working party recommends for yellow fever mosquitoes,[22] the supposed animal parasites would in all probability have been demonstrated.

On close examination of the liberated sporoblasts (?) shown in Figures 25 and 26 of the report referred to, it will be seen that these bodies show the variations in size and form and the typical budding process of yeast cells. This is particularly well marked in the left central and lower portions of Figure 26.

21. Report of Working Party No. 1, etc., p. 30.
22. Report of Working Party No. 1, etc., p. 28.

That ellipsoid wild yeasts may be pathogenic for the lower animals is shown by the researches of Rabinowitch,[23] who states also that these cells are stained by all the usual anilin colors. In the course of my own observations it has been found that typical ellipsoid forms in one of the mosquitoes were stained equally well with eosin, Bismarck brown, hematoxylin and by Gram's method.

Similar forms of blastomycetes have already been isolated from the broken-down nodules of spurious glanders, and the statement is made by Italian investigators that several parasites which are classified under the sarco- or micro-spordia belong really to the blastomycetes.[24]

As the yeasts are universally disseminated in Nature (and there are many species of them, only a relatively small number being pathogenic), it is not surprising that experiments with a single species have failed to show positive evidences of invasion of the tissues of the insect. This was obtained by the working party of the Marine-Hospital Service in only a few instances, and is obviously of no importance from the point of view of the etiology of yellow fever. On the other hand, it is regarded as of the greatest importance that bodies identical with the fusiform stage of this supposed protozoön, the only form found to be constantly present, can be easily reproduced anywhere by feeding to mosquitoes a culture of an ellipsoid yeast.

The results of the observations here recorded are believed to justify the following conclusions:

1. The fusiform stage of the so-called *Myxococcidium stegomyiæ* of Parker, Bevor and Pothier (1903), is not connected in any way with the transmission of yellow fever.

2. This organism appears to be not a protozoan parasite, but a yeast fungus. In its fusiform stage, the only form in which it was constantly present, it shows the characteristic budding, staining affinities and vacuolation or spore formation of a blastomycete, and it is found with considerable regularity in both male and female mosquitoes that have purposely been fed on overripe banana to which a pure culture of a wild yeast had been added in the laboratory.

3. The organism has not hitherto been found in repeated examinations of mosquitoes of the genus *Stegomyia* that have bitten yellow fever patients in the early stages of the disease, when such insects had been fed only on blood, dry sugar and water. This statement applies also to mosquitoes that are known to have reproduced the disease in human beings.

HOW TO WRITE A MEDICAL ARTICLE;

A PLEA FOR PLAGIARISM.

G. FRANK LYDSTON, M.D.
CHICAGO.

One of the most galling experiences of the middle period of one's professional career is the discovery that he has been wasting his energies in ambitions which might have been easily gratified by a very modest expenditure of force. How sad the experience of the man who has been for years desperately striving to attain by his pen a certain degree of fame to discover that he has not had discernment sufficient to point out to him the direction of least resistance. How selfish the man who, having learned, alas! too late, the error of his ways, does not give his younger and more un-

sophisticated brethren the benefit of his experience. In endeavoring to aid my professional friends in securing the greatest amount of result from the least expenditure of time and the smallest possible wear and tear of gray matter, I feel that I am sowing seed that, beyond peradventure of doubt, must bear fruit.

The royal road to literary fame is plagiarism, a term which was originally invented for the protection of the hypersensitive feelings of certain giants of the ink bottle, who might have been shocked by the less euphonious term, literary theft. The plagiarist bears the same relation to the thief as does the master of shady business methods. We do not call the latter a thief, we call him a "financier."

The old methods of plagiarism are notoriously faulty. The strained efforts of the old-style plagiarist to be original have resulted in such a distortion of the plagiarized matter that its own father is wont to pass by his literary offspring without recognizing it. Such methods can only be deplored. The estrangement of literary families is cruel. To an author who takes pride in his original creations the sight of one that has passed through the sausage machine of old-fashioned plagiarism is well-nigh insupportable. Full many an author has had his life saddened by this experience.

Time was when plagiarism was sometimes condoned because of its skill and the beauty and value of the finished product as it issued from the plagiarist's mill. Shakespeare even has been accused of plagiarism, perhaps justly, but what a stately edifice was built on the matter plagiarized by the world's greatest master of word architecture. What though Boccacio's literary smut was composed chiefly of thrice-told tales from the Persian—he amplified and beautified them, and added a touch of salacity that required a higher civilization than the ancient Moslem for its production. Longfellow boldly "cribbed" the Kalevala, yet what well-regulated family can dispense with Hiawatha. The example of these shining lights of literature was pernicious, in that it led others into the error of believing that the soul of plagiarism lies in burying its victim a hundred fathoms deep beneath the plagiarist's own verbiage, it being, however, unnecessary to add to the value of the original production by a flavor of original thought. Out of the use and abuse of the good fairy, Plagiary, there has evolved a new school of plagiarists whom to know is to admire. The chief tenet of this new school is that plagiarism should be so conscientiously perpetuated that the most captious author can not accuse the plagiarist of mutilating his work nor of distorting the original matter. Still less could the rightful author fail to recognize his own. The new school has also exploded the fallacy that the quotation mark is a necessary feature of composition.

Strange to say, the new school is not without detractors. Indeed, I should have probably not felt compelled to rise in defense of the modern idea of plagiarism had it not been for one of these detractors, who saw fit to write me a letter calling attention to some of my stuff that had been recently presented in a new and attractive form by a distinguished exponent of the art of modern plagiarism. The letter reads as follows:

MIDWAY, PA., Oct. 11, 1903.

DR. G. FRANK LYDSTON, Chicago, Ill.

Dear Doctor:—Enclosed you will find an example of flagrant plagiarism. I believe the good of the profession demands the exposure of such men.

The article referred to was torn, unfortunately, from some medical journal whose title was not noted; but you can easily trace the article. It was published within the last four months. It is taken bodily from your article on "Gonorrhea in Women," published in your "Addresses and Essays."

I hope to learn that you have traced the article and required the editor to publish the facts. Respectfully yours, etc.,

A. L. RUSSELL, M.D.

The paper to which Dr. Russell alludes is entitled:

THE REMOTE EFFECTS OF GONORRHEA IN THE FEMALE.

BY W. E. FITCH, M.D.

Member American Medical Association, American Editor's Association, Medical Association of Georgia, Medical Society of the State of North Carolina, Chatham County Medical Association: formerly Editor *Georgia Journal of Medicine and Surgery.*

SAVANNAH, GA.

The article was read at the last meeting of the Georgia State Medical Society, and appeared in the *Annals of Gynecology and Pediatry,* September, 1903.

I have rarely been so pained as by the perusal of Dr. Russell's letter. I had considered him one of the discerning ones: his letter proves me in error. I trust he will not be offended at my taking him to task. In the first place, my correspondent is in error as to the work from which the marrow of Dr. Fitch's article was taken. It was chiefly my text-book on "Genito-Urinary Diseases," published in 1899, that gave him his subject-matter, as witness the new terminology which has come in vogue since my collection of essays and addresses was published, in 1892. It could not have been taken from my work on gonorrhea, published in 1892 (Davis' Leisure Library series), because of a similar slight lack of correspondence in the language, although the ideas were the same. As the essay alluded to by Dr. Russell was published eleven years ago and was a pioneer contribution to the subject, the assertion that Dr. Fitch's article was taken from it is by no means flattering to that gentleman. If the assertion were true and Dr. Fitch had slept a few years more, he would have given us a medical Rip Van Winkle.

No, my dear Dr. Russell, you must not allow your prejudices to blind you to the fact that Dr. Fitch is thoroughly up to date. He was manifestly fair to me primarily, for, save the first paragraph, he copied his article from my latest production on the subject.

There is one feature of Dr. Fitch's work that even so captious a critic as Dr. Russell must admire, viz., the accuracy of the copy. I was greatly delighted to find that even the style had not been impaired. Not that I plume myself particularly on my style, but it is nice to be able to recognize one's own children. They may be strabismic, carroty-haired, and lopsided, still they are one's own and ink is thicker than water.

As for the verbiage of the copy, it varies from the original only to the latter's advantage. It will be further noted that Dr. Fitch is consistent throughout. He launches boldly into his appropriation, demonstrates his unerring accuracy—for which the editorial habit must be thanked—and sustains the standard he has set for himself for pages and pages.

A comparison of the parallel columns will prove my point.

DR. LYDSTON'S TEXT-BOOK.	DR. FITCH'S ARTICLE.
Gonorrhea in the female as now understood is more often met with in the special field of gynecology than in that of venereal diseases. This would seem, *a priori,* a trifle paradoxic, yet if the more advanced views be correct, the correlatives of gonorrhea and gleet in the male are too frequently regarded as simple and non-venereal in the female. Then, too, the more serious results of gonorrhea in women are at the present time relegated to abdominal surgery; a field that the gynecologist would fain monopolize. A knowledge of these conditions in their various phases, and a just appreciation of their relation to venereal infection, are nevertheless absolutely indispensable to the genito-urinary surgeon.	Gonorrhea in the female, as now understood, is most generally found in the practice of the gynecologist, rather than in the work of the specialist in venereal diseases. This would seem, *a priori,* a trifle paradoxic, yet if the more advanced views be correct, the correlatives of gonorrhea and gleet in the male are too frequently regarded as simple and non-venereal in the female.

In my earlier papers on the subject, "Essays and Addresses," 1892, and "Monograph on Gonorrhea," 1892, the construction of the foregoing paragraph was as follows:

Gonorrhea in the female is perhaps more often met with in the field of labor of the gynecologist than in that of the venereal specialist. This would seem from *a priori* consideration a trifle paradoxical, etc.

Dr. Fitch has done me the honor of appropriating the first few lines of this.

DR. LYDSTON'S TEXT-BOOK.	DR. FITCH'S ARTICLE.
The special consideration of the effects of gonorrheal infection upon the female sexual organs is of great practical value, the more especially as the *matrics morbi* of the disease is primarily generated in women. It is a striking clinical fact that gonorrheal inflammation in the female rarely presents con-	The special consideration of the effects of gonorrheal infection upon the female sexual organs is of great practical value, the more especially as the *matrics morbi* of the disease is primarily generated in woman. It is a striking clinical fact that gonorrheal inflammation in the female rarely presents consid-

ditions physically analogous to those observed in the male. Vaginitis of venereal origin is exceptional, and urethritis, the only real analogue, is excessively rare in women, and, moreover, does not always occur when virulent vaginitis exists. The rarity of virulent vaginitis, even in that numerous class of unfortunates from whom the male acquires the disease, is only explicable by: 1. The existence of latent gonorrheal processes of a greater or less degree of virulency in the female. 2. The gradual acclimation of the vaginal mucous membrane to the toxic products of organic decomposition slowly formed in the female generative apparatus. If it be accepted that the urethra of the male may become acclimated to morbid conditions existing in the female, as is often seen in the husbands of women who are infectious to any strange male with whom they may sustain sexual relations, it must also be accepted that the vagina becomes inured to contact of the irritating products of morbid conditions of the mucous membrane higher up: i. e., becomes tolerant of autogenetic poisons. This same tolerance explains the resistance of such women to the disease when they are exposed to contagion. 3. The relatively inherent toughness of the vagina, as a consequence of which it may serve as a vessel in which toxic materials can be elaborated without itself becoming infected by them. This inherent resistancy does not extend to the endometrium—cervical or corporeal—Fallopian tubes, and peritoneum; hence women may be affected by more or less active gonorrheal processes in these parts while the vagina is apparently healthy.

erations physically analogous to those observed in the male. Vaginitis of venereal origin is exceptional, and urethritis, the only real analogue, is excessively rare in women, and, moreover, does not always occur when virulent vaginitis exists. The rarity of virulent vaginitis, even in the *demimonde*, and that numerous class of unfortunates from whom the male acquires the disease is only explicable by: First, the existence of a latent gonorrheal process of a greater or less degree of virulency in the female; second, the gradual acclimation of the vaginal mucous membrane to the toxic products of organic decomposition slowly formed in the female generative apparatus. If it be accepted that the urethra of the male may become acclimated to morbid conditions existing in the female, as is often seen in the husbands of women who are infectious to any strange male with whom they sustain sexual contact, it must also be accepted that the vagina becomes inured to the irritating products of morbid conditions, of the mucous membrane higher up: i. e., becomes tolerant of autogenetic poisons. This same tolerance explains the resistance of such women to the disease when they are exposed to contagion.

The relative inherent toughness of the vagina, as a consequence of which it may serve as a vessel where the toxic materials can be elaborated without itself becoming infected by them. This inherent resistancy does not exist in the endometrium, cervical or corporeal, Fallopian tubes, and peritoneum; hence women may be affected by more or less active gonorrheal processes in these parts while the vagina is apparently healthy.

[A long paragraph is here omitted to save space, being practically the same in both columns.—ED.]

Noeggerath's theory as originally formulated implies: 1. That nearly all individuals who have at a more or less remote period contracted gonorrhea and have apparently been cured are capable of imparting infection to the female. Thus, most men who have ever had the disease, according to Noeggerath, sooner or later infect their wives.

2. That this infectiousness on the part of the male is in many cases latent, but may possibly become perceptible by the occurrence of urethritis of greater or less degree of severity, as a consequence of sexual intercourse.

3. That consequent upon this latent condition of gonorrhea in the male there occurs a similar latent infection of the wives of those affected.

4. That the majority of women who marry men who have at one time or another had gonorrhea, become sooner or later the subjects of uterine and pelvic inflammations.

Noeggerath's theory as originally advanced teaches:

That nearly all individuals (men) have at a more or less remote period of their lives contracted gonorrhea; have apparently been cured, but are still capable of imparting infection to the female.

That this infectiousness on the part of the male is in many instances latent, but may possibly become perceptible by the occurrence of a urethritis of a greater or less severity, as a consequence of sexual intercourse.

That consequent upon this latent condition of gonorrhea in the male there occurs a similar latent infection in the wives of husbands thus affected. . . . .

[Another long paragraph is here omitted from each column, being practically the same in each.—ED.]

With regard to the frequency of gonorrhea among the inhabitants of cities, Noeggerath said some years ago: "I do not know what the state of matters in other cities is; I did not know how we stood in New York until I questioned the husband of every woman who came under treatment; but I believe we may apply here the dictum of Ricord, that 800 men in 1,000 have had gonorrhea." He goes further and says: "I believe that I do not exaggerate when I say that gonorrhea in 90 per cent. of cases remains uncured. Of every 100 women who have married men formerly afflicted with gonorrhea, hardly ten remain well, the others are afflicted by some of the ailments which I have attempted to describe."

Making due allowance for the possibility of statistic errors and exaggerations in the original assertions of Noeggerath, it must still be admitted that gonorrheal infection may cause any or all of a series of disastrous results in the female pelvic organs. Thus, metritis, endometritis, salpingitis, hydrosalpinx, pyosalpinx, ovaritis, parametritis, pelvic peritonitis, menstrual disorders and sterility may occur, according to the age and severity of the process and the character of the structures affected. . . .

Dr. G. Frank Lydson, in writing on this subject, says: "Eight hundred men in one thousand have had gonorrhea." He further states that 90 per cent. of cases remain uncured. This coincides, though a little conservative, with another prominent writer's views, who makes the statement, "Once a gonorrheic always a gonorrheic."

Of every hundred women who have married men formerly affected by gonorrhea, hardly ten remain well, the others are afflicted by some of the ailments which I have attempted to describe.

Making due allowance for statistic errors and exaggerations in the original researches of Noeggerath and other workers in this field, it must still be admitted that gonorrheal infection may cause any or all of a series of disastrous results in the female pelvic organs, viz., metritis, endometritis, salpingitis, menstrual disorders and sterility may occur, according to the age and severity of the process and the character of the structures affected. . . .

[Another paragraph is here omitted, being practically the same in each column. There is also omitted from each column some paragraphs which do not appear in the other and are therefore immaterial.—ED.]

The disease is normally self-limited, and if complications can be prevented, not only is recovery likely to be secured within a reasonable period, but prolonged infectiousness may be averted. The higher the process extends the more prolonged and insidious will be the infection. The chief aim of the surgeon should therefore be the prevention of the extension of infectious inflammation. Rest is the best means of accomplishing this, sexual rest, especially be quite as important in this respect as in the male when similarly infected. Vaginal douches of potassium permanganate, 1 to 2000 to 1 to 1000 are a *sine qua non*. . . . Mercury bichlorid and silver nitrate are valuable, but by no means to be compared with the permanganate, which is the nearest approach to a specific at our command.

Urethritis and vesical complications demand balsams and alkalies internally, with the permanganate irrigations. Later on silver nitrate irrigations may be substituted with advantage. Instillations of permanganate or silver solution with a syringe may be useful, especially when the process shows a tendency to become chronic.

Anodynes and sedatives may be indicated in some cases, especially if complications occur or sexual irritation be marked.

The disease is normally self-limited, and if complications can be prevented, not only is recovery likely to be secured within a reasonable period, but prolonged infection may be prevented. The chief aim of the physician should be to prevent the extension of infectious inflammation. Rest is the best means of accomplishing this, sexual rest especially is of the greatest importance. Vaginal douches of permanganate of potassium, 1 to 2000, or 1 to 1000, are indispensable. Mercury bichlorid and silver nitrate are valuable, but not so trustworthy as permanganate of potassium.

Urethritis and vesical complications demand balsams and alkalies with the permanganate irrigations Anodynes and sedatives may be indicated in some cases, especially if complications occur or sexual irritation be marked. If much pain and a frequent desire to void urine exist, urinary antiseptics and vegetable diuretics, as corn silk, triticum repens, etc., will give speedy relief. . . .

In the first paragraph of the parallel columns it will be noted that Dr. Fitch has substituted the word "practice" for "field of labor," and "specialist in venereal diseases" for "venereal specialist." The implied adverse criticism of my verbiage is accepted in the same spirit in which it is given. The delicate compliment to the specialist in venereal diseases implied in the intimation that Dr. Fitch does not consider him "venereal" is worthy of a Chesterfield.

The insertion of the word "*demimonde*" in the second paragraph shows a literary finish to which Dumas himself, the coiner of the word, were he living, could not take exception. The word lightens up the gloom of the otherwise turgid and heavy style for which I am noted, and illumines the pages with a brilliant forecast of future improvement in my composition for which I shall never cease to thank my confrère. I use the word confrère advisedly, not to be outdone in generosity, for I am sure my learned friend could ill spare the word *demimonde*, and I, therefore, reciprocate from my own scanty store of "furrin things."

Dr. Fitch has really gone out of his way to be generous to me. He has given me credit for views which I quoted from Noeggerath. There may be those who will suspect Dr. Fitch of a lack of good faith. He has misspelled my name, and, considering his accuracy as a copyist, that is a bit suspicious.

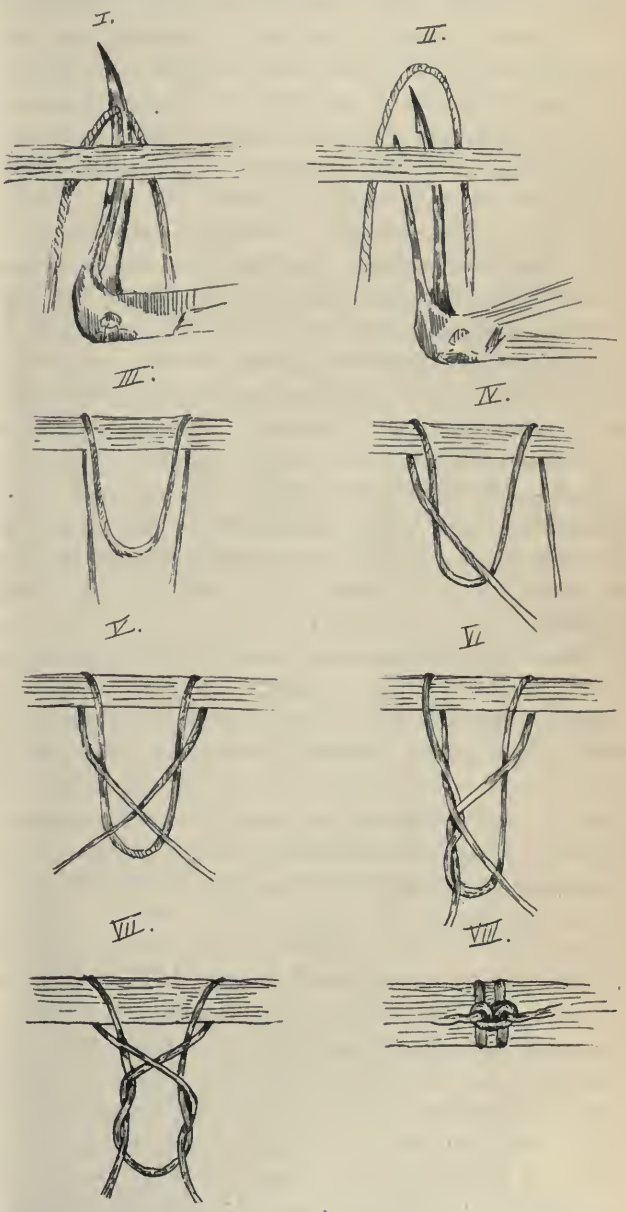
That Dr. Fitch is impartial is shown by the fact that he has appropriated a paragraph of Noeggerath's stuff. Perhaps this was to temper my self-conceit. I confess it was somewhat of a dampener to find that Noeggerath's verbiage was so essential a part of my original text that it could not be copied without it.

I was especially pleased to note that Dr. Fitch has quoted Bumm (Bumm is spelled "Burum," and Veit's "Handbuch" is presented as "Voit's") on the evolution of the gonococcus. Had he been alive to the possibilities, however, he could have found some ideas on this subject also in my text-book. He might have used these ideas as original matter, especially as my first papers on the subject were published about fifteen years ago, and appeared in my text-book four years ago. It would have been safe to use them, for they did not have a foreign label, and the American profession would have given such scant credit as it usually accords to home-raised ideas to Dr. Fitch. Taken all in all, Dr. Fitch's article is a most accurate presentation of the views and language expressed in my text-book. His conservatism in the matter of reconstruction of language is admirable. If his editorial training is responsible for his accuracy and conservatism, would that all editors used the same ink. The wisdom of conservatism as displayed by Dr. Fitch is especially evident if one considers how important it is not to garble another's statements on a scientific subject. Wisdom, accuracy, delicacy, good taste and—I was about to say, literary finish, but modesty forbids—what more would the critic have?

It occurs to me in passing that Dr. Fitch may have been actuated in part by the notion that I was dead. If so, his desire to perpetuate my work by putting it forth in such form as to be unmistakably mine, is highly commendable. He must, however, be more wary of accepting as authoritative rumors based on that fraternal wish which is father to the thought and a fungus on the sturdy old oak, competition. Prognoses given as a matter of professional courtesy and esteem are sometimes unreliable, not to say disappointing. It will, of course, be understood that I can not undertake to discuss Dr. Fitch's article. I can not attack it, because I have not yet changed the views expressed in the book from which the bulk of the article was taken. I can not particularly commend its scientific merits, lest I be accused of crass egotism.

If the easy road to medical writing pointed out in this article proves of value to any struggling aspirants for literary and scientific fame, I shall be well rewarded. If all who in the future copy the work of others are stimulated to emulate Dr. Fitch's example and copy so conscientiously that no quotation marks or allusion to the rightful author are necessary, medical literature will owe me much. My chief hope is that this communication may be incorporated in the history of American medicine as a clinical contribution to the study of —well, hypertrophy of literary gall.

New Appliance.



A SIMPLE AND EFFECTIVE KNOT.

H. L. NAHIN, M.D.
MILWAUKEE, WIS.

In tying the ovarian or uterine artery or any part of the broad ligament, the danger of secondary hemorrhage is always great. It is chiefly due to some defect in ligating the pedicle. The first loop formed in the reef or surgeon's knot is usually disturbed and loosened the minute the pressure of the surgeon's fingers is removed; while making the turn of the second loop the ends are made tense and the first loop is pulled up and consequently relaxed.

To overcome this difficulty I devised a knot which is simple in execution and safe in its not getting relaxed or loosened after it is secured in place, and which, if placed two centimeters from the cut end, will never slip off.

In tying the ovarian artery for instance, a loop of a double ligature is passed with the ligature carrier through the clear space in the broad ligament from before backward, as shown in Fig. 1; the loop is then released from the ligature carrier, as shown in Fig. 2; it is then brought forward by the assistant over the top of the broad ligament, as shown in Fig. 3; the free ends of the ligature are now separated by the surgeon holding the right end in the right hand and the left end in the left hand; he now crosses the left free end of the ligature to the right over and above the loop as shown in Fig. 4. Then he crosses in the same manner the right end of the ligature to the left over the loop as shown in Fig. 5. Now the free right end of the ligature is in the left hand, and the left end in the right hand *over the loop*. The surgeon now carries the right end of the ligature around behind the loop and forward *through* the loop to the left border of the inside of the loop, as shown in Fig. 6, and the left end in the same manner to the right border of the inside of the loop as shown in Fig. 7. The ends are now pulled snugly, separated, and with the ends of the index fingers pulled and at the same time pressed on the knot. An additional reef knot may be applied over this knot, but it can be dispensed with, as this knot is firmly interlocked and any

pressure or pulling up, down or sideways tends to bring the interlocked fibers of the ligature more snugly together.

Fig. 8 shows the knot complete after it is tied.

The same knot can be utilized with ease and safety when the broad ligament is to be ligated in sections. In such cases all it is necessary to do is first to bring out the loop with the ligature carrier, which is given to the assistant; then the free ends of the ligature are carried through another point embracing all the structures to be ligated, and the same procedure is followed as in the first description.

ACUTE PANCREATITIS.

The acute inflammations in the pancreas have been generally recognized as the source of trouble in the upper part of the abdomen only in very recent years, practically all important contributions on this subject having appeared since the publication of the lecture on this subject by Fitz of Boston in 1889. Interest in this affection has been specially stimulated since recent experimental studies have so definitely shown the connection between fat necrosis and pancreatic disease, for until this was recognized, fat necrosis was considered by many a distinct disease, instead of a pathognomonic symptom of pancreatitis. The evidence of association between gallstones and pancreatitis so clearly shown by Opie's observations, added another important reason for early operation in gallstone diseases, and attracted widespread attention, so that at present few surgeons would overlook the possibility of acute pancreatitis in any case in which acute symptoms were localized in the upper abdomen.

Most recent writers agree that the clinical picture is characteristic enough to make a probable diagnosis of acute pancreatitis quite within the range of possibility. The intense, colicky, epigastric pain which later becomes general; the intractable vomiting; the abdominal distention, particularly above the umbilicus; the tenderness and rigidity together with marked collapse, small and rapid pulse and often cyanosis are mentioned by all. The diagnosis is still more probable if this group of symptoms occur in a middle-aged man who is corpulent and has gastro-intestinal catarrh, arteriosclerosis or a history of alcoholism, gallstones or injury. The differential diagnosis, then, lies between pancreatitis and the other causes of acute abdominal symptoms in this region, as intestinal obstruction; perforating ulcer of the stomach or duodenum; ruptured gall-bladder or bile ducts, a phlegmonous cholecystitis and a gangrenous appendicitis; a positive diagnosis is generally admitted to be very difficult if not impossible in most cases.

With regard to the desirability of surgical treatment and the time at which it is best undertaken, there are wide differences of opinion. Some advocate immediate operation, others advise waiting until collapse passes off, while some even advocate waiting until a local abscess forms. Bearing on the question of treatment two recent papers are of considerable importance. Woolsey[1] reports three cases, all quite ill at the time of operation, but all of whom recovered after simple evacuation of a considerable quantity of fluid from the peritoneal cavity and drainage. Pels-Leusden[2] also reports three cases operated on in practically the same manner, with recovery of two and temporary improvement in the third case. Two of the patients were practically moribund at the time of operation, but improvement was immediate in all the cases after simple evacuation of the large accumulation of exudate and drainage. Both of these writers advocate early evacuation of the peritoneal fluid and the contained septic material and drainage. A small medium incision under cocain anesthesia is all that is necessary, and more extensive exploration is to be avoided in a patient in such a collapsed condition. Early operation, sometimes under cocain, is also recommended by Robson and Moynihan,[3] and was advocated by Hahn, who operated successfully in a case similar to those reported.

Unfortunately, a large proportion of patients who suffer from the severer forms of acute pancreatitis will die whatever method of treatment is adopted, but we believe that the early and simple operative procedure recommended above is the rational method to follow in these cases, for undoubtedly, as Woolsey says, a large percentage of the patients will die in waiting for a more favorable time for operation, just as would be the case if we were to wait to drain an appendix abscess rather than to take the disease in its early acute stage. Moreover, practically all agree as to the impossibility of making a positive diagnosis between acute pancreatitis and several other acute abdominal affections, all of which demand immediate operation if the life of the patient is to be saved. Quite probably the percentage of recoveries will be greater when such prompt and simple operative intervention is adopted as in the cases reported above.

THE SIGNIFICANCE OF INFECTION, HEREDITY AND PREDISPOSITION IN THE DEVELOPMENT OF PULMONARY TUBERCULOSIS.

It is a well-known fact that pulmonary tuberculosis is more common among the poor, the careless, the ignorant and the depraved in a community than among those belonging to the opposite class. It is likewise an authenticated observation that the disease seems to exhibit a predilection for certain houses, or rather that a disproportionate number of cases occur in such houses. The natural inference is, therefore, that special opportunities for transmission exist under such conditions, but a question has been raised as to the part played in this connection by heredity and predisposition. It has, for example, been noted that not all persons equally exposed are attacked; that certain families especially suffer, and that women are often the victims of the disease in connection with the puerperal state and lactation.

Some observations have been made into the questions at issue, but they have principally related only to tuberculous patients. Accordingly, Dr. E. Schwarzkopf[1] studied 354 female patients over 13 years of age—160 with and 194 without pulmonary tuberculosis—presenting themselves at the medical clinic of the University of Marburg. Men and children were excluded because of the etiologic significance of occupation, change in residence and association with large numbers of persons in the former and the relative rarity and often the difficulty of recognition of the disease in the latter, while the conditions referable to the women could be better noted and controlled. Only cases were considered in which the diagnosis was clear, merely suspicious cases being rejected.

Of the total number, 145—40.96 per cent.—had been exposed to infection by association with tuberculous patients, sometimes for years, while in 209—59.03 per cent.—no such exposure could be made out. Of the women that had demonstrably associated with tuberculous patients, 98—67.58 per cent.—became affected with pulmonary tuberculosis, and 47—32.41 per cent.—remained well. Of those that had not associated with tuberculous patients, 62—29.66 per cent.—became tuberculous, and 147—70.33 per cent.—remained well. Of the tuberculous patients, 98—61.25 per cent.—had demonstrably associated with tuberculous patients, and of the non-tuberculous patients, 47—24.22 per cent. Those that had lived together with several tuberculous patients, at once or in succession, suffered in larger number than those that had been exposed to but a single source of infection. The danger of such association was found to be the greatest between the fourteenth and the fortieth year. Infection during childhood was responsible with comparative rarity for pulmonary tuberculosis developing after the thirteenth year.

The evidence of hereditary acquisition was, according to Schwarzkopf's findings, no greater in tuberculous patients than in non-tuberculous patients. In fact, he claims, it was actually a little greater in the latter than in the former. The greater danger from the mother than the father is due to the fact that the former is more in the house, and thus is a more prolific source of infection. Of pregnant, parturient and nursing women, while the number exposed to infection was the greater, as compared with those not so exposed, the difference was not so marked as with respect to other influences.

The results of these observations are summed up by him as follows: In the development of manifest tuberculosis of the lungs, infection with tubercle bacilli, such as is brought about by association with uncleanly tuberculous patients under unfavorable external conditions, plays an important part. In women suffering from tuberculosis antecedent, opportunity for infection could be demonstrated in 61.25 per cent. of the cases, and in only 24.22 of non-tuberculous women. Almost every person—at least in the unfavorably situated portion of the community—is afforded opportunity for the taking up of isolated tubercle bacilli. In order, however, that pulmonary tuberculosis may develop repeated infection is necessary in the majority of cases. The danger of acquiring tuberculosis increases with the number of patients in the vicinity and with the duration of the opportunity for infection. Infection in childhood gives rise with relative rarity to pulmonary tuberculosis developing after the thirteenth year of life. This takes place much more frequently if renewed infection occurs. The taking up of tubercle bacilli in the period between the fourteenth and the fortieth year of life is particularly dangerous, and the danger increases up to about the age of forty years. The danger of a tuberculous patient to those by whom he is surrounded disappears when the patient observes suitable precautions with respect to coughing and expectorating. Schwarzkopf holds that mere hereditary predisposition has not the slightest influence on the development of manifest pulmonary tuberculosis, a wholesale generalization that appears hardly justified by so limited a series of observations. The existing opportunity for infection is, in his opinion, the determining factor, and on it the development of the disease is dependent. (Why such respectable percentages of the non-exposed became tuberculous and of the exposed remained well is not explained.) A number of injurious influences, in women first and foremost parturition and sedentary occupation, in men especially, certain injurious influences relating to the occupation, are capable not alone of aggravating an existing tuberculosis, but also apparently of constituting a predisposing factor in the development of pulmonary tuberculosis.

Schwarzkopf's article is an interesting and valuable, but not a conclusive contribution to the literature of the still unsettled problems of the individual etiology of tuberculosis.

THE ETIOLOGY OF YELLOW FEVER.

Not long ago the Yellow Fever Institute of the U. S. Public Health and Marine-Hospital Service issued the Report of Working Party No 1, in which is described a protozoan parasite found regularly in certain mosquitoes that had bitten yellow-fever patients. This organism is described in detail and given the name of *Myxococcidium stegomyiæ*. On the face of it this report appeared to be one of the most important contributions yet made to the much-vexed question of the etiology of yellow fever. The question was, Would it stand the test of scientific criticism?

In this number of THE JOURNAL Dr. James Carroll of the U. S. Army brings forward certain facts that tend to weaken one's confidence in the soundness of the conclusions of Working Party No. 1. Dr. Carroll shows that the fusiform stage of the *Myxococcidium stegomyiæ*

can not be connected with the transmission of yellow fever, and that the organism is a yeast fungus found quite commonly in mosquitoes fed on overripe bananas purposely besmeared with yeast culture. Added to this we have the important fact that Dr. Carroll has not been able to find the organisms in mosquitoes known to have reproduced yellow fever in human beings after they had bitten yellow-fever patients early in the disease, the insects having been fed only on blood, dry sugar and water. Undoubtedly the members of Working Party No. 1 will not suffer Dr. Carroll's destructive criticisms to pass unchallenged, and their reply will be awaited with much interest.

There is another episode connected with the discovery of *Myxococcidium stegomyiæ* that adds further variety to the history of Working Party No. 1, and that is the assertion by J. C. Smith of New Orleans that he was "the first to have interpreted correctly and given value to the things found in the bodies of the mosquitoes infected from yellow-fever patients." Mr. Smith has submitted the assertion that in the Report of Working Party No. 1 he has not been given full recognition for his services in working out the history of the alleged parasite in the mosquito.[1] In order to vindicate fully his assertion, Mr. Smith, or some one else, must establish that the bodies seen in the infected mosquitoes are animal parasites. Mr. Smith and Working Party No. 1 should now join hands again, this time in the effort to meet Dr. Carroll's attack; then, in the event of successful defense of their assertions, they may turn to the less serious task of satisfactorily adjusting the dispute as to recognition. On the other hand, if the *Myxococcidium stegomyiæ* proves to be a harmless yeast, then this attempt to solve the etiologic problem of yellow fever, like so many others before it, will pass in silence into history.

A NEW DEPARTURE FOR CITY HEALTH BOARDS.

One of the most valuable contributions to the subject of municipal sanitation is the recent introduction by the Department of Health of New York City of trained nurses for public-school service and for visiting contagious disease cases. As is usual in public undertakings, the initiative and early experimenting were due to private individuals. The residents of the Henry Street Nurses' Settlement, situated in one of the most crowded quarters of New York City, became deeply impressed by the neglect of contagious cases, which naturally can not be treated in the ordinary course of district nursing.

In a report given in *Charities,* L. L. Dock, who is herself one of the nurses in this settlement, states that the supervision of the department of health is as complete and strict as is possible under the circumstances. Physicians are asked to immediately report contagious cases, and quarantine measures are adopted. Leaflets in several languages are distributed, giving explicit directions for domestic disinfection. In throat cases cultures are taken, and antitoxin is furnished free, and it is also administered by a physician from the department in response to calls from any part of the city. A medical inspector visits each contagious case regularly once a week to watch the progress and order disinfection. When the case terminates the rooms are disinfected, mattresses and bedding sterilized without cost to the patient's family, and the landlord is directed to clean and paint.

For three months last spring the nurses' settlement kept a nurse on contagious cases exclusively. Last June the department of health took over this service and organized municipal district nursing for contagious diseases throughout a definite area which could be managed by three nurses. A home was rented for them next the city diphtheria hospital, where they report daily. The department had six nurses at work among tuberculosis cases even earlier than this.

It is too soon to expect reports of large results; but no one familiar with tenement life in a great town can question the value of this service as an auxiliary to a general system of hospitals for contagious diseases. Such a system of hospitals is lacking in every American city so far as we are aware. It is still little more than planned in New York, and it will probably be long before the city possesses bed space for 75 per cent. of the cases, as we are told is the better fortune of London. The use of the visiting nurse is a unique and promising departure.

Even more unique and certainly more constructive is the use of the visiting nurse as an adjunct to the medical inspection of the public schools. Nurses are now attached to forty public schools in New York. Children who have trachoma, pediculosis, ringworm, eczema and other minor ailments which properly exclude them from school, are visited at home, mothers are instructed in caring for the diseases and the children are returned to school as promptly as possible. This service was begun when the alarming spread of trachoma among public-school children rendered necessary a school children's hospital for operative cases. Later the effort was directed to discovering the cases early enough to obviate the necessity for operation, and the system has gradually extended.

One of its best features is the early return of the children to school after absence for sickness and the consequent marked decrease in absenteeism and truancy. Under the usual system of medical inspection, the child is sent home with directions to have the scalp or eyes or ears treated. It is safe to say that in nine cases out of ten, the mother will not carry out the directions, and the case lapses into a sort of legalized truancy of indefinite duration justified by a more or less chronic ailment. Under the new system the nurse follows the child to its home, sees that the treatment is carried out

1. Science, 1903, xviii, 530-535.

and that the child duly returns to school. There is another large element of value in the hygienic instruction which the mother inevitably absorbs.

A RIGHTEOUS VERDICT AGAINST AN ANTIVIVISECTIONIST.

We have frequently called attention to the exaggerated statements and outrageous lies—no milder term will suffice—of the antivivisectionists, both in this country and in England, and to the uselessness, for this reason, of attempting to answer any of their so-called arguments. They make malicious and vindictive statements and these are reiterated in both countries, no matter who may be injured thereby, or whether or not they have been proved false. Without referring to more than one case, we cite that of Sir Frederick Treves, who has been, and still is, quoted as holding to views that he has repeatedly and publicly denied.

Last week in London, after a trial before Baron Alverstone, Lord Chief Justice of England, a verdict of $10,000 damages was rendered against one of the leading antivivisectionists of England—an event that, it is to be hoped, will have a tendency to check the zoöphiles in their "lust for slander." The defendant in the case was Stephen Coleridge, son of the late Lord Chief Justice Coleridge and a relative of the poet. He is the secretary of the London Antivivisection Society, and a leader in the perpetual antivivisection movement of Great Britain. At a public meeting held in London last May, he charged Dr. W. W. Baylis, a physiologist of London, with gross and deliberate cruelty while conducting experiments on dogs in his laboratory. It was alleged that no anesthetic had been administered, and that the struggles and sufferings of the animals were heartrending, etc. Dr. Baylis resented the imputations made against him, and did what it would be well for others in like circumstances to do, commenced proceedings for libel and slander. These have resulted in a verdict in his favor and the substantial damages of £2,000. In the trial it developed that Coleridge's only authority for his allegations were the statements of two young women who attended a lecture given by Professor Baylis at which demonstrations were made on a dog. The prosecution proved that the A. C. E. mixture was used through a laryngeal tube, and that the dog was thoroughly anesthetized.

According to cable reports, the verdict was a popular one, and was received with acclamation not only in the court room but throughout London. This is certainly gratifying, for experimental medicine in Great Britain has been practically throttled for years by absurd restrictive legislation. A man of Coleridge's social standing makes him more powerful for good or for harm than one of less prominence, but when he made public charges based on the statements of two women, without taking the trouble to verify the statements and without giving the one accused a chance to make an explanation, he was doing what the average antivivisectionist is in the habit of doing. Perhaps with prospective damages staring them in the face, Coleridge and his friends will be more chary in the future of making serious charges on evidence which will not stand legal scrutiny.

Professor Baylis is to be congratulated on having the courage to defend his good name, and should be thanked by all who have the interest of science at heart for the fight he made against these rabid and bigoted opponents of the splendid work that is being done in behalf of progressive medicine and for the relief of human suffering.

AN UNPROVED LIBEL ON THE PROFESSION.

During the first day's trouble with the Chicago striking street-car men, one of the Chicago papers printed a paragraph to the effect that when one of the non-union workers was injured and taken to a nearby drug store, the physician who was called to attend him refused to do so. The report stated that the physician asked the man for his union button and on being informed that he had none and did not belong to the union, the physician refused to do anything for him. We immediately made inquiry as to the truth of this and found that the information had been telephoned in by a reporter and that this reporter got his information from a druggist. The druggist on being questioned, acknowledged that he knew nothing about it. The probability is that the report was not true. We sincerely hope that no physician would so far forget himself and his duties to humanity as to refuse to render professional aid, no matter who the injured might be or what the circumstances. Some of the methods of the striking trades unionists are only worthy of the most sedulous avoidance—above all by honorable physicians.

A SUGGESTION REGARDING RECIPROCITY.

Elsewhere we print a communication from one of the members of the Board of Registration and Examination in Dentistry of New Jersey and also a resolution passed by the National Board of Dental Examiners, a voluntary body as we understand it, composed of members of the different state dental examining boards. The resolution contains a suggestion which we think might well be applied as one of the educational requirements for registration by those state licensing boards which are trying to arrange for reciprocity with others. The suggestion is that when an individual who is licensed in one state desires to move to another, he shall take with him a certificate from the registration board of his own state. If a man has a good standing among those with whom he has been living and can be vouched for by his state board as having conducted himself as he should and as being worthy to continue practice, a certificate of this ought to carry weight. We do not wish to suggest that this certificate alone should be all that is necessary, but it certainly would be a good thing to require on the part of the licensing boards. The proposition of having a sort of letter of dismissal from one state to another is a useful one in any case, but especially as a qualifying condition on which the applicant may be granted a license.

NEWSPAPER MEDICINE.

Newspaper medicine—of course we mean medical matters as described in newspapers—is sometimes correct, often startling and usually funny. Occasionally we find items that are both startling and funny, and last Sunday's Chicago *Tribune* contained one of these. It came in the form of a cable dispatch from the London correspondent. The item has several lines of display heads, the leader being: "Rivals Surgery Done by Lorenz." We are told that a Dr. Rabey of London contends that:

Numbers of hip disease cases are really nothing more than hip dislocations, which cause the leg to wither as the muscles become dry, and the natural oil which ought to feed the leg forms abscesses. When there are diseased bones, he admits he can do nothing. His method is to reset the dislocated bone after softening the tissues and ligaments around the affected part. Dr. Rabey, in contrast with Lorenz's half-hour performs the operation in from three to five seconds, and also instead of making his patients lie from six to twelve months in plaster paris Dr. Rabey promises to have them up walking about inside of forty-eight hours.

Further on we are told:

He operated yesterday on a youth of 18 who, when he was 11, was in the hospital for six months for hip disease, and since then he has walked on crutches. His left leg is four inches shorter than the right. Several weeks ago he commenced preparing for Dr. Rabey.

The preparation in this case consisted of the application of poultices of olive oil and mustard to the hip. With such preparations, of course the operation was greatly simplified, and so we need not be surprised when it is stated:

The operation yesterday lasted three and one-half seconds, immediately rendering the leg two and one-half inches longer. "He will be able to walk on Sunday" was Dr. Rabey's parting observation.

We are further told that Dr. Rabey "has dealt successfully with 154 similar cases and thrice failed, but in each instance the case proved to be genuine hip disease." Wonderful Rabey! poor Lorenz!!

Medical News.

ARKANSAS.

No Collusion Allowed.—The Government Medical Board at Hot Springs has authoritatively stated that any registered physician found to be assisting unregistered practitioners, by writing bathing directions or in any other way, will be rigidly dealt with.

Officers Elected.—At the annual meeting of the Pulaski County Medical Society, held at Little Rock, November 2, the following officers were elected: President, Dr. Strodder U. King; vice-president, Dr. John H. Kinsworth; secretary, Dr. Charles C. Stephenson, and treasurer and librarian, Dr. William C. Dunnaway, all of Little Rock.

Dr. Drennen Vindicated.—Immediately on the return of Dr. C. Travis Drennen from the East he demanded trial in the Circuit Court on the indictments recently returned against him by the grand jury, charging unprofessional conduct. The case was promptly dismissed by the court at the request of the prosecuting attorney on the ground that there was absolutely nothing in the testimony of the prosecuting witness which would warrant a conviction. The evidence was to be the same as that in the case of Dr. Thomas E. Holland, which was tried by jury a few days before, in which the judge instructed the jury to return a verdict of not guilty without leaving the jury box. These two gentlemen were indicted on the unsupported testimony of a man, confessedly in the nefarious business which they have been actively seeking to suppress. Hot Springs physicians are accordingly congratulating themselves on this signal victory over the "doctor-drummers," and on the complete exoneration of those who have been endeavoring to remove this reproach from the town.

CONNECTICUT.

Personal.—Dr. Charles S. Stern, Hartford, has sailed for Europe.——Dr. Charles W. Holbrook, health officer of East Haven, has resigned.——Dr. Henry Fleischner, attending physician at New Haven Dispensary for quarter of a century, has resigned.

Anti-Tuberculosis Lectures in Schools.—The members of the New Haven Medical Association and the superintendent of the public schools have arranged to give a series of lectures on tuberculosis, its cause and prevention. The first lecture will be given late in this month or early in December.

Eddyite Not Appointed Guardian.—Judge Cleveland of New Haven recently refused to appoint an Eddyite as guardian to the nine-year-old daughter of Isaac W. Stiles of New Haven. The judge made this decision after asking some questions as to prospective conduct in case of the serious sickness of the child.

October Mortality.—During October, 1,123 deaths occurred in the state, an annual death rate of 14.8 per 1,000. The deaths numbered 37 less than in September, and 10 less than in the same month of 1902, but 14 more than the average number of deaths in October for five preceding years. Infectious diseases, including diarrhea, caused 43.9 per cent. of the total mortality.

Infectious Diseases in October.—Smallpox—Putnam reports 8 cases; measles—255 cases are reported from 20 towns; scarlet fever—103 cases are reported from 32 towns; diphtheria—141 cases are reported from 36 towns; whooping cough—94 cases are reported from 13 towns; typhoid fever—168 cases are reported from 38 towns, and only 25 cases of consumption are reported during the month from 11 towns.

Dispensary Election.—At the annual meeting of the New Haven Dispensary, Dr. Charles A. Lindsley was elected president; Dr. John S. Ely, secretary; Drs. Francis Bacon, Charles A. Lindsley, Oliver T. Osborne, Louis S. De Forest, Charles J. Foote and Henry Fleischner, consulting physicians; Drs. William H. Carmalt, Henry L. Swain, Arthur L. Alling, John S. Ely, Robert E. Peck, Louis B. Bishop, Otto G. Ramsay, William Springer and Ralph A. McDonnell, attending physicians, and Dr. Thomas H. Young, apothecary.

ILLINOIS.

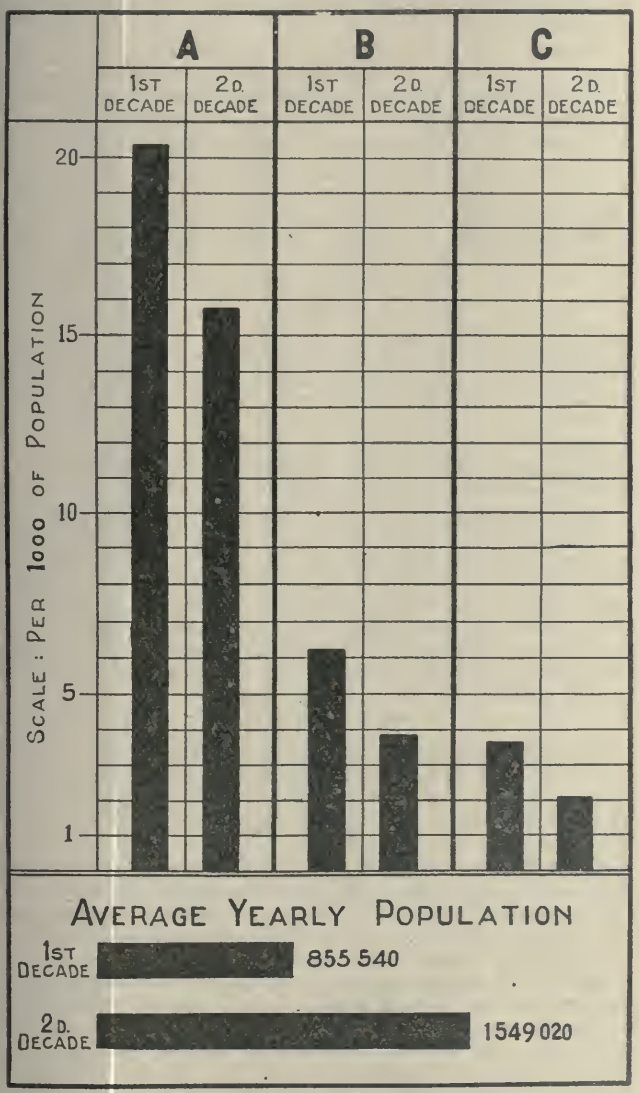
Infectious Diseases.—Diphtheria is said to be epidemic near Platteville, in Kendall County.——Typhoid is epidemic in Canton, where at least 60 cases exist.——In Streator there are said to be 6 or 8 cases of smallpox.——Dr. E. S. Baker of the State Board of Health has gone to Tuscola, Camargo, Pinkstaff and Mt. Carmel to inspect the sanitary arrangements with special reference to the reported cases of smallpox.——The smallpox situation in Belleville is encouraging. It is believed to be under control, and about 250 individuals are being vaccinated each day.

Chicago.

Fire in Dissecting Room.—A fire in the anatomic department of the building of the Northwestern University dental department, November 20, damaged the building to the extent of $35,000.

Dr. Musser at the Chicago Medical Society.—Dr. John H. Musser, President-elect of the American Medical Association, who was in Chicago at the conference of the officers of the sections of the American Medical Association, read a paper in the evening before the Chicago Medical Society, after which he was tendered a reception.

Personal.—Dr. E. H. Ruediger of the Memorial Institute for Infectious Diseases, Chicago, has been appointed assistant in the Serum Institute, Manila, P. I.——Dr. Albert C. Hemmett was thrown from his buggy and seriously injured in a collision with an electric car, November 8.——Dr. Chas. O. Young has severed his connection with Augustana Hospital.



Examination for Assistant Warden.—Fourteen applicants took the examination for assistant warden of Cook County Hospital, and of these four were successful. Dr. John B. Colwell obtained the highest mark and received the appointment. The other three on the eligible list in order of excellence are Drs. Arthur W. McClave, Victor Lespinasse, Chicago, and Joseph M. Kearney, Elgin.

Probert Fined.—The notorious Arthur C. Probert, vice-president of the "Christian Hospital," who was arrested on complaint of Dr. John B. Murphy and others on the ground that

their names were being used without authority on certificates of the hospital to induce other physicians to become members of the staff on payment of fees of varying amount, was fined $500 and costs, November 21, for fraudulent use of the mails.

Reduced Mortality.—Excepting pneumonia, all the acute infectious diseases show marked reductions in the mortality returns for the week ended November 21. Deaths from diphtheria are fewer than in any week since the schools opened. The number of cases reported is 30 per cent. less than in the previous week and the scarlet fever cases 26 per cent. less. No new cases of smallpox were discovered during the week. The total deaths for the week were 467, an annual death rate of 12.91 per 1,000. Pneumonia still heads the list, with 70 deaths, and then follow heart disease, with 63, and consumption, with 45.

Chicago Mortality for Twenty Years.—Dr. Arthur A. Reynolds, health commissioner, in a recent talk before the Sociology Club on "Sanitary Conditions in Chicago," briefly

rehearsed the sanitary, or rather unsanitary, conditions as they existed 65 years ago and compared them with the conditions of the present day. He presented a chart, which is herewith reproduced, which shows graphically the death rates during two decades—the first from 1883 to 1892, and the second from 1893 to 1902. The chart is explained as follows:

A—The death rate at all ages: In the first decade it was 20.35 per 1,000 of population. In the second decade it was 15.77—a decrease of 22.5 per cent. At the earlier rate—20.35 per 1,000 of population—there would have been 315,225 deaths during the last ten years, or 70,867 more than actually occurred.

B—The death rate of infants under 1 year of age: First decade this was 6.15 per 1,000 of total population; in the second decade it was 3.93—an increase of 36.1 per cent. or an equivalent of 34,270 fewer infant deaths in the last ten years.

C—The death rate of young children, between 1 and 5 years of age: It was 3.58 per 1,000 of total population in the first decade; it was 2.06 in the second—a decrease of 42.4 per cent., or 23,537 fewer children's deaths since 1892.

The "Average Yearly Population" of the last decade was 81 per cent. greater than that of the first—855,541 in the first; 1,549,019 in the last.

These figures are due in part to the bettered milk supply, antitoxin treatment of diphtheria, prophylaxis of tuberculosis and the educational propaganda of the Chicago Board of Health.

MARYLAND.

The Baltimore County Medical Association met November 19 at Halstead's, Park Avenue Heights. "State Organization of the Medical Profession" was discussed by Drs. S. T. Earle, J. M. B. Rowland, William J. Todd, G. Milton Linthicum and Joseph Gichner.

Baltimore Personals.—Dr. H. Barton Jacobs has returned from Newport.——Dr. William Osler has been elected president of the new Sydenham Society of London.——Drs. W. Ruice and B. W. Briscoe, resident physicians at Bayview Hospital, have accepted positions in West Virginia and western Maryland.——Dr. Howard A. Kelly will spend his holidays in Florida, as the guest of the chief of the Seminole Indians.

MASSACHUSETTS.

Bequest.—By the will of Elizabeth A. Whitney the New England Baptist Hospital benefits to the extent of $5,000.

Insane Hospital Regulations.—At a meeting of the Massachusetts State Board of Insanity, November 17, the matters of employing female nurses for insane men and of permitting families of married employes to live in the institutions were both favored, provided the expense did not prove too great.

Compulsory Vaccination Held Legal.—The Supreme Court of Massachusetts has declared that the law governing compulsory vaccination is constitutional and confirmed the sentence of the Municipal and Superior courts against a man named Mugford, who refused to be vaccinated or to allow his child to be vaccinated.

Hospital Dedicated.—Mt. Sinai Hospital, the new institution supported by Boston Jews, located at 17 Stamford Street, was dedicated November 22. It is a large four-story building, which has been remodeled to accommodate the out-patient department formerly located on Chambers Street. There are both medical and surgical wards with rooms for house physicians, matron and nurses.

Newburyport Hospital.—The new hospital at Newburyport, to be known as the Anna Jaques Hospital, is nearly completed. It comprises a group of buildings which include an administration building, two large wards, laundry and boiler house, all of which are practically finished. Plans are ready and contracts let for the operating building, which will be of concrete, two stories, and 40 by 75 feet.

Typhoid at Williams.—The eight or ten cases of typhoid fever occurring among Williams College students have led to a careful examination of the conditions by a board of experts called by President Hopkins. They report inability to find any evidence of any local source of infection and believe the cases are all imported. The prompt action of the college authorities meets the commendation of all.

MICHIGAN.

Swindle Milford Physicians.—The well-worn collection agency frauds are abroad in Michigan and have secured the usual number of victims, who have signed contracts without first examining them closely to see what they contained. These swindlers have recently victimized three or four physicians in Milford.

Consumption Sure-Cure Factories Shut Down.—Several patent medicine companies in Kalamazoo which have manufactured and exploited alleged cures for consumption have recently discontinued business, the reason given for the closure being pressure said to have been brought to bear by the United States government, for fraudulent use of the mails.

Medical College Under Ban.—At the October meeting of the State Board of Examiners in Medicine and Surgery, the Michigan College of Medicine and Surgery, Detroit, was taken from the list of accepted schools, the reason given by Dr. Oscar LeSeure, the local member of the board, being that it did not come up to the requirements demanded of such an institution, and was lacking in general equipment. The college authorities claim that this decision is due to a misunderstanding.

Comparative Morbidity.—For October, compared with the average for October in the last ten years, scarlet fever was

more than usually prevalent; and influenza, dysentery, intermittent fever, cholera infantum, remittent fever, erysipelas, whooping cough and measles were less than usually prevalent. For October, compared with the preceding month, neuralgia, influenza, scarlet fever, pneumonia, diphtheria and measles were more prevalent; and diarrhea, dysentery, cholera morbus, pleuritis, inflammation of bowels, cholera infantum, whooping cough and smallpox were less prevalent.

Communicable Diseases.—Meningitis was reported present in Michigan during the month of October, 1903, at 8 places; whooping cough at 19 places; measles at 21 places; smallpox at 42 places; diphtheria at 83 places; scarlet fever at 111 places; typhoid fever at 185 places and consumption at 242 places. Meningitis was reported at the same number of places; whooping cough at 13 places less; measles at 3 places less; smallpox at 15 places less; diphtheria at 10 places more; scarlet fever at 8 places more; typhoid fever at 3 places more, and consumption at 9 places more, when compared with the preceding month.

Lecture on Tropical Medicine.—Major Frank S. Bourns, M.D., formerly health officer of Manila, gave a lecture to the fourth-year medical students at the University of Michigan November 12. Dr. Bourns detailed the more important tropical diseases encountered in the Philippines, including dysentery, cholera, leprosy, plague, malaria and beri-beri; described the measures that have been carried out to check the various diseases, explained some of the unusual difficulties in preventive medicine among a partly civilized, superstitious and fatalistic population, and mentioned the lines along which further work in medicine would be likely to be carried out.

October Michigan Mortality.—There were 2,624 deaths reported to the Department of State for October, or 98 less than the number returned for the preceding month. The death rate was 12.5 per 1,000. There was a considerable decrease in deaths of infants and children, and a slight increase in deaths of elderly persons as compared with September. Important causes of death were as follows: Tuberculosis, 225; typhoid fever, 90; diphtheria, 78; scarlet fever, 7; measles, 3; whooping cough, 16; pneumonia, 143; diarrhea and enteritis, under 2 years, 173; cancer, 129; accidents and violence, 202. There was 1 death from smallpox. Somewhat increased mortality was shown from tuberculosis, diphtheria and croup and pneumonia. Typhoid fever caused 90 deaths as compared with 74 during the preceding month. There was a very large decrease in deaths reported from diarrheal diseases of children and also a considerable diminution in the number of deaths from cancer.

MISSOURI.

Smallpox.—Milan is reported to have a number of cases of smallpox and one death has occurred.

St. Louis College News.—Barnes Medical College has added a dental and a pharmaceutical department and is now on a university basis. It has opened with an increased number of students and has no university affiliation.

In Memory of Pollak.—The St. Louis Medical Society of Missouri, at its meeting, November 14, adopted memorial resolutions, setting forth the sense of the society's loss in the death of Dr. Simon Pollak, its "oldest and most illustrious member."

St. Joseph Personals.—Dr. J. J. Bentley has been re-elected superintendent of the Ensworth Hospital.——Dr. Frank O. Reynolds has been adjudged insane and has been taken to the State Hospital for the Insane, No. 2. His condition is said to be due to the use of cocain and morphin.

NEW YORK.

Smallpox Bills Audited.—The town board of Perry has audited bills aggregating nearly $3,000 as a direct result of the smallpox epidemic of last fall.

Consumptive Hospital Will Soon Open.—Advices from the state capitol indicate that the State Consumptive Hospital in the Adirondacks will be so far finished by the early spring as to accommodate fifty patients and by the summer the complete institution will be ready.

Personal.—Dr. Reed B. Bontecou, Troy, was tendered a reception on November 18 by the Rensselaer County Medical Association, of which he is one of the oldest members.——Dr. Chauncey P. Smith has been appointed medical officer of the Lackawanna Steel Company at West Seneca.——Dr. Thomas G. Nock has been elected mayor of Rome.

Smallpox in Medina.—There is an epidemic of smallpox in Medina. There have been 92 cases since October 1, and now 37 houses are quarantined in which are 47 persons stricken with the disease. All the cases thus far reported are of a mild form. A strong anti-vaccination sentiment exists in the town, which is responsible for the spread of the disease. The state health department has warned all the surrounding territory to quarantine against Medina.

Diphtheria.—The disease is epidemic in the village of Suffern, Rockland County, where 21 cases have already been reported. The board of education has ordered that the schools be closed. ——Two public schools in Auburn have been closed indefinitely on account of the prevalence of the disease in the northwestern part of that city, where 30 cases are said to exist.—— An epidemic of diphtheria exists at the Elmira Reformatory and a number of deaths are reported. The disease must have been brought there by some prisoner, as no cases have been discovered in the city outside of the prison.

Buffalo.

Midwives Fined.—Two Polish midwives were each recently fined $25 and costs in the Municipal Court for practicing without a license.

Personal.—Dr. and Mrs. John V. Woodruff are in the Bermudas.——Dr. Lawrence Hendee, a graduate of the University of Buffalo, and for several years past an instructor in anatomy at Cornell University, has been appointed volunteer assistant in surgery at the University of Königsberg, Germany.

Hospital Alumni Meet.—The annual meeting and banquet of the General Hospital Alumni Association was held November 7, when a committee was appointed to draw up resolutions on the death of Cornelius C. Wyckoff, and the following officers were elected: President, Dr. Peter F. Van Peyma; vice-president, Dr. Charles G. Stockton; and secretary and treasurer, Dr. William I. Thornton, all of Buffalo.

Dr. Marcy Wins Suit.—In the suit for alleged malpractice brought by Fred B. Lamphere against Dr. William H. Marcy, Buffalo, in which $10,000 was claimed on the ground that the defendant declared the child dead, although the child was alive and lived for several hours, the court decided that there was no cause for action because the possibilities of life in a prematurely born child of that age were so slight that it eliminated the question of damages from the case.

October Deaths.—The monthly report of the department of health for October shows a death rate of 13.16 per 1,000. The principal causes of death were as follows: Consumption, 28; cholera infantum, 4; diphtheria, 10; typhoid fever, 12; debility. 42; alcoholism, 2; cancer, 11; apoplexy, 23; valvular disease of the heart, 37; pneumonia, 16; appendicitis, 4; cirrhosis of the liver, 6; enteritis, 11; diabetes, 6; nephritis, 20; abortion and violence, 36. Total deaths, 442, as compared to 393 for October, 1902.

New York City.

New Dispensary and Dormitory for Bellevue.—The old building formerly used as the Bellevue Medical College was opened November 17 as a dispensary for out-patients. The building has been entirely renovated and made fireproof at a cost of $53,000.

Would Destroy "Lung Block."—A public hearing was held November 13, at which the destruction of what is known as the "lung block"—because of the prevalence of consumption—bounded by Houston, Catherine, Cherry and Market streets, was urged by the board of estimate.

Personal.—Dr. M. Allen Starr has been elected a corresponding member of the Neurological Society of the United Kingdom, London, in recognition of his contributions to the study of nervous diseases.——Dr. Frederick W. Chapin, who was recently removed to the Insane Pavilion of Bellevue Hospital, is reported as improving.

PENNSYLVANIA.

New Hospital for Pittsburg.—A contract for the Eye, Ear and Throat Hospital for Pittsburg has been awarded. The building will be three stories in height and will cost about $75,000.

Addition to State Hospital.—Directors of the Lackawanna State Hospital, Scranton, have decided to make a four-story addition to the hospital building, which will be of brick, and fireproof, and will cost about $100,000.

Contagious Diseases in Pittsburg.—Pittsburg is suffering from typhoid fever, scarlet fever, diphtheria and smallpox. During the week ended November 14, the physicians of the bureau of health vaccinated about 16,000 individuals.

Dr. Ridenour Acquitted.—Dr. Samuel H. Ridenour, Pittsburg, who was charged with selling cocain without a prescription, was found not guilty. The defendant admitted that he had sold the drug and pleaded ignorance of the law restricting its sale.

Smallpox.—Two new cases have developed at Jeannette.——In Pleasant Valley, 13 cases are said to exist, and one patient has died.——Alliance has an epidemic of the disease and the health boards of Allentown and Catasauqua have adopted a resolution requesting the electric and steam railways to discontinue selling tickets to Cementon, Sigfried and Northampton until all danger of infection is passed.

Advisory Medical Board for Penitentiary.—Drs. William D. Robinson and Charles D. Hart, inspectors of the Eastern State Penitentiary, who were appointed a special committee to obtain the voluntary services of an advisory board of physicians and surgeons, have been successful in their endeavors. The members of the advisory board are: Dr. Robert G. LeConte, surgery; Dr. Judson Daland, medicine; Dr. George E. de Schweinitz, ophthalmology; Dr. Francis A. Packard, laryngology, rhinology and otology, and Dr. Horace Philips, neurology, all of Philadelphia.

Philadelphia.

Personal.—Dr. Alfred Heineberg has been appointed assistant demonstrator of gynecology in Jefferson Medical College.——The University of Toronto has conferred on Dr. W. W. Keen the degree of LL.D.

Woman's College Hospital.—The Woman's Medical College contemplates building a hospital and has issued a circular asking the alumnæ to subscribe to the project. About $75,000 is needed for the building and $425,000 for endowment. Friends of the institution will also be asked for aid.

Hospital Site Purchased.—The Mount Sinai Hospital Association, which was organized three years ago, and which has since maintained a large dispensary in the slum district, has recently purchased at a cost of $35,000 a site for a hospital. The project is supported by several benevolent and wealthy Jews of the city.

Weir Mitchell Guest of Honor.—At the regular meeting of the Medical Club of Philadelphia, November 20, which was of the nature of a smoker held four times a year at the Hotel Bellevue, Dr. S. Weir Mitchell was the guest of honor. Preceding the meeting the president, Dr. Edward E. Montgomery, entertained Dr. Mitchell and a few professional friends at dinner.

The Smoke Nuisance.—A subcommittee of the city councils has approved an ordinance to abate the soft coal smoke nuisance. This also provides that no sulphurous fumes or noxious odors shall be permitted to escape from any chimney or smokestack within the city limits. A penalty of $50 is fixed for each violation. Locomotives and steamships are exempted. The question of legality is to be determined by smoked glass of such a degree of darkness that any smoke visible through the glass is of illegal darkness in color.

The Contagious Disease Situation.—Of the 373 new cases of contagious diseases reported for the week ended November 21 34 per cent. were from wards surrounding the Municipal Hospital. The latter condition is due, Director Martin thinks, to a "leak" in the Municipal Hospital. The new cases of smallpox numbered 68, double as many as for the week before. Dr. Martin has no reason to think, he says, that smallpox will become epidemic. The chief reason assigned for its continuance is the fact that victims ignorantly or intentionally fail to call in a physician and therefore keep the health authorities from learning of the cases. Many of the recent cases have occurred among a religious sect of negroes who depend on prayer and incantations and resist medical treatment. The founder and head of the church is said to have fled the city to escape arrest. Some of the leaders are in quarantine and will probably be tried for practicing medicine without license. The health authorities, with a detail of police, recently made a raid on some four hundred of the congregated sect and forcibly vaccinated all who were not properly protected by vaccination.

GENERAL.

Tuberculosis Sanitarium on Isle of Pines.—The climate of the Isle of Pines, West Indies, is said to be as well fitted for the residence of consumptives as is that of Colorado and a tuberculosis sanitarium is projected.

The Phipps Institute Lectures.—The next lecture in this course will be given in Philadelphia, Thursday, December 3, by Dr. William Osler, Baltimore, the subject being "The Home and Its Relation to the Tuberculosis Problem." These lectures are semi-popular in character and all are invited to attend them.

Manila Medical Society.—At a recent monthly meeting of this society, Major J. M. Banister of the First Reserve Hospital read a very interesting paper on "The Treatment of Strangulated Hernia." Dr. R. P. Strong exhibited a collection of intestinal parasites. Capt. Edward L. Munson, acting commissioner of public health, read a paper on "The Movement of the Bubonic Plague in the Philippines." There was a good attendance and discussion was lively. The society is reported to be growing.

Conference of Section Officers.—A conference of the officers of the sections of the American Medical Association was held at Chicago, November 18, in response to an invitation sent out by the President-elect, John H. Musser. The various sections were represented as follows: Practice of Medicine, Alexander Lambert, New York; J. L. Miller, Chicago, and George Dock, Ann Arbor, Mich. Obstetrics and Diseases of Women, L. H. Dunning, Indianapolis; C. L. Bonifield, Cincinnati, and Henry P. Newman, Chicago. Surgery and Anatomy, E. Wyllys Andrews, Chicago; A. J. Ochsner, Chicago, and W. J. Mayo, Rochester, Minn. Hygiene and Sanitary Science, Arthur R. Reynolds, Chicago, and H. M. Bracken, Minneapolis. Ophthalmology, Albert E. Bulson, Jr., Ft. Wayne, Ind., and Frank Allport, Chicago. Diseases of Children, Charles G. Kerley, New York; C. F. Wahrer, Ft. Madison, Iowa, and John C. Cook, Chicago. Stomatology, Eugene S. Talbot, Chicago. Nervous and Mental Diseases, F. Savary Pearce, Philadelphia; David I. Wolfstein, Cincinnati, and Hugh T. Patrick, Chicago. Cutaneous Medicine and Surgery, Henry G. Anthony, Chicago, and R. R. Campbell, Chicago. Laryngology and Otology, J. F. Barnhill, Indianapolis, and Otto T. Freer, Chicago. Materia Medica, Pharmacy and Therapeutics, C. S. N. Hallberg, Chicago, and N. S. Davis, Jr., Chicago. Pathology and Physiology, L. Hektoen, Chicago, and Frank B. Wynn, Indianapolis. There were present also: J. H. Musser, President-elect, Philadelphia; George F. Jenkins, Fourth Vice-President, Keokuk, Iowa; M. L. Harris, Resident Trustee, Chicago, and George H. Simmons, Secretary, Chicago. A continuous day's session was held, and in the evening a dinner was tendered by the resident section officers to the visitors. Matters of special importance to the sections were discussed, such as places of holding section meetings, modes of election of officers, need of more or less permanency in the office of section secretary, need of collaboration in section work to the end that any given subject may be discussed in one section only, the advisability of the smaller sections having a shorter program and hold only half-day sessions each day, giving their members a chance to attend other sections, etc. It is believed that the conference was of great value and will result in much good and will make the section sessions of more practical value to all than has been the case in the past.

CANADA.

The New Hospital Opened at Moncton, N. B.—Moncton's new hospital building was formally opened November 11. The building is a modern one, and cost $20,000.

Personal.—Dr. Herald has resigned as secretary-treasurer of the faculty of Queen's University, Kingston, and Dr. W. T. Connell has been appointed to the vacancy; Dr. A. R. B. Williamson has been appointed lecturer on medical jurisprudence and toxicology.——Dr. Von Eberts, registrar of the faculty of medicine of McGill University, has resigned and will resume private practice.——Dr. D. A. Shirres, Montreal, who has been studying in Europe, has been appointed neurologist to the Montreal General Hospital.

Smallpox and Diphtheria in Ontario.—Dr. Hodgetts, provincial medical health inspector for Ontario, has been examining into the smallpox outbreak in Tweed, Hastings County, Ont., and reports that there have been 29 cases in 8 houses.——Dr. Bryce, secretary of the Ontario Board of Health, has reported that in August last 27 municipalities reported 122 cases of diphtheria, with 24 deaths; in September 38 municipalities reported 240 cases, with 30 deaths; in October 52 municipalities reported 464 cases, with 54 deaths, and returns so far for the month of November indicate that the disease is still spreading. In the City of Toronto alone in August there were 51 cases reported; in October the number had grown to 118 with 14 deaths. Out of 770 cases 445 have been treated in isolation hospitals.

Toronto University Seeks Better Hospital Facilities.—The medical faculty of the University of Toronto and the board of

trustees of the principal hospitals are at present negotiating with a view to arranging for accommodation and regulations to secure better hospital facilities for medical education. The committee appointed for the purpose from the university requires that the house staff of these hospitals be large enough to efficiently carry on the work, that one member of each staff be detailed to do clinical laboratory work exclusively, that the staffs be divided into seniors and juniors, the seniors to retire every six months, that no fees be paid any members of the house staff by physicians or patients and that each hospital board appoint an official anesthetist. With a view to increasing the material for clinics the committee urges that all patients in public wards be placed in charge of the clinical staff. They also require better facilities for the conduct of out-patient departments. Better facilities for the study of pathology were asked by the committee, increasing the number of autopsies and the keeping of proper records. In the Children's Hospital at Toronto, all these regulations have been in force for considerable time.

FOREIGN.

The Austrian Trouble.—Our Vienna exchanges state that the recent discussions in the Landtag on the subject of vivisection, with the insults to the medical profession mentioned in this column last week, are to be published in a separate pamphlet for distribution among the public. The resolution to publish the pamphlet was passed by the majority of the house. Our exchanges refer to this proceeding as presenting only too true a picture of the condition of ignorance and hostility to science prevailing throughout the masses in Austria at the opening of the twentieth century. The resolution adopted by the Vienna Medical Chamber calling on the members of the national board of health to resign, has not been complied with by the latter.

Quincke's Silver Jubilee.—October 29 was the twenty-fifth anniversary of the day on which Prof. H. Quincke assumed charge of the medical clinic at Kiel. He was previously at Berne, and was summoned to Kiel as the successor of Professor Bartels. His former assistants gathered from far and near to do him homage on his jubilee, and the attendance at the banquet was limited to those who had served as his aids at any time. The next day he invited them all to lunch at his home, and the festivities closed with a torchlight procession in his honor arranged by the students. The list of his assistants includes such names as Bertheau, Kirchhoff, Brockendahl, Hoppe-Seyler, von Starck and Glaevecke. Quincke is now in his sixty-first year.

LONDON LETTER.

Malaria: The Anti-Mosquito Campaign.

Reports from all parts of the British Empire show that the anti-mosquito campaign is being carried on with the most gratifying success. At the opening meeting of the Royal Colonial Institute Major Ronald Ross pointed out that in the once deadly colony of Lagos, thanks to the zeal of Sir W. MacGregor, the governor who is a doctor, malaria has lost its terrors. The difficulties to be contended with were great, for Lagos itself is built on a low and swampy territory, and surrounded by dense forests. In the medical report of Hong Kong for 1902 the deaths of the Chinese from malarial fever are stated to have been 887 in 1900, 541 in 1901, and 303 in 1902. But perhaps the most striking and rapid results have been obtained at Ismailia on the Suez Canal. In a little over 6 months one class of mosquito was practically banished from the town and coincidently the amount of malarial fever diminished. In the first 6 months of the present year there were only 3 cases in hospital against 52 for the same period of last year.

The King's Sanatorium.

The king has laid the foundation stone of the sanatorium for the treatment of consumption which is being built in Surrey. The cost is defrayed by the munificence of a private donor [Sir Ernest Cassel, according to press dispatches.—ED.] who wished to remain anonymous, and placed a large sum at the disposal of the king for the purpose. Sir W. Broadbent, Sir F. Treves, Sir H. Weber, and other members of the committee were present at the ceremony. The sanatorium will be replete with every convenience and invention, and will be one of the most perfect ever erected. It will be a long two-story building overlooking the Valley of the Rother to the South Downs. There will be accommodation for 100 poor and 12 well-to-do patients. Each patient will have a separate room, and there will be a balcony on which the patients can sit out and on which the beds can be wheeled. The site is ideal; there are sandy soil, southern aspect and pine woods, which protect against north and northeast breezes. The ground slopes gently to the south and is well wooded, the western border consisting of open moorland ending in a ravine. The climate is rendered mild and equable by proximity to the sea and shelter from the hills. The primary object is to provide accommodation for a class above the very poor (who are already provided for) such as teachers, governesses, clerks, shop assistants, etc.

Typhoid Fever in Glasgow Due to Contaminated Shellfish.

An outbreak of typhoid fever in London due to shellfish contaminated with sewage was recently described in THE JOURNAL. A similar outbreak has just occurred in Glasgow. The health officer has reported 18 cases, all giving the same history. The patients had been on a holiday at the same coast town at the probable time of infection and consumed uncooked shellfish (cockles or mussels). In addition 8 cases occurred in one family who had not visited the town in question but had eaten shellfish brought from it. The dates of sickening seemed to show that the mother of the family had contracted the fever from the shellfish and that the other members were infected through her. The shellfish were gathered by the visitors from an area of foreshore polluted by the sewage of the town. Bacteriologic examination of the shellfish showed evidence of fecal pollution in almost every specimen—the presence of the *Bacillus coli*. On the other hand, shellfish obtained at a distance of 1½ to 2 miles from the sewer outfall were entirely free from the bacillus. Only in the third series of specimens examined was any trace of an organism resembling the typhoid bacillus found and there it was very abundant. This bacillus was obtained in great numbers and almost in pure culture in one plate. The shellfish which yielded this was a cockle found on the surface about 200 yards from the sewer outfall. Surface cockles are regarded by cockle gatherers as sick and are avoided, but it is just these the inexperienced would pick up. The bacillus had all the microscopic and cultural characters of the typhoid bacillus and it gave the Widal reaction.

Correspondence.

One of the Causes of the Chaos in Posology.

NEW YORK, Nov. 21, 1903.

To the Editor:—In my communication, "Dose of Carbolic Acid and Dosage in General," which appeared in THE JOURNAL, November 21, I said that our so-called science of posology is in an uncertain, chaotic condition. There are many intrinsic reasons for this chaos and uncertainty, but I wish to call attention to one cause, which contributes toward that chaos, sows confusion in the physician's mind and not infrequently throws him off the track. Two or three days ago the question of dosage came up. A medical friend, a recent graduate, said that the dose of belladonna as given in the books is entirely too small. He has a child under treatment suffering with pertussis; he has been trying to put it under the influence of belladonna. He started with one-drop doses of the fluid extract, but as they had no effect, he began gradually to increase the dose, until now he is giving 8 drops three or four times a day. "And even under these doses the physiologic effect is very slight. There is hardly any dilatation of the pupils, flushing of the face or dryness of the throat," etc. Though I am rather used to large doses, this statement surprised me. I am familiar enough with belladonna to know that 8 drops of the fluid extract is a heroic dose for a child 8 or 9 years old. I suggested that the fluid extract must have been old and ineffective, or otherwise the child must possess a peculiar immunity toward belladonna. An examination at the drug store of the bottle of the fl. ext. belladonna showed a sediment at the bottom, and the appearance of the bottle indicated that it must have been on the druggist's shelves for a long time. An original bottle of the fluid extract of belladonna was obtained from a prominent manufacturer, and one drop of that produced a decided and unmistakable physiologic belladonna effect. I shudder to think what the result might have been if this physician, misled by his experience, had ordered for a child 8 drops of an efficient fluid extract of belladonna several times a day. The above is, I am sure, not a solitary

case. We very frequently deal with different galenical preparations of the same drugs, one of which may be twenty times stronger than another.

The above incident teaches us two important lessons: 1. In prescribing galenicals we should make sure that they are comparatively fresh and come from high-class manufacturers. 2. In the cases of drugs which contain active principles fully representing the virtues of the drugs, those active principles are by far preferable to the crude drug or to its galenic preparations. Atropin is always atropin, but belladonna is not always belladonna, and the same may be said of dozens of other important drugs.

WILLIAM J. ROBINSON, M.D.
119 East 128th Street.

Interchange of Licenses.

NEWARK, N. J., Nov. 20, 1903.

To the Editor:—At the meeting of the National Board of Dental Examiners, held at Nashville, N. C., last August, the following resolution was unanimously adopted after full discussion:

Resolved, That an interchange of license to practice dentistry be, and is hereby recommended to be, granted by the various state boards, on the following specific conditions:

Any dentist who has been in legal practice for five years or more, and is a reputable dentist of good moral character, and who is desirous of making a change of residence into another state, may apply to the examining board of the state in which he resides, for a new certificate which shall attest to his moral character and professional attainments, and said certificate, if granted, shall be deposited with the examining board of the state in which he proposes to reside, and the said board, in exchange therefor, may grant him a license to practice dentistry.

The above resolution has already been adopted by New Jersey, Ohio and Indiana. Medical men and dentists have been looking for a way to reciprocate in licensing. I think the above resolution comes very near the mark. The party desiring to locate in another state must get a certificate from his own state board first. It is presumed that if he is not all right he will not get such a certificate. The certificate under these conditions is like a letter of introduction. If the applicant is unworthy, his own board will know it, and will not grant the certificate. Such a certificate will be looked on as a kind of "letter of credit," and will not be given unless there is behind it a deposit that can always be drawn on. I think every state board of dental and medical examiners should adopt the principle.

CHAS. S. STOCKTON.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

WINKLEMANN'S OPERATION FOR HYDROCELE.

WASHINGTON, D. C., November, 1903.

To the Editor:—Will you kindly inform me what is Winklemann's operation for hydrocele? G. H. H.

ANSWER.—Winklemann's operation for hydrocele, which was referred to on p. 471 of this volume of THE JOURNAL, was first described in the *Centralblatt für Chirurgie*, Nov. 5, 1898, from which a description was taken, appearing in THE JOURNAL, Jan. 7, 1899. It consists in releasing the fluid through an incision 3 to 4 c.c. in length near the upper pole; then drawing the testis out of the scrotum outward as far as possible until stripped of its serous tunica vaginalis covering which is thus drawn wrong side out. A stitch or two is taken to prevent the testis from slipping back into its sac and the testis and tunica are replaced and skin sutured. Adherences soon form and the operation is asserted to be as effective as the more radical ones. The testis is left a trifle higher than normal and a slight edematous swelling may form for some time, but it is claimed there are no other inconveniences and the patient can be dismissed at once, as there is no danger of hemorrhage. The operation was performed by Winklemann under Schleich anesthesia.

Marriages.

WILDER TILESTON, M.D., Boston, to Miss Clare Williams of Chicago, November 18

GEORGE KRAMER HERZOG, M.D., to Miss Rae Cohn, both of San Francisco, October 7.

JOHN H. OLIVER, M.D., to Miss Nellie Northrop, both of Kewanee, Ill., November 11.

JULIUS ULLMAN, M.D., Buffalo, N. Y., to Miss Eugenia Platky of New York City, October 26.

WILLIAM T. MOFFETT, M.D., to Miss Myrtle M. Crow, both of Blue Mound, Ill., November 17.

CHARLES F. BLAKE, M.D., Baltimore, to Miss Adeline O'Bryon of Washington, D. C., November 10.

WILLIAM D. FERGUSON, M.D., to Miss Claudia Tallulah Irby, both of Laurens, S. C., November 18.

ROBERT E. MASON, M.D., Charlotte, N. C., to Miss Lucile McKie of Woodlawn, S. C., October 27.

JAMES WILLIAM LEWIS, M.D., Bowling Green, Ky., to Miss Susie Talbot of Valdosta, Ga., November 13.

SKOTTOWE BELLINGER FISHBURNE, M.D., to Miss Marion Lee Green, both of Columbia, S. C., November 11.

FRANK CLARENDON COOK, M.D., U. S. Navy, to Miss Eugenia Murdaugh Bain, at Norfolk, Va., November 11.

JOHN FRANCIS CORBIN, M.D., Knoxville, Ill., to Miss Marion Saybrook of Canada, at Knoxville, November 11.

JAMES H. HARGRAVE, M.D., Garysville, Va., to Miss Mary Elizabeth Peters, at Waverly, Va., November 11.

JOSEPH ALBERT CATLIN, M.D., of Church Hill, Md., to Miss M. Claiborne Grasty, at Baltimore, November 10.

WILLIAM M. COPENHAVER, M.D., Bristol, Va., to Miss Emma Charlsie Turner of Chattanooga, Tenn., November 25.

OLIVER WARDLAW LEONARD, M.D. Spartanburg, S. C., to Miss Corinne Louise Jones of Laurens, S. C., November 25.

JESSE HUGHES MABRY, M.D., Newport News, Va., to Miss Elizabeth Boatwright, at Mount Zion Church, Rockingham County, Va., November 10.

Deaths.

Joseph McFadden Gaston, M.D., was born Dec. 27, 1824, in Chester, S. C., the son of Dr. John Brown Gaston. He obtained his earlier education at South Carolina College, Columbia, where he received his A. B. degree in 1843. Immediately after receiving this degree he began reading medicine with his father, attended one course of lectures at the University of Pennsylvania and a second course at the Medical College of the State of South Carolina, Charleston, and received his medical degree from this institution, March 6, 1846. He practiced medicine with his father in the Charlestown District for six years, when he removed to Columbia. At the outbreak of the Civil War Dr. Gaston enlisted in the Columbia Grays and was soon appointed chief surgeon of the South Carolina forces. He was soon promoted to medical director under General Beauregard. He was then made chief surgeon of the third brigade of South Carolina Volunteers, and later participated in the Virginia and Pennsylvania campaigns as chief surgeon of division. Later he was ordered to report to the medical director of hospitals, and was sent to establish a general hospital at Fort Gaines, Ga., then at Fort Valley, where he remained on duty until the close of the war. At the cessation of hostilities Dr. Gaston went to Brazil, where he attended the lecture of the Imperial Academy of Medicine, and he was given the ad eundem degree in 1873. He practiced in Brazil for ten years, and then returned to America, locating in Atlanta. In 1884 he was elected professor of principles and practice of surgery in the Southern Medical College of Atlanta. He was a member of the American Medical Association and chairman of its surgical section in 1891 and 1892; president of the Southern Surgical and Gynecological Association in 1891; president of the American Academy of Medicine in 1895, and vice-president of the American Surgical Association in 1887. During his late years he was made honorary member of the Medical Society of Virginia; of the American Association of Obstetricians and Gynecologists of the Medical Association of Georgia; the Atlanta Society of Medicine and the Southern Surgical and Gynecological Association. Dr. Gaston had been in feeble health for a considerable time, and died at his home in Atlanta, November 15, from acute indigestion, aged 79. He was an authority widely known in this country and Europe in intestinal surgery and a pioneer in the surgical treatment of intestinal diseases. His contributions to literature were chiefly in the line of his specialty; those on yellow fever inoculation and surgery of the gall bladder and ducts are specially notable.

Cornelius C. Wyckoff, M.D. University of Buffalo, 1848, one of the most prominent medical men of western New York; the

only survivor of the original staff of the Buffalo General Hospital; president of the Board of Trustees of the Buffalo Eye and Ear Infirmary; a member of the American Medical Association; a charter member of the New York State Medical Association and sometime president of the Erie County Medical Society and the Buffalo Medical Society; at one time health officer of Buffalo and for many years a member of the board of censors of the New York State Medical Society, died at his home in Buffalo, November 7, from uremia due to kidney disease of long standing, aged 80. A special meeting of the Erie County Medical Society was held November 10, at which action was taken regarding the death of Dr. Wyckoff. The next regular meeting of the Buffalo Academy of Medicine, of which Dr. Wyckoff was a member, will be held in memory of him.

John K. Rainey, M.D. St. Louis Medical College, 1859, surgeon of the 111th Illinois Volunteer Infantry in the Civil War; chief surgeon of the first division, Seventh Army Corps in the Spanish-American War; department commander of the Grand Army of the Republic; surgeon of the Florida East Coast Railway; member of the St. John County Medical Society, and of the Florida Medical Association, died at his home in St. Augustine, November 9.

Robert D. Murray, M.D., surgeon, U. S. P. H. and M.-H. Service, stationed at Key West, Fla., who sustained severe injuries in a runaway accident at Laredo, Texas, November 15, died at that place, November 22. Dr. Murray was an old officer in the service, had been in charge of many stations in the department and, at the time his injuries were received, was engaged in the investigation of the yellow fever epidemic in Laredo.

James A. E. Steeves, M.D. University of Vermont, Burlington, 1884, of St. Johns, N. B., died at Phoenix, Ariz., November 14, from heart disease, aged 42. He was considered a leading authority on nervous diseases in the Province of New Brunswick, and for a number of years was assistant to his father, the late Dr. J. T. Steeves, who was superintendent of the New Brunswick Lunatic Asylum.

J. Frank Moore, M.D. University of New Orleans, 1858, member of the state medical societies of Mississippi and Texas, member of the Smith County (Texas) Medical Society, and of the Board of Medical Examiners for the Seventh District, a surgeon in the Confederate service during the Civil War, died at his home in Tyler, Texas, November 18, from bronchopneumonia.

Samuel S. Lathrop, M.D. College of Physicians and Surgeons, New York, 1900, pathologist to the William Backus Hospital, secretary of the Norwich (Conn.) City Medical Association, member of the New London County Medical Society and the Connecticut Medical Society, was killed by an automobile in Norwich, November 8, aged 39.

Archabale B. Temple, M.D. Western Reserve University, Cleveland, Ohio, 1883, a member of the Kansas State Medical Society, the International Association of Railway Surgeons, and first vice-president of the Southeast Kansas Medical Society, died suddenly in his office in Tulsa, I. T., November 11.

Sylvester J. Finley, M.D. Washington University School of Medicine, Baltimore, 1853, was overcome by paralysis while making a professional call in Lower Chanesford Township, York County, Pa., a few days before, died at his home in Castle Finn, November 12, aged 73.

James M. Mosgrove, M.D. Medical College of Ohio, Cincinnati, 1846, a member of the American Medical Association, a pioneer practitioner, and of late years a banker of Urbana, Ohio, died at his home in that city, from pneumonia, November 9, aged 78.

James Bond Read, M.D. University of Maryland School of Medicine, Baltimore, 1849, formerly of Savannah, Ga., died at his home in Greencove Springs, Fla., from pneumonia, November 10, after an illness of one week, aged 76.

William Ellery Channing Swan, M.D. Harvard University Medical School, Boston, 1865, for forty years a practitioner of Stoughton, Mass., died suddenly at his home in that city, November 10, from heart disease, aged 61.

Arthur E. Chatfield, M.D. Cleveland College of Physicians and Surgeons, Cleveland, 1896, of Cleveland, died at the City Hospital, Cleveland, November 10, from diphtheria, after an illness of three days, aged 43.

William Walker Duffer, M.D. Kentucky School of Medicine, Louisville, 1897, who practiced for some time in Knobel, Ark., died at his home in Louisville, November 10, after a long illness from tuberculosis, aged 40.

Edgar B. Lake, M.D. New York University, 1888, one of the city physicians of Amsterdam, N. Y., died at the Amsterdam Hospital, November 10, from burns received in some unexplained way.

Robert H. Peel, M.D. New Orleans School of Medicine, 1860, of Holly Springs, Miss., died suddenly from heart disease, November 6, while hunting in the Tallahatchie bottom, near Abbeville.

Thomas S. Cook, M.D. Howard University, Washington, D. C., 1894, died at his home in St. Paul, Minn., November 15, from acute gastritis, after an illness of only a few hours, aged 42.

James Zaimon Hunt, M.D. Long Island College Hospital, Brooklyn, N. Y., 1887, died at his home in Lowville, N. Y., November 13, from typhoid fever, after an illness of ten days, aged 42.

Samuel H. Headlee, M.D. Missouri Medical College, St. Louis, 1858, the oldest physician in Phelps County, Mo., died at his home in St. James, November 11, from paralysis, aged 80.

Richard E. Moody, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1872, mayor of Sweetwater, Texas, died at his home in that city, November 11, from heart disease.

Stephen Bennett, M.D. Dartmouth Medical College, Hanover, N. H., 1851, for 47 years a practitioner of Lithopolis, Ohio, died at his home in that place, November 15, aged 81.

Lucius B. Baker, M.D. University of Vermont, Burlington, 1872, died at his home in Russell, N. Y., November 2, aged 57.

James Cleveland Bivings, M.D. Medical College of Georgia, Augusta, 1868, died at his home in Dalton, Ga., November 12.

Deaths Abroad.

H. H. Hurdman, M.D., formerly in charge of the mounted police hospital at Dawson, N. W. T., died at his home in Johannesburg, South Africa, August 28, from pneumonia, aged 33.

Charles Marshall, M.D. University of Bishop's College, Montreal, 1879, of Huntingdon, P. Q., a member of the Medical Board of Governors of the Province of Quebec, died suddenly from apoplexy while visiting in New York City, November 13, aged 54.

State Boards of Registration.

COMING EXAMINATIONS.

Board of Medical Examiners of the State of California, City Hall, San Francisco, Dec. 1. Secretary, Geo. G. Gere, M.D., 825 Market St., San Francisco.

State Board of Examiners of Alabama, Montgomery, Dec. 1 to 10. Chairman, W. H. Sanders, M.D., Montgomery.

New Mexico Board of Health, Santa Fe, Dec. 7. Secretary, Dr. D. B. Black, Las Vegas.

Examining Board of Medical Society of Delaware, Dover, Dec. 8. Secretary, Dr. P. W. Tomlinson, Wilmington.

Board of the Homeopathic Medical Society of Delaware State and Peninsula, Wilmington, Dec. 8.

Ohio State Board of Medical Registration and Examination, Columbus, Dec. 8, 9 and 10. Secretary, Dr. Frank Winders, Columbus.

Missouri State Board of Health, Southern Hotel, St. Louis, Dec. 14, 15 and 16. Secretary, Dr. W. F. Morrow, Kansas City.

Medical Council, Philadelphia, Dec. 15. Secretary, Dr. Isaac B. Brown, Harrisburg.

Medical Examining Board of Virginia, Lynchburg, Dec. 15-18. Secretary, Dr. R. S. Martin, Stuart.

Colorado State Board of Medical Examiners, 1723 Tremont St., Denver, Dec. 22, 23 and 24. Secretary, Dr. S. D. Van Meter, Denver.

Arkansas Report.—Dr. J. P. Runyan, secretary of the State Medical Board of the Arkansas Medical Society, sends a report of a recent written examination held at Little Rock. Ten applicants were examined, of whom 8 passed and 2 failed. Two of those who passed and the two who failed were undergraduates. The examination covered seven subjects, 70 questions were asked and a percentage of 60 was required for passing. The colleges of the graduates are given below:

Colleges.	Year Grad.	Per Cent.
Jefferson Medical College	1903	87
Rush Medical College	1877	73
College of Physicians and Surgeons, Chicago	1903	89
Chattanooga Medical College (Tenn.)	1903	80
Harvey Medical College, Chicago	1897	74
University of the South, Sewanee, Tenn	1903	68

Association News.

Place of Session of the American Medical Association for 1905.—Attention is called to the action taken at the last session of the American Medical Association to the effect that any city wishing to invite the Association to meet at that place should present the invitation, together with all available facts concerning hotel accommodations, number and seating capacity of halls available for section meetings, intramural means of transportation, railroad facilities, etc., at least three months before the annual session of the preceding year. In accordance with the above, it is hoped that those cities which desire the Association in 1905 will send their invitations, with all information possible, on or before March 1, 1904.

[Signed] M. L. HARRIS, M.D.,
Chairman Committee on Place of Session and Transportation,
100 State Street, Chicago.

The Senn Prize Essay for 1904.

The Committee on the Senn Medal begs leave to call attention to the following conditions governing the competition for this medal for 1904: A gold medal of suitable design is to be conferred on the member of the American Medical Association who shall present the best essay on some surgical subject. The award will be made under the following conditions: (*a*) The name of the author of each competing essay must be enclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device. The title of the successful essay and the motto or device is to be read at the session at which the award is made, and the corresponding envelope is to be then and there opened and the name of the successful author announced. (*b*) All successful essays become the property of the Association. (*c*) The medal shall be conferred and honorable mention made of the two other essays considered worthy of this distinction, at a general meeting of the Association. (*d*) The competition is to be confined to those who, at the time of entering the competition, as well as at the time of conferring the medal, shall be members of the American Medical Association. (*e*) The competition for the medal will be closed on, and no essays received after, March 1, 1904. Communications may be addressed to any member of the committee, which consists of the following: Dr. James H. Dunn, Chairman, Minneapolis; Dr. M. L. Harris, 100 State Street, Chicago.; Dr. Floyd McRae, Atlanta, Ga.

The Public Service.

Army Changes.

Changes of station and duties of medical officers of the U. S. Army for the week ending Nov. 21, 1903:

Church, Jas. R., asst.-surgeon, granted fourteen days' leave of absence.

Appel, Aaron H., surgeon, granted thirty days' sick leave of absence.

Shockley, M. A. W., asst.-surgeon, granted thirty days' leave with permission to apply for ten days' extension.

Rand, I. W., asst.-surgeon, left Fort Wright, Wash., on thirty days' leave.

Wilson, Compton, asst.-surgeon, now at San Francisco, is relieved from duty in the Division of the Philippines and will proceed to Fort Howard, Md., for duty.

Schreiner, E. R., asst.-surgeon, relieved from duty at Fort Howard, Md., and will proceed to Fort McHenry, Md., for duty.

Bispham, W. N., asst.-surgeon, relieved at Fort McHenry, Md., to proceed to Fort Logan, Col., for duty.

Ashburn, Percy M., Usher, F. M. C., Russell, Fredk. F., Wolfe, Edwin P., first lieutenants, ordered to Presidio of San Francisco, Cal., for examination for promotion.

De Shon, Geo. D., Ford, Joseph H., Dean, Elmer A., and Cox, Walter, captains, Steer, Saml. L., Truby, Willard F., Williamson, L. P., Marrow, Chas. E., and Greenleaf, Henry S., first lieutenants, ordered to Army Medical Museum Building, Washington, D. C., for examination for promotion.

Little, Wm. L., asst. surgeon, relieved from further duty in Division of the Philippines, and ordered to Camp George H. Thomas, Ga., for duty.

Halsell, John T., contract surgeon, relieved at Fort McIntosh, Texas and ordered to Eagle Pass, Texas, to relieve contract surgeon Victor E. Watkins, U. S. Army, who is ordered to San Francisco, Cal., to sail December 1 for Philippine service.

Treuholtz, Clarence A., contract surgeon, relieved at Fort Apache, Ariz., and ordered to duty at the General Hospital, Fort Bayard, New Mexico.

Hepburn, James H., contract surgeon, granted twenty days' leave of absence from Fort Douglas, Utah.

Newlove, George, contract surgeon, relieved from duty at Fort Wood, New York, and ordered to Fort Ethan Allen, Vt., to accompany troops of the 2d Cavalry to Philippine service on the *Kilpatrick*, sailing from New York about December 15.

Cooke, Robert P., contract surgeon, returned from temporary duty at Fort Screven, Ga., to his proper station, Camp George H. Thomas, Ga., and is now under orders for change of station to Fort Wood, New York.

Arwine, James T., contract surgeon, granted a month's leave of absence about November 20 from the Presidio of San Francisco.

Unger, Isedor M., contract surgeon, granted three months' leave of absence from the Division of the Philippines, with permission to visit the United States.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending November 21:

Freeman, G. F., P. A. surgeon, detached from the Naval Hospital, Chelsea, Mass., and ordered to the Naval Station, Guam.

Brownell, C. D., surgeon, detached from the *Alliance* and ordered home to await orders.

Fiske, C. N., P. A. surgeon, ordered to the Naval Hospital, Boston, Mass.

Angeny, G. L., P. A. surgeon, detached from the *Essex* and ordered to the Naval Home.

Dickson, S. H., medical inspector, ordered to the *Kearsarge* as fleet surgeon of the North Atlantic Station.

McClurg, W. A., medical inspector, detached from the *Kearsarge*, and ordered home to wait orders.

Gill, J. E., asst.-surgeon, ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Nov. 19, 1903:

Williams, L. L., asst.-surgeon-general, to proceed to New York, N. Y., for special temporary duty and as inspector of the Purveying Depot.

Carmichael, D. A., surgeon, bureau letter of October 5 granting Surgeon Carmichael leave of absence for thirty days from October 16, amended so as to read twenty-four days from October 16.

Wasdin, Eugene, surgeon, granted leave of absence for one month from December 7.

Magruder, G. M., surgeon, granted leave of absence for two days from November 17.

Rosenau, M. J., P. A. surgeon, relieved from duty at Vera Cruz, Mexico, and directed to rejoin his station in Washington, D. C.

Parker, H. B., P. A. surgeon, relieved from duty at Vera Cruz, Mexico, and directed to return to the Bureau at Washington, D. C.

Lumsden, L. L., P. A. surgeon, granted leave of absence for ten days from November 15.

Ramus, Carl, asst.-surgeon, granted leave of absence on account of sickness for nine days from October 28.

Stansfield, H. A., asst.-surgeon, to report to the director of the Hygienic Laboratory for duty.

Goldberger, Joseph, asst.-surgeon, to proceed to Laredo, Texas, for special temporary duty.

Berry, T. D., asst.-surgeon, to proceed to Cleveland, Ohio, and assume temporary command of the service at that port during absence of medical officer in command; on completion of which to rejoin his station.

Francis, Edward, asst.-surgeon, granted leave of absence for fourteen days. Relieved from duty at Vera Cruz, Mexico, and directed to return to the Bureau at Washington, D. C.

Boggess, J. S., asst.-surgeon, granted leave of absence for one month from December 15.

Pierce, C. C., asst.-surgeon, detailed as inspector of unserviceable property on the steamer *Bratton*.

Ebersole, R. E., asst.-surgeon, to proceed to San Antonio, Texas, for special temporary duty.

Ashford, F. A., asst.-surgeon, to proceed to Chicago, Ill., and report to medical officer in command for duty and assignment to quarters.

Roberts, Norman, asst.-surgeon, on being relieved from duty at Chicago, Ill., to proceed to San Diego, Cal., and assume command of the service at that port.

Frick, John, A. A. surgeon, granted leave of absence, on account of sickness, for thirty days from July 31.

Hallett, E. B., A. A. surgeon, granted leave of absence for four days from November 25.

Maguire, E. S., pharmacist, granted leave of absence for thirty days from December 5.

Southard, F. A., pharmacist, granted leave of absence for seven days from November 14, 1903, under paragraph 210 of the Regulations.

Neves, George, pharmacist, directed to proceed to Chicago, Ill., and report to the medical officer in command for duty and assignment to quarters.

APPOINTMENT.

Ashford, Francis Asbury, of the District of Columbia, commissioned (recess) as asst.-surgeon in the Public Health and Marine-Hospital Service.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Nov. 20, 1903:

SMALLPOX—UNITED STATES.

California: Los Angeles, Nov. 1-7, 1 case.
Louisiana: Baton Rouge, Oct. 24-Nov. 7, 2 cases.

Massachusetts: Lawrence, Nov. 8-14, 1 case.
Mississippi: Natchez, Oct. 25-Nov. 7, 3 cases.
Nebraska: Omaha, Aug. 1-31, 3 cases.
New Hampshire: Manchester, Nov. 8-14, 2 cases.
New Jersey: Camden, Nov. 8-14, 1 case.
New York: Buffalo, Nov. 2-9, 1 case.
Ohio: Cincinnati, Nov. 6-13, 9 cases; Youngstown, Nov. 8-14, 12 cases.
Pennsylvania: Nov. 8-14, Philadelphia, 34 cases, 1 death; Pittsburg, 49 cases, 5 deaths.
South Carolina: Charleston, Nov. 8-14, 1 case.
Texas: San Antonio, Oct. 1-31, 20 cases.
Utah: Salt Lake City, Nov. 1-7, 1 case.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Oct. 25-31, 11 cases.
Brazil, Pernambuco, Sept. 17-30, 15 deaths; Rio de Janeiro, Oct. 11-18, 40 cases, 38 deaths.
Chile: Antofogasta, Sept. 1-30, 23 deaths.
China: Hongkong, Sept. 27-Oct. 3, 1 case, 1 death.
Ecuador: Guayaquil, Oct. 11-31, 2 deaths.
France: Marseilles, Oct. 1-31, 21 deaths; Paris, Oct. 25-31, 4 cases.
Great Britain: Glasgow, Oct. 30-Nov. 7, 17 cases; London, Oct. 25-Nov. 7, 17 cases; Manchester, Oct. 18-24, 5 cases; Newcastle-on-Tyne, Oct. 25-31, 6 cases.
Italy: Catania, Oct. 29-Nov. 5, 1 death.
Malta: Oct. 18-31, 3 cases, 2 deaths.
Mexico: City of Mexico, Oct. 26-Nov. 1, 3 cases, 1 death.
Netherlands: Amsterdam, Nov. 1-7, 2 cases.
Porto Rico: San Juan, Oct. 31, 2 cases.
Russia: Moscow, Oct. 18-24, 2 deaths; Odessa, Oct. 11-18, 6 cases; St. Petersburg, Oct. 18-24, 27 cases, 1 death.
Spain: Barcelona, Oct. 18-31, 2 deaths.
Turkey: Constantinople, Oct. 26-Nov. 1, 2 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Oct. 11-17, 3 deaths; Madras, Oct. 3-9, 1 death.
Turkey: Siarbikir, Oct. 8-15, 5 deaths daily; Severek, Oct. 8, present.

YELLOW FEVER—UNITED STATES.

Texas: Cannel, to Nov. 18, 19 cases; Laredo, Nov. 11-19, 195 cases, 17 deaths; Minera, Nov. 11-13, 9 cases; San Antonio, Nov. 12-14, 3 cases, 3 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Oct. 11-18, 2 cases.
Mexico: Oct. 11-24, Citas, 2 deaths; Cuidad Victoria, 23 cases, 18 deaths; Linares, 412 cases, 36 deaths; Merida, 20 cases, 7 deaths; Nuevo Laredo, Oct. 11-Nov. 14, 52 cases, 21 deaths; Oct. 11-24, Progreso, 1 case, 1 death; Salina Cruz, 8 cases, 2 deaths; Tehuantepec, 4 deaths; Vera Cruz, 66 cases, 32 deaths.
Venezuela: Barquisimeto, Oct. 12-13, 2 deaths; Cagua, Oct. 13, present; Maracaibo, Oct. 18-24, 1 case, 1 death.

PLAGUE—UNITED STATES.

California: San Francisco, Nov. 4-7, 2 cases, 2 deaths.

PLAGUE—INSULAR.

Brazil: Rio de Janeiro, Oct. 11-18, 44 cases, 22 deaths.
British East Africa: Port Elizabeth, Sept. 20-Oct. 3, 3 cases, 2 deaths.
China: Hongkong, Sept. 27-Oct. 3, 2 cases, 2 deaths.
Egypt: Alexandria, Oct. 11-23, 16 cases, 11 deaths.
India: Bombay, Oct. 14-20, 60 deaths; Calcutta, Oct. 11-17, 17 cases, 17 deaths; Karachi, Oct. 4-18, 12 cases, 10 deaths; Madras, Oct. 10-16, 1 death.
Mauritius: Oct. 16-22, 100 cases, 66 deaths.

Medical Organization.

Florida.

SUWANEE COUNTY MEDICAL ASSOCIATION.—A number of physicians of the county met in Live Oak, November 2, and organized a county society with the following officers: Dr. Henry F. Airth, Live Oak, president; Dr. Gelon B. Smithson, Wellborn, vice-president; Dr. W. C. White, Live Oak, secretary; Dr. C. S. Brown, Live Oak, treasurer, and Drs. Silas T. Overstreet, Live Oak; F. E. Thomasson, Live Oak, and Adelbert D. Puterbaugh, Branford, censors.

Illinois.

LIVINGSTON COUNTY MEDICAL SOCIETY.—At the sixth semi-annual meeting of the society, held in Pontiac, November 12, the committee on affiliation with the Illinois State Medical Society reported favorably, and the changes in the constitution necessary to make it conform to that of the state society were adopted.

KANE AND MCHENRY COUNTIES MEDICAL SOCIETY.—At the seventy-seventh semi-annual meeting of the Fox River Valley Medical Association, in Aurora, November 10, after an exposition of the standard plan of organization by Dr. Malcolm L. Harris, Chicago, representing the state society, it was agreed that the society should ask for recognition from the Illinois State Medical Society as the official society of Kane and McHenry counties. The following officers were then elected: President, Dr. Henry J. Gahagan, Elgin; vice-president, Dr. Frank H. Jenks, Aurora, and secretary and treasurer, Dr. J. Forrest Bell, Elgin.

Indiana.

PORTER COUNTY MEDICAL SOCIETY.—Dr. George F. Keiper, Lafayette, councilor for the Tenth District, announces the reorganization of the Porter County Medical Society.

Iowa.

OSCEOLA COUNTY MEDICAL SOCIETY.—The physicians of Osceola County met at Sibley, November 10, and organized a county society with the following officers: Dr. William E. Ely, Ocheyedan, president; Dr. Clinton C. Cady, Harris, vice-president; Dr. Felix J. Langenhorst, Ashton, secretary, and Dr. Louis H. Heetland, Sibley, treasurer.

GREENE COUNTY MEDICAL SOCIETY.—A number of the medical fraternity of Greene County met at Jefferson, November 9, and organized a society with the following officers: Dr. Fred M. Dean, Jefferson, president; Dr. Geo. H. Grimmell, vice-president; Dr. George W. Kester, Grand Junction, secretary and treasurer, and Drs. J. Will Presnell, Scranton; Charles Enfield, Jefferson, and Fred. M. Dean, Jefferson, censors.

Kansas.

SMITH COUNTY MEDICAL SOCIETY.—This society was organized at Smith Center, November 16, as an auxiliary to the Kansas State Medical Society with the following officers: President, Dr. M. Francis Leary, Gaylord; vice-president, Dr. Bernard W. Slagle, Smith Center, and secretary-treasurer, Dr. Daniel W. Relihan, Smith Center. The society starts out with a membership of twelve.

Maryland.

CLARKE AND FREDERICK COUNTIES MEDICAL ASSOCIATION.—About fifty of the physicians of Frederick and Clarke counties have organized a medical society at Winchester with the following officers: Dr. William J. Best, Brucetown, president; Dr. P. Powell Page, Boyce, vice-president, and Dr. Samuel P. Latane, Winchester, secretary.

Book Notices.

A TEXT-BOOK OF THE PRACTICE OF MEDICINE. By James M. Anders, M.D., Ph.D., LL.D., Professor of the Practice of Medicine and of Clinical Medicine, Medico-Chirurgical College, Philadelphia. Sixth Edition, Thoroughly Revised. Fully Illustrated. Cloth. Pp. 1,300. Price, $5.50 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

Anders' book has become recognized as one of the most practical works on the practice of medicine in the English language and no better proof of this is wanted than the fact that six editions have been called for in as many years. This edition is not simply a reprint of the former ones, but is rewritten in many parts. Especially is this true of the paragraphs relating to the etiology of malarial fever, yellow fever, and other diseases of presumed parasitic origin. The majority of the chapters show evidence of revision and every subject is brought thoroughly up to date.

THE MICROSCOPICAL EXAMINATION OF FOODS AND DRUGS. A Practical Introduction to the Methods Adopted in the Microscopical Examination of Foods and Drugs, in the Entire, Crushed and Powdered States. By Henry George Greenish, F.I.C., F.L.S., Professor of Pharmaceutics to the Pharmaceutical Society of Great Britain. With 168 Illustrations. Cloth. Pp. 316. Price, $3.50 net. Philadelphia: P. Blakiston's Son & Co. 1903.

The author makes a plea for the more general use of the microscope in the detection of adulteration of foods and drugs in the powdered form. Directions are given for the detection of the different starches and textile fibers; certain drugs such as lycopodium, ergot, etc., woody substances, leaves, barks, seeds, fruits, etc., of various kinds. The directions for mounting, preparing and examining are sufficiently elementary and full to satisfy every one who understands how to use the microscope. The book is well illustrated.

ELEMENTS DE SEMEIOLOGIE INFANTILE. Par le Dr. Fernandes Figueira, ancien chef de clinique pediatrique a la Faculté de Médecine, Rio de Janeiro, Preface de M. Le Dr. Hutinel, Professor a la Faculté de Médecine de Paris. Avec 78 figures dans le texte. Cloth. Pp. 632. Paris: Octave Doin, Editeur. 1903.

This work will fill a useful place in the hands of the practitioner who reads the language in which it appears. Though written by a Brazilian physician it is published in France and is, therefore much more accessible, as there are comparatively few readers of the Portuguese language. The author has brought together with much industry the principal symp-

tomatology and arranged it in a natural classification so that any particular symptom can be readily found. The book is fully illustrated and the cuts are generally good and instructive. Each chapter has attached to it a bibliography, and while we think more American authorities might have been quoted with advantage, nevertheless it shows that the author's reading has been very extensive and that he has taken his facts from all sources.

PHYSIOLOGICAL ASPECTS OF THE LIQUOR PROBLEM. Investigations Made by and Under the Direction of W. O. Atwater, John S. Billings, H. P. Bowditch, R. H. Chittenden and W. H. Welch, Sub-Committee of the Committee of Fifty to Investigate the Liquor Problem. Vols. I and II. Cloth. Pp. 396 and 379 Respectively. Price, $4.50 net Per Set. Boston and New York: Houghton, Mifflin & Co. 1903.

The alcohol question is one of the living issues of the day—a statement that can not be denied, whichever side of the question one may take. These two volumes form a valuable contribution to the literature of the subject and contain the testimony of perhaps the most competent experts on the various phases of the question. The general report of the subcommittee of the committee of fifty, consisting of Drs. J. S. Billings, W. O. Atwater, H. P. Bowditch, R. H. Chittenden and W. H. Welch, sums up the conclusions which were deduced from the various investigations reported elsewhere in the works. The rest of the two volumes is made up of separate reports on instruction in the physiologic action of alcohol, the effect of alcohol on digestion and secretion, the effects of the use of alcoholic drinks on brain workers and the relation of drink habits to insanity, the influence of alcohol on growth, the pharmacologic action of ethyl alcohol, the nutritive value of alcohol and its pathologic effects. The report on physiologic instruction gives the results of an inquiry by Drs. Bowditch and Hodge, who notice the opinions expressed in the text-books of this country and Europe and criticise the instruction manuals endorsed by the Woman's Christian Temperance Union for primary and grammar schools, giving also the answers of public school teachers as to their opinions as to the fitness and value of these works and the instruction they convey. The opinions expressed are naturally various, both those of physiologic experts as well as those of school teachers, and the condemnation, by some, of the text-books approved by the Woman's Christian Temperance Union is rather severe. We regret that the tone of this report is not a little more judicial. The report concludes with a summary of the state laws on physiologic instruction in regard to alcohol. The report on digestion and secretion by Dr. Chittenden is lengthy and complete, and may be taken as a very fair critical summary of our present knowledge of the subject as well as containing valuable original data. The data relating to the use of alcoholic drinks among brain workers and the relation of the drink habit to insanity are less valuable, it appears to us, as compared with certain other of the memoirs. The first consists mainly of the testimony of individuals and is, therefore, not entirely free from the possibilities of individual preferences or prejudices. That on the relation of the drink habit to insanity is necessarily incomplete and the statistics that can be obtained meeting all the requirements are rather limited. Dr. Hodge's memoir on the influence of alcohol on growth is interesting as well as that on the influence of alcohol on normal vital resistance of rabbits to infection. The experiments were naturally carried out on the lower animals, such as dogs and rabbits, and the facts are not necessarily applicable to the human species; still they are significant and interesting so far as they go. Perhaps the most valuable portion of the work is contained in the two principal memoirs of the second volume, namely, those on the pharmacologic action of ethyl alcohol, by Professor Abel, and on the nutritive value of alcohol, by Professor W. O. Atwater. Both of these are worthy of study by temperance workers and others. Considering the fact that Professor Atwater's assertion that alcohol as a food value has been largely utilized in some quarters, it is of interest to consider certain statements in which he speaks of alcohol as at best a very expensive sort of nutriment in healthy people and only valuable when the user is unable from disability or disease to obtain sufficient nourishment from ordinary food materials. The concluding passage reads as follows: "The reason for emphasizing these facts is that any statement which compares the nutritive value of alcohol with that of ordinary food is in danger of being used by interested persons or those who are inclined to self-indulgence without the quality needed to work out the whole truth." The memoir on the pathologic effects of alcohol by Welch, though short, is excellent, and the Woman's Christian Temperance Union can derive all the arguments that it really needs from its statements. We believe the two volumes will serve a very useful purpose, and be in every way a sort of landmark in the discussion of the alcohol question. As to the general conclusions of the committee, which condemn—or perhaps to use a less emphatic term, discourage—systematic instruction of children in the primary schools on the subject of alcohol, there will, of course, always be a certain amount of difference of opinion. The question whether it is better to instruct young children as to the evil of alcohol or wait until they are older is perhaps one that teachers can decide better than we. What is said, however, about the teaching of specially isolated matter now being overdone is correct. It is important that what is told should be within the range of accepted probability, if not absolutely of demonstrated fact, and too much zeal has overdone the temperance instruction. The fact that quite a number of foreign physiologists to whom we owe a large part of our knowledge on the subject signed with reservations the statement by Sir Michael Foster which was sent them, is a matter of some little moment. It is unfortunate that there is so much difference of opinion on the subject, though the reading of this report and its contained papers shows that as regards the main points the authorities agree on the principal facts.

Society Proceedings.

COMING MEETINGS.

Southern Surgical and Gynecological Association, Birmingham, Ala., Dec. 15.

Western Surgical and Gynecological Association, Denver, Dec. 28-29.

NORTHWEST MEDICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Oct. 6, 1903.

Dr. A. C. Buckley in the Chair.

Pneumonia with Hemiplegia.

DR. HARRY LOWENBURG reported a case of lobar pneumonia with delayed resolution but recovery, complicated by hemiplegia with partial recovery.

DR. LUTHER C. PETER referred to the fact that hemiplegia occurs considerably in the infectious fevers, particularly typhoid, coming on usually during convalescence, when the circulation is exceedingly slow, and being usually due to a thrombosis. In the case described, however, he felt that the sudden onset pointed to an embolism.

DRS. M. P. WARMUTH and A. C. BUCKLEY reported cases.

A Case of Ludwig's Angina.

DR. C. M. HARRIS described this disease: A streptococcus infection about the submaxillary gland and alveolar tissue beneath the mucous membrane in the floor of the mouth, with cellulitis tending to sloughing rather than to pus. Symptoms: Local discomfort followed in from two to four days by swelling and pain, pressure causing considerable dysphagia and sometimes salivation and dyspnea; in some, septicemia or gangrene. Treatment: Prompt incision and removal of any gangrenous tissue, application of carbolic acid, constitutional treatment for septicemia. He reported a case: A patient remained in a public bath two or three hours; the following day there was pain in the right ear and swelling in the right submaxillary region. The symptoms increased, a hard tense swelling unattended by external redness or any heat developed, and on the fifth day began to diminish; on the seventh day disappeared, and the mouth could then be opened; on the ninth day pus was discharged from the affected ear; this continued for about a week, when it ceased and the patient has since enjoyed good health. The constitutional treatment consisted of ¼-

grain doses of calomel hourly for eight to ten hours during the first four days of the disease, and local applications of peroxid of hydrogen and other antiseptic solutions.

DISCUSSION.

DR. JUSTUS SINEXON reported a case of cervical cellulitis in an engineer. He was given 1/10-grain doses of calomel every hour for four or five days. On the fifth day an incision was made in the floor of the mouth without any result, which after the application of a belladonna ointment was followed by the discharge of a small amount of pus and the man made a good recovery.

DR. WILLIAM L. PEPPER referred to the frequency of the occurrence of cellulitis during epidemics of influenza, as well as in cases of peridentitis, which he ascribed to the infection traveling through the glands.

DR. T. TURNER THOMAS reported a case in which the incision had been made on about the seventh or eighth day of the disease, followed by hot applications of bichlorid. The patient had considerable dyspnea, which was increased after the operation, and during a severe attack a tracheotomy was attempted, but before it was performed the patient died. He felt that the danger in this condition was principally due to the fact that it involved the deep structures, the least resistance being in the direction of the mouth and throat. He recommended the employment of early free incision, and believed that the prognosis was also dependent on the kind of infection.

DR. HARRIS said that there was probably some danger in the conservative treatment, and that radical measures were probably the surest means.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Nov. 5, 1903.

The President, Andrew H. Smith, M.D., in the Chair.

Eye Lesions Occurring in Diseases of the Heart, Blood Vessels and Kidneys.

DR. CHARLES STEDMAN BULL presented this paper, and said that with obstruction to the return circulation a venous hyperemia of the retina is usually seen; in aortic insufficiency alternate reddening and blanching of the optic disc, frequently; in advanced heart disease, retinal pulsation, almost constantly; in fatty heart, as also in syphilitic, nephritic or diabetic degeneration of the blood vessels, numerous retinal hemorrhages, commonly. Thrombosis and embolism are common accompaniments of rheumatic endocarditis. Emboli of the choroid does not cause marked symptoms, but an embolism of the central trunk of the retinal artery causes sudden blindness, which is, with few exceptions, permanent. Occasionally a collateral circulation is established; this is favored by massage of the eyeball.

The most frequent lesions associated with disease of the kidneys are in the retina and optic nerve: (1) Degenerative inflammation of the retina with hemorrhages and whitish patches, and (2) an exudative inflammation, occurring with parenchymatous nephritis, and distinguished by whitish patches arranged in a stellate manner around the macula lutea, and usually accompanied by retinal hemorrhages and edema of the optic disc and surrounding retina. The disease is always bilateral, though it may appear in one eye before the other is affected. Retinitis albuminurica must be regarded as one of the terminal lesions of nephritis.

DISCUSSION.

DR. FRANCIS P. KINNICUTT said that amaurosis might occur in renal disease without the usual symptoms of nephritis. In some cases retinal changes are rather an indication of general vascular disease than truly albuminuric. With a well-marked retinitis and a history of chronic nephritis and of arterial disease death is probable in two years in hospital practice; but in private practice the prognosis is better.

DR. WARD A. HOLDEN considered the pathology of retinitis albuminurica, and the subject was further discussed by Drs. E. Gruening, J. W. Brannan and H. Knapp.

DR. THOMAS R. POOLEY said that too much stress should not be put on the occurrence of retinal pulsation, for, in a study of this subject in connection with heart disease, he had found it exceedingly difficult in many instances to detect any pulsation. He doubted very much if the ophthalmoscopic picture supposed to indicate embolism of the central artery of the retina was really dependent on this cause. In nearly all of the carefully observed cases a thrombosis had also been found. The typical appearance of Bright's neuroretinitis was not often seen; in many cases of granular kidney he had only observed petechial hemorrhages. As one of the earliest writers in this country who had advocated the induction of premature labor in cases of albuminuric retinitis, he wished again to enter a plea for such practice. If labor were induced early, it was probable that sight would be restored.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

To Kill Bedbugs.

A member writes asking the best way of disposing of bedbugs. He has been unsuccessful in his endeavor to assist some patients in getting rid of them by means of fumigations with sulphur and formaldehyd. He has also tried carbolic acid and bichlorid of mercury in the strength used in surgery, which have proved a failure. In answer to his inquiry we would suggest a strong solution of bichlorid of mercury in alcohol applied to the bed, the object being to leave a good deposit of the bichlorid after the alcohol has evaporated. We feel sure of his success if he will make the solution sufficiently strong. This could also be used with a syringe in the crevices about the room.

A Good Cough Syrup.

A subscriber recommends the following well-tried combination for the relief of the cough in bronchitis:

℞.	Codinæ sulph.	gr. iii	20
	Ammon. chloridi		
	Spts. chloroformi, āā	ʒiss	6
	Syr. tolutani		
	Ext. glycyrrhizæ flu., āā	ʒi	30
	Acidi hydrocyanici dil.	gtts. xv	1
	Aquæ q. s. ad	ʒiv	120

M. Sig.: One teaspoonful every four hours.

[This might be made more palatable by the omission of the glycyrrhiza or of the syrup of tolu, especially in cases with impaired digestion or appetite.]

High Arterial Tension.

According to an abstract in *N. Y. Med. Jour.*, M. Huchard lays but little stress on the value of the iodin preparations as reducers of arterial overtension. Iodin medication, however, is indicated when marked arteriosclerosis is present, in which case the resolvent action of the iodin preparations is explained by phagocytosis. In the period preceding sclerosis iodin preparations, according to the author, are valueless, and in their stead the essential vasodilators should be employed, such as amyl nitrite, trinitrine or sodium nitrite.

The following combination is recommended by him:

℞.	Sodii nitritis	gr. iii	20
	Pot. nitratis	gr. xv	1
	Sod. bicarb.	gr. xxx	2
	Aq. destil.	ʒii	60

M. Sig.: The entire mixture to be taken at one dose and repeated once or twice daily; or:

℞.	Sodii nitritis	gr. xxx	2
	Pot. nitratis	ʒiiss	10
	Sodii bicarb.	ʒv	20
	Aq. destil.	ʒx	300

M. Sig.: A dessertspoonful to a tablespoonful once or twice daily in half a glass of water. The advantages in the foregoing combination are that when the sodium nitrite is combined with the potassium nitrate and then rendered alkaline

with the sodium bicarbonate the sodium nitrite becomes less noxious and is of great value in lowering arterial tension, which remains low for some time after the preparation is discontinued.

Uremic Dyspnea.

The following method of producing profuse perspiration is recommended by *Jour. des Pract.* in the treatment of uremia:

℞. Pilocarpinæ nitratis .....gr. ¾ | 05
Vaselini .....ʒii 60 |

M. Sig.: To be rubbed into the chest and a bandage applied until profuse perspiration is produced.

A Tonic for Children.

Iodin, according to an abstract in *N. Y. and Phil. Med. Jour.*, is recommended as a tonic and alterative in poorly nourished children, combined as follows:

℞. Tinct. iodi .....gr. lxxv 5 |
Ext. catechu 3v 20
Alcoholis 3iiss 10
Glycerini .....ʒiii 90
Syr. idaei .....ʒvii 210 |

M. Sig.: One tablespoonful once or twice daily.

In rachitic children the following has been advised:

℞. Acidi calcii phos. .....gr. lxxv 5 |
Tinct. essentiæ anis 3iiss 10
Syr. simplicis .....ʒvi 180 |

M. Sig.: One tablespoonful every morning before breakfast.

Chapped Hands.

Brocq of Paris, according to an article in *Ther. Gazette*, recommends the following treatment for chapped hands:

℞. Glycerini .....ʒiss 45 |
Tinct. peru. .....ʒss 15
Sodii salicylatis 3i 4
Aq. lactucarii .....ʒvi 180 |

M. Sig.: Wash the hands with this solution twice daily; or:

℞. Acidi tannici .....gr. viiss | 50
Glycerini 3v 20
Aquæ rosæ .....ʒiii 90 |

M. Sig.: Apply locally to the hands.

And as an ointment one of the following combinations should be applied at night:

℞. Essentiæ rosæ .....gtt. i | 06
Vanillin .....gr. viiss | 50
Lanolini .....ʒiss 45 |

M. Ft. unguentum. Sig.: Apply locally at night; or:

℞. Menthol .....gr. xv 1 |
Salol .....gr. xxx 2
Olei olivæ 5iiss 10
Lanolini .....ʒiss 45 |

M. Ft. unguentum. Sig.: Apply locally at night.

La Grippe.

The following combination is recommended by *Rev. Francaise de Med. et de Chir.*, in the treatment of la grippe:

℞. Antipyrini .....gr. xxx 2 |
Sodii benzoatis .....gr. xxxvii 2 | 50
Aq. laurocerasi 3iiss 10
Syrupi codeinæ 3vi 24
Aquæ destil. .....ʒiii 90 |

M. Sig.: One to two tablespoonfuls every hour until the entire amount is taken.

The Vaginal Douche.

In giving directions for the use of the vaginal douche, F. B. Robinson, in *Ther. Gazette*, states that a fountain syringe holding fourteen quarts should be used, which can be made from such a sized pail to which a tube is properly attached. A siphon tube may be employed. The patient should be instructed to begin with two quarts at a temperature of 105 F. and increase the heat daily until it is as hot as can be borne, and at the same time increase the quantity one pint each day until the fourteen quarts are taken. The douche should be used twice a day, morning and evening, resting for at least three-quarters of an hour after the douche. It should require, according to the author, at least thirty minutes to take the douche of fourteen quarts. The patient while taking the douche should lie on her back with thighs flexed on the abdomen and legs flexed on the thighs. A handful of sodium chlorid and a teaspoonful of alum should be added to each gallon of water, the salt being used to dissolve the mucus and pus and the alum to act as an astringent, check waste secretions and harden the tissues. He condemns the use of carbolic acid as useless and the bichlorid of mercury as dangerous. Zinc and lead salts are not so valuable as alum as astringents, while mercurial salts, carbolic acid, boracic acid coagulate the discharge; however, the best disinfectants are carbolic acid and potassium permanganate. He recommends sodium sulphate as the best general solvent of the discharges, dissolving mucus, pus, leucocytes, etc. The best vaginal tube is the largest that can be conveniently used in order to distend the vaginal fornices and consequently allow the fluid to reach the upper end of the vagina. He employs a tube which is introduced in a closed state and expands after being so introduced. The value of the vaginal douche, according to the writer, consists in:

1. Contracting the muscle and connective tissue.
2. It contracts the lymphatics, veins and arteries.
3. It absorbs exudates.
4. It checks secretions.
5. It stimulates.
6. It relieves pain and cleanses the parts.
7. It checks hemorrhages and curtails inflammation and serves as a good drainage for the genital tract. Emphasis is also placed on the utility of the douche depending on the quantity, the temperature, its composition, the position of the patient and the systematic use. The douche, to be curative, should be continued for months.

Pains of Tabes and Neuritis.

Bouchard, in *Internat. Clinics*, recommends small doses of mercury and potassium iodid as a very efficient combination in the treatment of tabetic and neuritic pains combined as follows:

℞. Hydrarg. biniodidi .....gr. 1/6 | 01
Potassii iodidi 5i 4
Aquæ .....ʒiii 90 |

M. Sig.: Thirty drops to be injected locally about the seat of the pain.

The same treatment is also recommended in the obstinate late manifestations of syphilis. It aids in the rapid absorption of the gummatous lesion.

Chronic Eczema of the Scalp.

Shoemaker recommends the following combination in the treatment of chronic eczema of the scalp in children:

℞. Creosoti .....m. viii | 50
Hydrarg. chloridi mitis.
Camphoræ, āā .....gr. x | 65
Ung. zinci oxidi .....ʒss 15
Olei olivæ q. s. ad.....ʒiii 90 |

M. Sig.: Apply locally to the scalp once or twice daily.

Spasmodic Croup.

L. Boyer, in *Med. Rev. of Reviews*, recommends the following treatment of spasmodic croup:

℞. Hydrarg. chloridi mitis .....gr. iii | 20
Sacchari albi .....3ss 2 |

M. Ft. chart. No. viii. Sig.: One every two hours, alternating with the following:

℞. Apomorph. hydrochlor. .....gr. 1/6 | 01
Acidi hydrochlor. dil. .....m. ii | 12
Syr. simplicis .....3ii 8 |
Aq. destil. q. s. ad.....ʒiv 120 |

M. Sig.: One or two teaspoonfuls every two hours.

Syrup of the Iodid of Iron.

M. C. Hoge, in an article in the *Virg. Med. Semi-Monthly*, recommends the syrup of the iodid of iron in teaspoonful doses three times a day as an alterative. It acts as a diuretic and promotes secretions and produces an increase in the patient's weight. He advises it in the dry, rasping coughs and colds

where ordinarily codein and quinin are used improperly. He also employs it in the treatment of amenorrhea and dysmenorrhea in scrofulous women in half-teaspoonful doses three times a day. To anemic subjects suffering from rheumatic gout he administers it combined with pure cod liver oil.

Medicolegal.

Damages Allowed for Loss of Eyesight.—In the personal injury case of Vant Hul vs. the Great Northern Railway Company, where the party suing, a young man of 18 years, lost the entire vision of one eye, and, according to the testimony, the other eye was impaired to the extent of about nine-tenths, with a strong probability that the sight would ultimately be entirely lost, the Supreme Court of Minnesota holds that it could not be said that a verdict of $14,400 was excessive.

Seamen Entitled to Medical Care at Expense of Ship.—The Supreme Court of Washington says, in the personal injury case of Sanders vs. The Stimson Mill Company, that the authorities sustain the contention that under the maritime law a seaman who receives an injury while in the service of the ship is entitled to medical care, nursing and attendance, and to a cure, so far as is possible, at the expense of the ship, regardless of whether or not the condition of the seaman is brought about by the negligence of the owners of the ship, or is the result of disease or accident. But this does not go beyond expenses incurred in getting well. And it has been frequently decided that it makes no difference whether the medical attendance was on board the ship, or whether the party requiring the attendance had been removed to some other place. The action may be brought either in the federal or state courts. In the case of Holt vs. Cummings, 102 Pa. 212, the action was brought by the physician who waited on the disabled seaman, an engineer of a tugboat employed in the Delaware River.

Death from Appendicitis Caused by Bicycle Ride Not "Accidental."—The evidence of the party suing in the case of Appel vs. the Ætna Life Insurance Company tended to prove, what the Fourth Appellate Division of the Supreme Court of New York assumes for the purposes of the case, that the appendicitis which resulted in the death of the insured in this case was caused by a bicycle ride which he took. But the court declares that it can conceive of no theory on which it could be said, from the facts disclosed by the evidence, that the death of the insured resulted from "bodily injuries, effected . . . through external, violent and accidental means," within the meaning of the insurance policy sued on. The most, it states, that could be said was that the result was accidental, but the means which produced it were not accidental. The evidence wholly failed to show that the insured did anything which he did not fully intend to do, or that what he did was not precisely as intended; therefore, the result of such acts—his death—was not produced by "accidental means." The court's attention was not called to any case which holds, and it failed to discover any authority for the proposition, that a result which is produced by means all of which, and every detail of which, was intended, can be said to have been produced by accidental means, simply because the result which followed the employment of such means, exactly in the manner intended, was different from the result anticipated.

Failure to Use Tourniquet.—The Supreme Court of Pennsylvania says, in the malpractice case of De Long vs. Delaney, that the husband of the party suing had his leg badly crushed in attempting to board a railroad train and the party sued, a physician, was called in on the emergency to treat him. The physician rendered the first aids, washed and dressed the wound, bandaged the leg, and then relinquished the case to the family physician, who was expected, and arrived by the same train on which he (the first physician) left. The injured man remained under the care of the family physician for about two hours, and then was put on a train and taken to a hospital, where his leg was found to have bled profusely, and where he died a few hours later from loss of blood. At the trial the party suing proved the foregoing facts; gave some evidence that a tourniquet was an instrument in common use among physicians for stopping the flow of blood, and that it had not been used by the physician sued. She then rested her case, and the trial court entered a non-suit, which the Supreme Court holds was proper. It says that the negligence relied on was the failure to use a tourniquet. But there was no evidence at all, from any witness competent to express an opinion, that a tourniquet should have been used, or that the tight bandage applied by the physician sued was not fully equivalent—in short, that there was any negligence shown. The jury could only have made an uninformed guess. Negligence can not be found in that way.

Validity of Contract Not to Practice in Old Locality.—Two physicians practicing their profession at a certain place as partners entered into a written contract for the dissolution of the copartnership, one purchasing the property of the copartnership, and the other agreeing not to practice medicine in the vicinity of that place. Commenting generally, the Supreme Court of Oklahoma says, Hulen vs. Earel, that these contracts do not seem to be unusual. The books are full of such cases, and probably more of those between physicians than of any other profession or trade. They have been uniformly upheld by the courts of the several states, where they have not been controlled by statutory provision, and equity has always granted relief by injunction to restrain a breach, for the reason, principally, that the injury arising from such breach can not be estimated or repaired. A suit at law affords no adequate remedy, and, the damage being continuing, and accruing from day to day, the object of the contract can only be obtained by the parties to the contract conforming to its express terms. It is, therefore, very proper for a court of equity to enforce such a contract by granting an injunction to prevent a breach when it is within the rules laid down and within the rules of the controlling statute. One of the controlling features in all of the cases on this subject seems to be that, if such contracts are not upheld, the subject-matter would not be salable. But the court holds that this particular contract was in violation of the Oklahoma statute and invalid, although it says that it would have been an easy matter for the parties to have made a contract complying strictly with the provisions of the statute, one of which is that one who sells the good will of a business may agree to refrain from carrying on a similar business within a specified county, city or part thereof, so long as the buyer or person deriving title to the good will carries on a like business therein, whereas it will be observed the contract here was not to engage in the practice of medicine in the vicinity of a certain place, without any limitation.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.

November 14.

1 *Gonorrhea in Infants with a Report of Eight Cases of Pyemia. Reuel B. Kimball.
2 *Terminal Syphilis and Tabes. William J. Dougherty.
3 *Traumatic Separations of the Lower Epiphysis of the Humerus and Their Treatment by the Extended Position. With Report of Two Cases. Gilbert G. Cottam.
4 *Emulsion-Albuminuria. Isador H. Coriat.
5 Report of a Needle in the Prostatic Urethra. B. B. Foster.
6 A Case of Lead Osteoperiostitis. W. Moser.
7 Abdominal Pain in Pneumonia. Charles S. Grabin.

1. **Gonorrhea in Infants.**—From experience in the Babies' Hospital of New York, Kimball finds absolute isolation the only recourse in these cases. It might be possible to keep older children in the general ward, but with babies that have to be constantly handled this is impossible, and the utmost precautions are taken in his service to keep apart the clothing, wash cloths, thermometers, nursing bottles, etc. He sums up his conclusions in the following:

1. Gonorrhœa prevails among infants and children to an extent not fully appreciated by the medical profession at large, and has become a common epidemic in institutions where numbers of children are placed together.
2. The ordinary clinical forms which the gonococcus infection assumes in children are ophthalmia, vulvovaginitis and pyemia.
3. A series of cases of pyemia, reported in this paper, occurred in infants, in whom no local lesion could be found to explain the mode of entrance of the organism to the general circulation.
4. The suggestion is made that from a stomatitis due to the gonococcus such a systemic infection may arise. Gonorrheal stomatitis in infants is a disease that needs further study.
5. Only by careful exclusion, by microscopical examination and by complete isolation can this disease be absolutely debarred from a hospital where infants are cared for.
6. There is urgent need of public enlightenment on this subject. Those in charge of institutions for children, trained nurses and even parents, should be taught the frequency and virulency of this infection and the ease with which it is spread. It should be the duty of health authorities to include gonorrhea among the acute infectious diseases of children.

2. **Tabes.**—The arguments for and against the syphilitic origin of tabes are reviewed by Dougherty, who concludes that in the great majority of cases at least, if not in all, the weight of evidence favors the late or terminal action of syphilitic poison.

3. **Separation of the Lower Epiphysis of the Humerus.**—The views of the various authors for the treatment of this condition are reviewed by Cottam, who points out their disagreements and then gives his own experience with the extension treatment in 2 cases. They are the only ones he has treated without loss of function to some degree, and he therefore feels encouraged to use the extended position in future, despite the weight of authority against it.

4. **Emulsion-Albuminuria.**—Cramer's type of albuminuria in urine with a milky appearance which is due to some proteid substance in a peculiar physical state is noticed by Coriat, who reports a fourth case in addition to the 3 already on record. Like Cramer's cases, it ended fatally. His case was one of alcoholic delirium with coincident parenchymatous nephritis, with anxiety, fear, cyanosis and suppression of urine. As in the other cases, the milky appearance only showed itself a few days before death and negative tests afforded proof of the absence of neutral fat. All the proteid reactions were present. He thinks we have here a new and hitherto undescribed form of albuminuria in which the proteid exists not in simple solution, but in an emulsion or rather a peculiar colloidal physical state, apart and distinct from the ordinary ones and one which widens our conception of albuminuria.

12 *Operation in Hip-joint Disease Without Shortening. R. Preston Robinson.
13 *Gallstones and Gastric Hyperacidity. J. Kaufmann.
14 Human Terata. Austin O'Malley.

8. **Chronic Malaria.**—By chronic malaria Hemmeter understands a condition in which the malarial parasite is continuously present in the blood and which is clinically characterized by relapses of fever, splenic tumor and various complications. Among the complications he notices particularly those of the gastro-intestinal tract and the so-called typho-malaria, coincidence with dysentery, the complication involving the spleen and liver and splenomegaly or Banti's disease. Gastric ulcer may be produced by the malarial parasite, as asserted by Bignami, and it is natural to presume that the same organism may produce lesions in the colon and intestine. The complications on the part of the nervous system are those of mania, as described by Yanarris, hysteria and possibly neuroses. Occasionally paraplegia and hemiplegia complicate malarial fevers, as also meningitis, and both lobar and lobular pneumonia may occur as complications. There is a form of estivo-autumnal fever in which the symptoms are chiefly referred to the lung, and are identical with those of lobar pneumonia, though microscopic examination shows that the lesions present differ widely from the typical pneumonia lesions. The prognosis in these cases is often bad: always grave. Recovery is slow. Empyema may be a complication. Acute bronchitis is very frequent. Tuberculosis and malaria may occur simultaneously. Pleurisy and malaria are occasionally met with. Quinin does not invariably relieve these conditions, for some cases of chronic malaria are not relieved by quinin. Endocarditis may follow, and the ulcerative form occur. Functional diseases are very common. Nephritis is one of the most common complications, usually acute; it generally subsides after the cessation of the malarial attack. It is as much a consequence of malarial infection as it is a complication. Orchitis and epididymitis are rare, and usually have a history of gonorrhea.

9. See abstract in THE JOURNAL of October 17, p. 981.

10. **Migraine.**—Lichty calls attention to gastro-intestinal disturbances occurring with migraine, and says he has tried treating the disease on all the theories that have been evolved, but has fallen back on his old method of leaving off specific treatment, removing reflex and avoiding exciting causes. In many cases attempts at specific treatment have been not only useless but damaging. He remarks that there is no doubt that sodium salicylate has a decidedly beneficial effect. He thinks this is not due to its elimination of uric acid, but that it and calomel have a decided cholagogic effect and have the most efficacy as intestinal antiseptics and stimulants of bile secretion. By correcting the gastro-intestinal disturbance he has been able to reduce the frequency and severity of the attacks of migraine in many patients, sometimes completely curing them. He reports illustrative cases.

11. **Valvular Heart Disease with Tabes.**—The following are Stahl's conclusions:

1. Disease of some part of the circulatory system is present in nearly all cases of advanced tabes.
2. Valvular heart disease occurs in a large percentage of the cases.
3. The intimate relationship existing between syphilis and tabes and the pronounced circulatory changes induced by the former make it reasonable to regard syphilis as the cause of the large percentage of cases of valvular heart disease which we find associated with tabes.

12. **Hip-Joint Disease.**—Robinson reports and illustrates a case, and recommends the method of thoroughly clearing away all diseased bone and débris, carefully preserving the periosteum and stretching it along the track of the old bone and attaching it to the lower margin of the acetabulum. Then he stitches the muscles and fibrous tissue over the periosteum and stretches the leg full length, applying 15 to 20 pounds weight for extension. The wound is allowed to heal by granulation. The patient is instructed to sit up in bed two weeks after the operation and keep the weight on for four months, or a Thomas splint can be used and the patient allowed up after six weeks, but is not allowed to walk for six months. The results in the case that he reports have been excellent. The bone seems to have been reformed, and the limb is restored with comparatively no deformity.

13. **Gallstones and Gastric Hyperacidity.**—Kaufmann first notes Riedel's statement that 97 per cent. of gastralgic cases suffer from gallstones, and that the so-called cases of gastric ulcer reported cured by regular treatment were not cases of ulcer at all. If without hemorrhage, he considers them due to gallstones which have been set at rest for a time by treatment. Kaufmann follows this up with the statement that he considers the examination of the stomach contents absolutely necessary in all cases with pain in the upper abdomen, and that hyperacidity and hypersecretion are closely connected with the formation of gallstones; much more so than generally considered. In looking over the history of his cases he finds that the patients had previously complained of milder disturbances that were attributed to gastric hyperacidity. The subject is one of more than theoretic interest, as a correct interpretation of the condition is necessary to carry out proper treatment. Gallstones do not always require operation; internal treatment often subdues the irritation. When hyperacidity and hypersecretion make it probable that the mucosa of the stomach and of the duodenum is chronicly inflamed, we get the best results by lavage. Nothing acts better than the agents which favorably affect the inflamed

mucous membrane and other organs, such as solution of zinc and silver salts. By improving the chronic gastritis associated with hyperacidity and hypersecretion we may be able to prevent the formation of stones and set those already present at rest.

21 *The Operative Treatment of Chronic Bright's Disease; a Second Communication Based on Reports of 120 Cases. (Concluded.) Ramon Guiteras.

15. **Urinary Hyperacidity.**—In a former article Brown called attention to the symptoms which he attributes to this condition and which he thinks should be recognized as a cause of the syndrome simulating cystitis. If the acidity of the urine were tested in such cases an early diagnosis could be made and appropriate treatment adopted. Much unnecessary discomfort and pain would be spared the patient, beside the avoidance of the possibility of an erroneous diagnosis and inappropriate treatment. Two cases are reported.

16. **Antitoxin.**—Welden advocates the more frequent use of antitoxin in smaller doses. He has of late reduced the dose to 2,000 units and made the intervals between the injections shorter; that is, he uses it every three hours until there is a decrease in the severity of the symptoms. In this way we can keep the activity of the organisms under control. He reports one of his worst cases thus treated.

18. **Value of Egg Diet.**—The use of raw eggs in large quantities in the treatment of neurasthenia and fevers marked by high temperature and rapid waste, is advocated by Ely, who reports cases in which he gave from 12 to 24 raw eggs with up to a gallon of milk per diem. In a few cases some nausea, vomiting and diarrheal troubles followed, in which case he gave only the white of the eggs. He has given as many as forty-eight daily for many days to patients in critical stages of typhoid. They are useful for their supporting and restorative influence. Stimulants are correspondingly decreased. While he has had some patients die while taking eggs, he does not think death was due to their liberal use. He says in giving eggs we should not be chicken-hearted as to their quantity, nor fear albuminuria. In one typhoid patient with acute nephritis the albumin and casts vanished from the urine while thirty-six eggs a day were being taken. He advises a raw egg, swallowed whole every hour, in severe cases, and cites numerous instances of what he calls "the resurrection power of the egg."

21. **Chronic Nephritis.**—Guiteras' article is concluded in this number. He gives an extensive tabulation of cases, and ends with the following conclusions:

1. Chronic nephritis should not be operated on until medical treatment has proved of no avail.
2. The time for operation is when it is noticed that the process is advancing rapidly and we fear that the heart will soon become overtaxed.
3. The operation for chronic Bright's disease which has proved least dangerous and which has shown the best results, is nephropexy performed on a single movable kidney.
4. The most unfavorable cases for operation are those of diffuse nephritis.
5. Cases of general anasarca with bad heart action should not be operated on; if the heart action is good an operation performed as a *dernier ressort* may give the patients a few extra months of life, provided they survive it.
6. Where there has been a marked destructive process in the kidneys as a result of a nephritis, the operation may relieve them for a number of weeks or months, but they generally fail again and die when the new capsule begins to contract.

24 *Routine Treatment in a Genito-urinary Clinic; Functions of Such a Clinic. F. J. Cotton and R. F. O'Neil.
25 Some Principles Involved in the Therapeutic Applications of Radioactivity. William Rollins.

22. **Nursing Problems.**—Mumford's address is in its way interesting as not being exactly of the ordinary type of such addresses. He calls attention to the trials nurses are likely to experience, the lack of progress which is one of the drawbacks of the nursing profession, the mistake of starting in as special nurses, the ethical desirability of making concessions to the poor and especially to those of the middle class whose resources are limited but who are not exactly charity patients, the avoidance of Chauvinism, that is, the setting up of themselves as better than their sisters from other institutions; the choice of work, the probabilities of marriage, and the consequent curtailment of duties of the nursing profession as a life-work, etc. He advises nurses to cultivate some hobby outside of their profession to keep themselves broader-minded and more in touch with the outside world, neglecting, of course, none of their hygienic or their nursing duties.

23. **Digestive Disorders and Affections of the Air Passages.**—Robinson calls attention to the association of digestive and intestinal disturbances with affections of the nose and throat and the possibility of relieving the latter by attention to the former.

24. **The Genito-Urinary Clinic.**—The methods and experiences of the genito-urinary department of the Boston Dispensary are first described by Cotton and O'Neil, as well as their routine methods. They advise the use of strong carbolic acid, followed by alcohol in chancroids, subsequent instructing the patient to remove the scabs at each of the frequent home dressings. A thoroughly drained wound of this kind will rarely give rise to serious glandular complications, as their experience has shown. As regard urethral infection, they believe that the best treatment in all acute anterior gonorrheas is with copious and frequent irrigations combined in favorable cases with the use of protargol and other silver germicides. Later in the disease, astringent irrigations, medication by the endoscope and graduated stretching have their place. Posterior infections do best under not too frequent local treatment, begun only after the stormy stage is past. In the second part of their article they discuss the question of the routine treatment of gonorrhea and its value, the education of the patient and the public, protection of the patient's family and of the public, the education of the practitioner, student, etc. They believe it would be for the best interests of all concerned that a special genito-urinary clinic should treat cases of gonorrhea only under such conditions as are, in the surgeon's judgment, consistent with appropriate treatment and good results, refusing to help those who will not co-operate loyally in the treatment. The difficulty of keeping the patients under treatment is very great.

29 *Why Not Absolute Precision in Chyme Analysis? Mark I. Knapp.
30 *Precipitins and Their Medicolegal Use. (Continued.) James Ewing and Israel Strauss.

26. **Chronic Villous Arthritis.**—Painter and Erving's article is mainly a report of cases. Their view is that many of these conditions considered as tumors or lipomata are really degenerated villi, but they give rise to rather different symptoms than the ordinary synovial fringe. (The article is to be continued.)

27. **Tapeworm.**—The various remedies employed for tapeworm, such as male fern, kousso, pomegranate, turpentine, kamala, pumpkin seed, etc., are noticed by Gerhard, who finds the combination of male fern and pelletierine the most suitable. There is no necessity for the patient to make several days' preparation. The loss of one meal, breakfast, is all that is required. The patient is instructed to clear out the bowels the day previous with one or two large doses of castor oil or salts. One dose may be given in the morning and one at night, an hour or so after a light supper. The next morning as early as possible—say at 6 o'clock—give a dose of

pelletierine tannate, 20 gr., in two capsules. When this has operated freely, in about two or three hours begin with the following:

℞. Olii resinæ aspidii.....3ii
Aetheris.....3ii
Hydrargyri chloridii mitis.....gr. xii
M. et div. in capsulæ No. xvi. Sig.: Two every ten minutes.

Of course, no food is taken during this time. In two or three hours the worm will be expelled whole with the head. It is well to instruct the patient to pass all bowel movements into a vessel of warm water. No traction on the protruding worm should be permitted. The patient can then rest, and if there is any depression light food can be given.

29. **Chyme Analysis.**—The points emphasized in Knapp's paper are stated in the beginning as: (1) No better indicator is known for free HCl than supersaturated alcoholic solution of tropeolin 00. (2) That the dimethylamidoazobenzol as an indicator for only free HCl acid in chyme is absolutely wrong and misleading, but that as it reacts also on very weak solutions of organic acids it can be used for the quantitative determination of such acids. (3) That by the successive use of tropeolin, dimethyl and phenolphthalein in the same specimen of chyme we can determine, quantitatively, free HCl, organic acids and general acidity. The tropeolin solution used is prepared by throwing into absolute or very strong alcohol an excess of the powder of tropeolin 00 and leaving it stand for two or three days, shaking it up a few times. It is a dark cherry-red color, resembling tincture of iodin. To 5 c.c. of filtered chyme are added two drops of the tropeolin solution. If free HCl is present the stomach contents are colored a purplish-red, the intensity depending on the quantity of HCl. The further technic is shown. His summary is given as follows:

I want to reassert that, while dimethyl reacts very sharply on free mineral acids, it also reacts on other very weak acids; it reacts on such degrees of acidities of acids other than hydrochloric acid as are absolutely within the bounds of even a subacid stomach. That the supersaturated alcoholic solution of tropeolin 00 stands in no way behind the reagents of Günzburg and Boas, but that it has the additional advantage over these, inasmuch as it can be used for titration, and this with absolute precision. That both free hydrochloric acid and organic acids very, very often exist simultaneously, in the same chyme; that the presence of free hydrochloric acid does not negate the additional presence of organic acids, but that the presence of relatively large quantities of organic acids are abnormal and produce symptoms; that the presence of relatively large quantities of organic acids, either introduced into or formed within the stomach, gives the symptom-complex described by me as "Organacidia Gastrica" [See THE JOURNAL, Sept. 20, 1902, page 719]. That the presence of organic acids can and should be tested for by my direct method—described by me as the floating test—a test very easily carried out in about a minute or two. That free hydrochloric acid, organic acid and the general acidity can be determined (and this has always been done by me) in one and the same specimen, thus enabling us to work with very small quantities and also to save time.

The floating test above alluded to consists in taking 1 c.c. of filtered chyme and 1 c.c. of ether and shaking them up to extract the organic acid. One drop of a 10 per cent. solution of the ferrichlorid is added to 2 c.c. of distilled water in a narrow test tube and on it is floated the clear ether extract. At the plane of junction of the ether with the iron solution a colored ring appears which varies with the different acids, as described in his original article. Care should be taken that only the clear ether extract is floated.

30. **Precipitins.**—Ewing and Strauss' article is continued. In this issue they give mainly the method and technic.

41 Epidemic Influenza—A Historical Sketch. Q. W. Hunter.

35. **Should the Tuberculous Lung Be "Exercised"?**—Bridge argues against lung gymnastics in tuberculosis, claiming that quiescence of the diseased lung is desirable for the sake of its healing. He thinks it is impossible to demonstrate benefit from lung gymnastics in tuberculosis.

36. **Buccal Expressions of Constitutional States.**—The conditions noted by Talbot are pyorrhea alveolaris, dental caries, gingivitis, etc., that occur in connection with diabetes and other conditions. The condition of the mouth is an index of the general health. The toxins generated in the mouth rapidly pass into the general system and also produce their bad effects in that way. Neurasthenia may entail a predisposition to interstitial gingivitis, as he has shown, and it in turn aggravates the original condition.

37.—See abstract in THE JOURNAL of October 24, p. 1041.

39.—Ibid.

40. **Congenital Malformations.**—Pearl has studied the mortality returns of the last Census for the sake of determining the fact as to the frequency of congenital malformations in the two sexes, and draws the following conclusions:

1. The mean age at death from fatal congenital malformations of the sorts included under title No. 150, of the International Classification of Causes of Death, is essentially the same in men and women. Hence it may safely be concluded that the mean intensity or degree of the malformations is not essentially greater in one sex than in the other. 2. The variations in the age at death from such malformations, as measured by the standard deviation and the coefficient of variation, is significantly greater in women than in men, and hence we may conclude that in intensity or degree of the malformations woman is more variable than man.

He thinks it is impossible to formulate any general rule that either sex is more variable than the other in the human species.

47 *The Effect of Anesthesia on the Body Temperature. W. H. Morley.
48 Congenital Dislocations of the Hip Reduced by Forceful Manipulations. Angus McLean.

42. **The X-Ray.**—Breakey believes that the use of the *x*-ray is specially indicated in malignant disease where excision is impracticable. It should be employed after thorough curetting and removal of all crusted masses and of epitheliomatous growth on the floor of the ulcer and under the everted roll of border of rodent ulcer and all unhealthy granulations. This can be done under cocain anesthesia. Then after checking all hemorrhage and the application of a suitable chemical cautery, for which he usually prefers nitric, carbolic or pyrogallic acid, and the separation of the slight slough and beginning of granulation, the time has come when the conditions are most favorable for the therapeutic action of the *x*-ray. The occasional repetition of slight curetting or cauterization may be required. The use of the ray does not exclude other appropriate treatment.

43. **Adenoids.**—Hypertrophies of the "lymphoid ring," the faucial, pharyngeal and lingual tonsils, are considered by Shurly as causes of a large amount of the pathologic conditions and as entering points for infections. Chronic inflammations of these lymphoid tissues are of several varieties, such as the chronic lacunar, caseous or follicular inflammation of some authors, the chronic parenchymatous or the familiar enlarged tonsils. Polypoid hypertrophy is comparatively rare. There are many enlarged tonsils that are normal in structure and require no attention. Palliative methods, he thinks, as a rule, should be discouraged. Internal medication in the form of iodid of iron and hypophosphites is often exceedingly valuable. The question of hemorrhage must influence our choice of method and, therefore, the snare operation has many advocates. Sometimes ligation of the external carotid is re-

quired to stop the hemorrhage after other means of control have failed. The choice of the anesthetic is important. Nitrous oxid is usually enough, but may be supplemented by ether if necessary. Cocain infiltration is often very useful in office work. Objection to removal of the tonsils is sometimes made because singing teachers say it ruins the voice, and the laity believe this. Their complete removal may be followed by a temporary loss of the singing voice, especially several notes of the upper register, but this is due to the changed muscular movement of the pharynx. Where the operation is successfully performed and no ragged surfaces remain ,the voice is restored. Enlarged tonsils cause vocal fatigue and acute inflammation. He speaks well of the general plan of clearing out adenoid vegetation of the pharyngeal tonsil, and insists in conclusion on the danger that these structures involve as regard the development of infectious disease, diphtheria, scarlet fever, etc.

44. **Floating Kidney.**—Attridge describes the condition and its treatment, and concludes that nephropexy has not generally met with favor because of the number of relapses which are due to insufficient fibrous union between the kidney and the lumbar muscle. Further, that Edebohls' operation produces as nearly perfect results as is possible by any other method known to the writer.

46. **Fractured Spine.**—This article was noticed editorially last week. Rodi says considering the hopelessness of spinal fractures, almost any risk is justifiable, and we should operate in every case, seeing that we may possibly do some good and certainly, if proper antiseptic precautions be taken, we can do no harm. When traumatism of the spine is associated with paraplegia an operation is indicated to determine whether the paralysis is not due to bony pressure incapable of spontaneous relief. The operation should be deferred no longer than the recovery from the original shock demands. The earlier it is done the easier it is to reduce displacements and remove the broken pieces of bone.

47. **Anesthesia.**—Morley has investigated the effect of anesthesia on the body temperature, and gives the results of temperature studies of 46 patients operated on, showing the curves. From his study of previous work and his own observations he concludes that ether anesthesia lowers the body temperature on account of the increased heat output through the dilated vessels and the lessened heat produced from diminished muscular action. Stringent precautions are required to keep the body from losing heat during the operation by having the patient well protected with lint and bandages and by having a warm operating room. Many of the so-called post-operative pneumonias are due to the chilling the patient gets under anesthesia.

57 Papilloma of the Cornea. David H. Coover.

49. **Idiopathic Myositis of the Extraocular Muscles.**—In the case here reported by Gleason there was an acute idiopathic interstitial myositis of the superior rectus which produced exophthalmos and irritation demanding enucleation of the eye. An examination showed that this muscle alone was involved, and the only cause that could be determined was rheumatism. The case is of interest as showing that idiopathic myositis may occur in the ocular muscles.

51. **Ophthalmologic Terms.**—Suter disagrees with Suker (see JOURNAL, September 26, p. 811) as to the use of the terms anisometropia and antimetropia, as well as those of brachymetropia, hypometropia and myopia.

59 Multiple Angiomata. Abner Post.
60 A Case of Creeping Eruption (Lee), Larva Migrans (Crocker), Hyponomoderma (Kaposi). Henry W. Stelwagon.

58. **Paludides.**—This term, borrowed from the French, is used by Engman to designate the eruptions associated with malaria, among the more frequent of which is herpes simplex. He thinks the herpetic lesions from this cause are more severe and painful than from others. The febrile form with general malarial symptoms is familiar to every one. The non-febrile type is especially noted. Herpes zoster has often been associated with malaria in connection with pompholix, which he considers a vasomotor disturbance of toxic origin. Urticaria is, according to Thayer and others, the most frequent eruption in malaria, and there are three types: that accompanying the malarial paroxysm and usually appearing during the febrile stage; that replacing the chill, the other features of the paroxysm remaining; that taking the place of not only the chill but of the entire paroxysm. The latter class is the one most frequently seen by the dermatologist. There is nothing peculiar or characteristic about this except its periodicity and evanescence. Erythema multiforme has been observed by Engman, and other authors have also noticed similar cases. Malarial infection is often complicated by kidney lesions and albuminuria with casts which, when an eruption is present, may lead to an erroneous diagnosis of both the skin lesions and underlying condition. Several of Engman's cases have had a marked nephritis which cleared up under antipaludal treatment. Eczema in its different forms is noticed. Purpuric eruptions, while rare, are sometimes observed. His own experience with them is limited to 2 cases which he reports. Ulceration and gangrene of the skin, associated with malaria, particularly of the estivo-autumnal type, have been reported by several authorities besides the author.

65 *Squint and Its Modern Treatment. F. Park Lewis.

65. **Squint.**—Lewis argues for the early recognition and correction of squint and the use of glasses as soon as they can be worn. Fusion training should be at once employed under the direction of the surgeon to correct incipient amblyopia before the defect becomes fixed. Surgical intervention should be undertaken as soon as its necessity becomes established, and should consist of tenotomy or advancement, or both, at such time as will permit of perfect fusion if the correction by glasses and training does not suffice.

67. **Uncinariasis in Texas.**—Smith reports cases as he has observed them in students and gives a history of the disease since its discovery in this country.

68. **Uncinariasis in the United States Army.**—The same subject is taken up by Craig, who reports his military cases and analyzes the symptoms. He thinks the most important means of infection is by swallowing the worms, but attributes considerable importance to infection through the skin.

69. **Tuberculosis of the Tonsils.**—Cases are reported by Koplik illustrating infection of the tonsils by tubercle germs, showing that the tonsil is a seat of primary tuberculosis, though rarely as compared to the pyogenic forms of infection. The tubercular tissue appears in the form of giant cells and tubercular nodules; cheesy degeneration is not common. It is exceptional to find the tubercle bacilli abundant. Tubercular ulcerations are rare; as a rule, the lymph nodes leading from the tonsil are affected. Some of these tonsillar affections have been preceded by a simple catarrhal or diphtherial inflammation, and the tonsillar infection may be the source of the general tuberculosis. As far as tuberculosis of the cervical lymph nodes is concerned, when found isolated and of a primary nature, it can be justifiably claimed that the infection proceeded from the tonsil.

70. **Nasal Polypi.**—Packard found from his studies that nasal polypi are probably symptoms of underlying conditions, not tumors; that they are based on the existence of diseased bone, and if the latter is removed they do not reappear.

71. **Laryngeal Tuberculosis.**—The form of hypertrophic or hyperplastic laryngeal tuberculosis, of which a case is reported by Theisen, is considered by him as a distinct and unusual form of the disease. As a rule, there is no ulceration, but there may be some occurring later. It may be present at the same time as the hyperplasia of the tissues in some part of the larynx, but the characteristic circumscribed hypertrophies and tumor formations do not break down. It is practically always secondary to the pulmonary involvement, though there appears some evidence that it may occur as a primary affection.

81 Skiascopy in Refraction. F. W. Kettlestrings.
82 *On the Therapeutic Value of Bloodletting with a Report of Cases. G. B. Hassin.

82. **Blood-Letting.**—Hassin refers to the teachings of Botkin and Zakharin as regards blood-letting, pointing out where it may be of value as a revulsive measure. He considers Reyburn's paper in THE JOURNAL of June 6, 1903, as an important article on a subject which he thinks is too much neglected in modern practice. He reports 3 cases which illustrate the great value of venesection in the relief of hemorrhoids with periodic bleeding, in cerebral congestion and in a complication of symptoms associated with hemorrhoids which he diagnosed as hyperemia of the spinal meninges. He remarks that in Russia even at the present time there are people who are accustomed to being periodically bled by barbers and others.

83 *The Most Rational Method of Operation for Hemorrhoids. Emil Ries.
84 *The Dispensing Problem. Walter J. Wilson, Jr.
85 A Daily Study of Foods Producing or Not Producing Casts, Fatty Epithelia and Albumin in Urine. (Continued.) Ephraim Cutter.

83. **Hemorrhoids.**—The operation by the clamp and cautery is criticised by Ries as being imperfect and tedious, painful and predisposing to infection. The ideal method should lead to primary union, be applicable in all combinations of hemorrhoids, should preserve the natural configuration and function, and insure quick and safe recovery with little or no pain. The only method which meets all these indications in his opinion is excision and suture of hemorrhoids, not the Whitehead operation, but cutting out of the hemorrhoid in the longitudinal axis of the intestine and sewing it up with continuous catgut suture. He has used the method for external and internal piles, in all combinations, and there has been no difficulty in taking care of the inflamed as well as the non-inflamed piles. The line of excision and suture being always in the long axis of the bowel, there is no danger of subsequent stricture. The amount of mucous membrane and skin to be removed is absolutely under the control of the operator, and the shape and configuration of the anus can be perfectly preserved. A safe and quick recovery and absence of pain are proved by his description of the cases. He keeps the patient on a light diet and advises him to be careful as to sitting down; moves the bowels on the third morning after the operation and keeps up the regular bowel movements afterwards at least every second day. When the patient leaves on the sixth or seventh day he is instructed to see that the bowels move once a day, to take two tub-baths a day for one week and one bath a day after that, and to use wet cotton or a bath for toilet purposes instead of paper. He says whoever gives this method a fair trial can see to his own and his patient's pleasant surprise how well it works.

84. **The Dispensing Problem.**—The conclusions reached by Wilson are that physicians should prescribe nothing which they do not thoroughly know. The prescription should be put up by a qualified pharmacist who makes a specialty of such work. There should be an understanding between physicians and pharmacists that no repetition of prescriptions is permissible without the consent of the physician. A pharmacist should be found who does not sell patent medicines or at least does not push them, and who as far as possible keeps them out of sight. The pharmacists and physicians of every locality should have a joint meeting of their respective societies at least once a year to exchange ideas, and there should be a uniform practice regarding the dispensing of prescriptions.

87 Reports of Cases of, 1, Parasites in the Nasal Cavity; 2, Cockleburr in the Naso-pharynx of a Ten-Month-Old Child; 3, a Case of Anophthalmos. Oscar Dowling.
88 Hemophilia Complicated by Attacks of Multiform Erythema of the Hemorrhagic Type. T. H. Young.

86. **Apomorphin.**—A number of cases are reported by Bechet, who finds that strychnin counteracts the heart depression and the depression of respiration which follows the use of apomorphin in frequent doses, but that apomorphin acts as well in delirium tremens as in the other conditions of alcoholism, and is indicated in combating such a condition. It is better to begin with a small dose, about 1/30 gr. and increase it if necessary. In his case 1/15 gr. was the largest dose required.

89 *Food Adulteration: Its Nature and Extent, and How to Deal with It. Willis G. Tucker.

89. **Food Adulteration.**—Tucker, the director of the Bureau of Charity, New York State Department of Health, calls attention to the fact that food adulteration is not necessarily food poisoning. Much of the adulterated food is innocuous, and he goes over the various preparations pointing out that the great majority are fairly free from dangerous adulterants. Milk is often watered and preservatives added. Butter and cheese have been manipulated and sophisticated, but many of these evils have been checked. Canned goods are often poor in quality and preservatives have been used, but they are not necessarily bad from a sanitary point of view. He thinks that in this matter there is a disposition to respect the laws. Sophistication he thinks is little met with in the cereal foods, though some special foods like gluten breads and flour are not what they are claimed. Fresh vegetables and fruits are often sold in an unripe and rotten state, but that it not exactly adulteration. Sugars are generally pure. Jams, jellies and marmalades are often fictitious mixtures compounded with glucose, gelatin and artificial flavors, but not always necessarily unwholesome, and the purchaser can generally tell what he is getting. Tea and coffee are fairly pure. Chicory is often added to ground coffee, but generally in response to a demand rather than as an adulterant. When sold unground,

coffee is reliable. Spices, however, are quite generally adulterated. While the substances employed are usually harmless the practice is one that should not be condoned. Flavoring extracts are also adulterated, as are olive oil, vinegar, etc., but he says it is immaterial whether the vinegar used is made from cider, malt or whiskey. The dilute acetic acid of the U. S. P. containing 6 per cent. of absolute acid would perhaps be preferable to anything else, and Dr. Squibb once informed him that he used it in preference to vinegar on his own table. He mentions at some length the adulteration of liquors, and in conclusion makes some suggestions in regard to legislation. He thinks unnecessary legislation should be discouraged. We should set our own standards. We should endeavor to define articles precisely in framing food laws, and prescribe definite standards of quality or purity. This may be difficult, but often is quite practicable. There are very few articles employed in foods which should be absolutely prohibited; for example, he does not think the use of boric, benzoic and salicylic acid should be prohibited, but the articles in which they are employed should be labeled and the facts stated. The proper and honest labeling of all foods should be demanded and encouraged by the law. He thinks there is much more commercial honesty in the world than was formerly the case, and things are better than they were.

93 *A New Treatment of Dysmenorrhea. Emil Ries.
94 Report of Three Cases of Intussusception in Children. R. E. Skeel.

90. Tuberculosis of the Uterus.—Tuberculosis of the uterus is not uncommon, but is most frequently confined to the body of the uterus. When it appears in the cervix it occurs in several forms; in the form of a cauliflower growth showing a tendency to bleed, which is frequently mistaken for carcinoma but is less friable. The absence of the finger-like lesions characteristic of carcinoma will help to distinguish it. Microscopic examination will decide the diagnosis. In the ulcerative form the ulceration is usually well defined with sharp, undermined edges, and the surrounding tissue may be normal or studded with miliary tubercles. The ulceration may be covered with grayish exudate of broken-down caseous material, as in the case here reported by Vineberg. The diagnosis was reached by him by exclusion, and was not shaken by the report that no tubercle bacilli were found in the exudate. Microscopic examination of fragments of the tissue confirmed the diagnosis. The vaginal portion in the third form is studded with miliary tubercles, as may also be the cervical mucosa, and tubercles may penetrate the whole surface of the cervical wall (Vassmer). This form is easy of diagnosis. Lastly, the tuberculous portion may be localized to the superficial epithelium of the glands, the latter being filled with masses containing numerous tubercle bacilli. This is the bacillary catarrh described by Schütt. In the great majority of cases the cervical disease is secondary to disease higher up, and the treatment will be subsidiary to the treatment of other lesions. In primary disease of the cervix, amputation may be all that is required, as in the case reported by Frank. Vineberg thinks that more cases of cervical tuberculosis will be observed as the attention of the profession is more directed to the subject.

92. Thrombosis of the Femoral Vein Following Laparotomy.—From a study of the literature and of the case here reported, Secord concludes that no single etiologic factor is alone responsible for the occurrence of this complication, and that the rôle of infection in otherwise non-infective cases does not appear to be of chief importance. The conditions of sudden decrease of pressure depending on the operation probably have an active influence. The treatment should be prophylactic, avoiding unnecessary injury, hemorrhage, or sudden decrease in tension, and having the wound area supported by firmly applied dressings. As far as he has been aware, there has been no mortality in the cases but the occurrence of pulmonary embolism in some warns us that a fatal termination is not impossible.

93. Dysmenorrhea.—Ries calls attention to the suggestions of Fliess as to the genital spots in the nose and their local treatment by cocain as a relief for dysmenorrhea. He thinks it would be advisable to make a series of experiments to determine the nodus and the value of the treatment: 1. Use the method according to Fliess, that is, touching up the genital spots; 2, the use of cocain in the pharynx; 3, the use of cocain on the areas outside the genital areas in the nose; 4, the use of some astringent solution instead of cocain, and 5, the use of plain water at body temperature. Of course, the patient must be ignorant of what solution is being used. He suggests, however, a suspicion as to one point, that is, the possible encouragement of the cocain habit, and asks for testimony of whose who have had chances of observation, as to whether this habit has been thus aroused or whether cocain habitués ever suffer severely from the dysmenorrhea without relief from the cocain habit.

99 A Unique Case of Hydrosalpinx. A. Palmer Dudley.

95. Injuries of the Spine.—Means reports a number of cases and sums up his conclusions that all spinal injuries, no matter how slight, should be carefully examined at first sight, and owing to the frequency of secondary developments a guarded prognosis should be given. There are no positive signs of complete severance of the cord in the primary stage of an accident. The treatment of spinal injuries other than operative consists, first, in rest in the horizontal position, application of cold, attention to the bladder and rectum, and, second, in massage, galvanism and stimulating solutions. Laminectomy performed after reaction from shock is not dangerous, and is the only rational treatment for pressure on the cord from a blood clot or a bone depression. Relief may often follow operation several months after the inception of injury.

102. Venesection.—Wahrer considers that venesection has its value and that those who are not afraid to face popular prejudice against it will meet with success when they employ it in properly selected cases. He reports a number of cases showing its utility. Certain cases, such as pneumonia, reflex hepatitis, congestive headaches, cerebral congestion, etc., are favorable for this treatment. He also mentions that in uterine congestion it is frequently useful as an adjunct. In dilated right heart and pulmonary congestion, eclampsia with high arterial tension, pulmonary emphysema and some cases of thoracic aneurism, iritis of the plethoric, in uremia with acute renal congestion, and especially maniacal uremia, as well as in the acute nephrites of the robust, bleeding is almost always useful. It is also of value sometimes in stout people in reducing a dislocation and rendering it possible when otherwise impracticable. Its action, he thinks, is chiefly mechanical. It should not be used as a routine measure, but its indications depend on the knowledge of the pathologic processes present.

104. The Liquor Problem.—The report of the committee of fifty on the physiologic aspects of the liquor problem, which has been noticed elsewhere, is severely criticised by Irwell. He accuses the compilers of using an antiquated authority because it specially emphasizes the food value of alcohol. He also criticises Dr. Atwater's work, which he thinks is

based on his "fad" of accepting oxidation as a test of food value. He considers the W. C. T. U. methods condemnable, but that does not excuse the method of handling the subject by the committee of fifty.

172. **Abdominal Wounds.**—Brown advocates prompt operative interference in these cases, notwithstanding the unfavorable experience in military surgery. At the St. Louis City Hospital the practice is to immediately prepare for laparotomy, enlarge the wound of entrance, and track the bullet with the sterile finger. The probe is never used except to complete investigation. Brown has repeatedly seen symptoms point to perforation, and has not found it on operation, and vice versa. There is only one safe course. The hydrogen gas test of Senn he considers not safe, as when it is used in case of perforation fecal extravasation is bound to occur. The extent of injury done by a bullet can never be determined until the abdominal contents have been thoroughly gone over. In stab wounds the location of the wound should govern us, both as regards the length and situation of the abdominal opening. The importance of a systematic search is emphasized, as to close some perforations and not all would defeat the whole object. Brown is a believer in the virtue of irrigation and drainage in the treatment of wounds of this character. He always uses normal saline solution with a flush tube and the funnel of Price to clean the cavity. The region of the liver, spleen, both iliac regions and pelvis are flushed until the fluid returns clear. This is as a rule done at the completion of the operation. In cases where shock is severe it is his custom to fill the pelvic cavity with salt solution as soon as the abdomen is opened; it is rapidly absorbed, and it is remarkable how quickly the pulse will respond. The greater part of the paper consists of accounts of individual cases.

3. **Tuberculosis of the Nervous System.**—Trevelyan's Bradshaw lecture enumerates the following as the principal forms of tuberculosis of the nervous system: Tuberculosis of the dura mater, tuberculous meningitis in its general and limited forms, tuberculous masses in the brain and cord, and possibly miliary tuberculosis of the brain itself. He thinks we can have tuberculous meningitis without the presence of tubercles, but proof is wanted. The limited meningitis described by French authorities consists of thickening with tubercle formation over a limited region, usually the motor cortex. It is said to occur in phthisis. Its symptoms vary from the ordinary tuberculous meningitis. Tuberculous areas in the brain are not infrequent; they were present in 33 of the 114 cases analyzed by him. In 15 they appeared to be but little antecedent to the existing meningitis. They were only seldom multiple, the largest number observed was four. They are usually well defined, shelling out with ease, and show little tendency to break down and still less to calcify. Tubercles of the spinal cord are not uncommon. A thorough examination in these cases almost invariably reveals an older focus somewhere else in the system; in only 6 of the 114 cases was this absent. In these the notes were incomplete. Direct infection through the nose is believed possible, as in Demme's case, and tuberculosis of the ear may extend; but the latter route is indirect, for the ear is usually infected through the lymphatics of the nasopharynx. In 28 of the 114 cases the lungs were normal. It has been proved that tubercle bacilli may pass through the lungs without leaving an obvious recognizable lesion. The joints and hips were affected in 23 cases, and in 4 the kidney was the seat of extensive tuberculous disease. Ordinary tuberculous peritonitis was noted in 8 cases and intestinal ulcer in 28. Records were incomplete as regards the relation of the lymphatics to tuberculous meningitis. Trevelyan remarks that the mobilization of the tubercle bacillus from the infecting focus is one of the puzzling questions. It has been suggested that tuberculin may produce this effect, as in Rutimeyer's case of phthisis, in which tuberculous meningitis appeared after tuberculin treatment, though Cornet denies this. Tuberculous meningitis occurred shortly after operation in 8 out of 114 cases, and the interval between the operation and the meningitis infection reminds one forcibly of the incubation period in experimental tuberculosis. The route by which the bacillus traveled is not worked out. It is either by the blood or lymphatic vessels, and the marked alteration in the blood vessels is a striking fact in connection with tuberculous meningitis. In one case he could see tubercle in the walls of the sylvian arteries. The examination of the spinal fluid is a matter of importance in diagnosis, and while he has never been able to find the tubercle bacilli in the deposit in tuberculous meningitis, inoculation tests gave satisfactory results in three out of four cases. The points of importance in the examination of the spinal fluid are the presence of tubercle bacilli and lymph in the deposit, and the results of inoculation test. Trevelyan regards cryoscopic and permeability tests as of small significance. He thinks his lack of success in finding the tubercle bacillus was accidental. In rare instances one has the good luck to see recovery from symptoms of grave tuberculous disease of the brain, but it is often incomplete, blindness remaining; and in considering recovery from tuberculous meningitis we must distinguish between the general form and the partial meningitis. Monnier and others recommend operation for the latter. Bacteriologic proof of the nature of meningitis has been provided in cases recorded by Freyhan, Henkel, Barth, Gross, Winter and Gohl, the tubercle bacillus being found in the spinal fluid in all these cases. The cases of Henkel and Barth were living and well in 1903. Notwithstanding these recoveries the prognosis, however, must be still considered as generally hopeless, and the prophylaxis is worthy of the closest attention. Trevelyan advises the isolation of consumptives in careless families, especially if children are exposed, and the notification of phthisis and disinfection.

5. **The Overlaying of Infants.**—This seems to be a comparatively common occurrence in England, and Westcott ascribes it largely to intoxication on the part of the parents and thinks that the laws should be more stringent. He says it is now impossible to secure conviction in England for the manslaughter of infants by overlaying.

13. **Tuberculous Disease of the Knee-Joint.**—Monsarrat insists on the great value of early surgical interference. He gives the symptoms and describes his technic, and says that the indications for operative interference are as follows:

1. Cases of tuberculous foci in the neighborhood of the lower epiphysis of the femur should be operated on as soon as the diagnosis is established. 2. Cases of joint disease by extension from the femur should be operated on as soon as possible if this extension is recent, and if not recent, then when the disease does not definitely retrograde after about two months' fixation of the joint. 3. Cases of primary synovial disease should be operated on when after about three months of rest no distinct improvement has taken place.

14. **Diphtheria and Scarlet Fever.**—The gradations between diphtheria and scarlet fever are noted by Biss, who draws a schematic table of these complications. He claims that the shades of difference between scarlet fever, diphtheria and tonsillitis are so gentle and each grades into the other so much, not at one but at many points, that the diagnostician can seldom feel certain.

17. **Aspirin in Rheumatism.**—The advantages of aspirin in rheumatism are illustrated by cases reported by Mackey, who insists on the importance of using sufficient doses continued sufficiently long if relapses are to be avoided. His practice is to give it in 20-gr. doses or more, sometimes 30 grs., and he would alternate with the alkalies, though he has sometimes combined these with aspirin, notwithstanding the incompatibility that is claimed by some authorities.

19. **Curschmann's Spirals.**—Laslett suggests that Curschmann's spirals are in reality casts of the smaller bronchial branches similar in nature to the casts of true plastic bronchitis. In support of this he raises the following points:

1. Fibrinous casts frequently show spiral terminations; 2, these terminal spirals are practically identical in structure with the true Curschman spirals, also present in the sputum; 3, the spirals, at least in this case, owe their peculiar structure largely to the arrangement of the great number of cells present: and 4, some of the spirals terminate in two equal branches of smaller diameter

than the parent stem. This fact alone makes it difficult or impossible to believe that these structures are formed by a spiral movement.

22. **Uterine Fibroids.**—Doran says fibroids need no treatment in many cases and quotes Murdoch Cameron that not more than one-third of the cases seen require surgical interference, and many fibroids are never recognized. The course of the fibroid, however, is uncertain; we can tell what a cancerous cervix and an ovarian cyst will do, but a fibroid's course can never be foretold. We must be wary about the opinions of others, however authoritative; a hysterectomy for fibroid may be followed by complications worse than the original trouble, and the impossibility of calculating the future growth of the fibroid is too much in the background with advocates of hysterectomy. The operation is not a slight one; the chances of hernia, intestinal obstruction and infection are always to be considered. The most serious of all possibilities is psychic disturbance. When operation does not seem urgent treatment should be symptomatic; when bleeding is present ergot is not to be despised, except when cardiac disease exists. An abdominal belt to support the tumor anteriorly is always advisable. A light nutritious diet and certain mineral waters are of service. Electricity is not in favor with Doran; the effects he has seen have in some cases been bad. As regards the ovary in hysterectomy, he thinks it is impossible to absolutely extirpate all ovarian tissue, and in many cases an ovary left behind has produced no trouble. The simplest and best operation for supravaginal hysterectomy is the retroperitoneal one; the stump, being placed behind, is under the peritoneum outside its cavity. He has found that his patients do very well when amputation is made through the cervix, and the uterine flap need not be cut long. We should carefully study the history of all patients as regards the possibility of mental disease, and while evidence is in favor of the conservative treatment of the ovary there are some disadvantages. The ovary left may become the seat of a new growth and pieces of the fallopian tube may inflame or even suppurate. The inflamed ovary and tube should be always removed. When it affects both of the appendages the operator should never scruple to remove them. As regards suture, he favors the deep interrupted suture instead of suturing in layers. The statistics of hysterectomy must be judged on their own merits, and should not induce us to operate on every fibroid that comes under our care. He says that in cases where operative interference is most necessary the mortality is still considerable, but they do show that recovery is almost certain if a fibroid of moderate size is removed by an experienced operator. In most cases the patient is in certain respects a gainer by removal.

25. **Phthisis and Life Insurance.**—Lister finds from a study and an analysis of statistics that vulnerability to phthisis is practically the same at all stages of life. The actual danger to insurance companies from phthisis is made up of three factors: inherited vulnerability largely diminished after middle life, acquired vulnerability increasing with age and infection alike at all stages. The sum of these three factors causes the actual danger of phthisis to be about the same at all ages.

30 (II, No. 86.) *De la polyurie simple aux 2 premières périodes de la paralysie générale. E. Marandon de Montyel.
31 Traitement médicale de l'appendicite aigue. G. Lyon.
32 (No. 87.) *Treatment of Syphilis in the Newly Born by Injections of Soluble Mercurial Salts. Schwab and Levy-Bing.—Traitement de la syphilis chez les nouveau-nés par les injections mercurielles solubles.

30. **Polyuria in General Paralysis.**—The conclusions of examination of 54 patients with general paralysis indicate that simple polyuria is an early phenomenon in this affection, appearing before the onset of any other symptom. It was noted in about 16.66 per cent. of the subjects examined, but did not last longer than two months in any case, with one exception, in which it was manifest for five months.

32. **Mercurial Injections for the Newly Born.**—Schwab has treated 5 new-born infants exhibiting unmistakable syphilitic lesions by subcutaneous injections of an aqueous solution of the biniodid of mercury, averaging .5 mgm. of the mercurial salt a day. One infant weighed 3,160 gm. After two weeks of these injections it weighed 3,050, but the syphilitic lesions had commenced to subside, and in two more weeks had entirely disappeared, while the weight had increased to 3,410. A second infant presented generalized pemphigus and coryza, both parents syphilitics. He was treated by mercurial inunctions for six days after birth and then the subcutaneous injections were instituted, each .5 to 1 mgm., a total of 12 injections. The weight increased from 2,230 to 2,850 gm. in 24 days, and the child was in excellent condition, its skin all cleared up. It succumbed a few weeks later to an intercurrent pneumonia, and no syphilitic lesions could be discovered on the skin or internal organs at the necropsy. A third infant was apparently healthy at birth—the mother a confirmed syphilitic—and seemed to thrive well for a few days, when the weight began to markedly decrease. On the assumption that this was due to the syphilitic taint the injections were commenced, and after 9 daily doses of 1 mgm. the condition was again satisfactory and the weight continued its regular increase afterward. Another infant with marked pemphigus was injected with 1 mgm. the very evening of its birth, the injections continued for two weeks, the dose sometimes as large as 1.5 mgm. The results here were equally gratifying. The fifth child was three months old when the injections were commenced. He had been born at the seventh month, both parents victims of comparatively recent syphilis. He seemed to thrive at first, but then gradually declined. Under the injections of 2 mgm. of the biniodid he recuperated, and after 6 injections the improvement was remarkable. The number of injections in these 5 cases ranged from 6 to 16. The bowels were normal, and all the infants increased in weight. The injections were perfectly tolerated in every case. The formula used was .05 gm. mercury biniodid and the same amount of sodium iodid, in 10 c.c. of distilled water.

Semaine Médicale, Paris.

33 (XXIII, No. 43.) *At What Age Do Tabetics Die? P. Marie and P. Mocquot.—A quel age meurent les tabétiques?
34 Report of French Congress of Surgery. (Concluded from No. 42.)
35 (No. 44.) *Medical Instruction in the United States. F. Munch.—Les études médicales aux Etats-Unis.
36 L'accroissement de la population de France comparé à celui des principaux pays d' Europe.

33. **Age at Time of Death in Tabes.**—Marie and Mocquot do not believe that syphilis shortens life in the majority of cases. Their experience with 66 tabetic subjects dying at the Bicêtre during the last few years, demonstrates that tabes likewise does not have much influence on the length of life. They mention that these subjects exhibited no other indications of syphilis, aside from their tabes, sufficiently serious to shorten life. Among 20 blind tabetics 50 per cent. were more than 60 years old at the time of death and 17 were over 50. In the total 66 more than 83 per cent. were over 50 and 51.5 per cent. more than 60. The 7 who died under the age of 45 succumbed to an intercurrent disease or committed suicide. Of the 58 tabetics at present in the hospital more than 43 per cent. are over 55 and nearly 69 per cent. are over 50. The rapidly fatal form of tabes sometimes observed is probably in most cases merely general paralysis with the tabetic symptoms predominant, that is, an acute or subacute general taboparalysis. When tabes reaches a certain stage it seems to become stationary, and long survival in this phase is possible and probable.

35. **Medical Instruction in the United States.**—Munch compares the requirements for admission to our medical colleges and other details with those prevailing in Europe. He states that only one of the 154 medical schools in this country regards the clinic as of sufficient importance to impose a hospital course on the students. This same school is the only one in which the requirements for admission are approximately equivalent to the requirements of a French medical school. It is also the only one in which the number of students is kept down, and it thus answers the purpose of a hotbed for producing professors and scientists. As a rule, he remarks, the practical side of medical instruction here is always sacrificed to the theoretic side. The clinical side is absolutely neglected. He comments on the shortness of the terms, especially when the lack of previous training of the students is considered. Aside from a few schools which are an honor to the country and which may well bear comparison with similar establishments in the old world, there are too many others whose disappearance would add to the success and credit of the country.

46 Entstehung der Hygrome. Langemak (Rostock).

39. **X-Ray Treatment of Sarcoma in Skull.**—The tumor was the second recurrence of a large round-celled sarcoma of the occiput with metastatic nodules in the frontal bone. Under the *x*-rays all the lesions vanished in the course of two months and the patient has been cured to date, four months since. A hard tube was used, at a distance of 15 to 20 cm., the daily sittings ten minutes each. The hair fell out, but has grown again; no other by-effects were observed.

40. **Rupture of Biliary Passages.**—A boy between 2 and 3 years old was run over by a wagon and was brought to the clinic three weeks later with slight icterus, ascites and clay stools. Puncture allowed the escape of nearly three quarts of a bile-stained fluid. An operation was undertaken seven weeks later and revealed fibrinous peritonitis with numerous adhesions. The hole in the biliary passages was not discovered, but complete cure followed the establishment of an anastomosis between the gall bladder and duodenum. Lewerentz reviews 60 similar cases that have been published. When the bile escapes into the abdominal cavity in large quantities a fatal termination is inevitable partly on account of absorption of the constituents of the bile and partly from the loss of this important factor in digestion.

41. **Acute Invagination.**—Barker has operated on 25 cases and has had 7 deaths. He never attempts to correct the invagination by high injections, except in the very earliest stages. The invagination should never be reduced by traction on the invaginatum but only by pressure on the peripheral end, squeezing the intussusceptum out of its sheath.

42. **Antiseptic Dressings.**—Noetzel's experimental research indicates that the secretions of a wound are drawn up into a moist dressing better than into a dry one. Virulent anthrax bacilli placed on an artificial wound in rabbits were absorbed into these dressings and infection of the animals was prevented. Both the moist and the dry proved equally effective in this respect, but the germs were drawn up into the outer layers of the moist gauze while they were found only in the layers closest to the wound in the dry dressings.

45. **Indications for Cardiolysis.**—By this term Brauer means the freeing of the heart from rigid fixation by chronic mediastino-pericarditis. As persons in this condition are unable to bear a major operation with the necessary narcosis, he recommends removal of the bony wall over the heart, which frees the heart to a great measure. He has thus operated on two patients and the working capacity has been restored in each; the cyanosis, congestion of the liver and ascites have vanished, and the myocarditis has been improved, although not cured. The symptoms of chronic mediastino-pericarditis include congestions, progressive cardiac insufficiency, diastolic heart beat, etc., and the pulse curve is also characteristic, as he explains in detail. The most important of these symptoms, the insufficiency of the heart, is relieved by removal of the rigid chest wall to which the heart becomes more or less fastened by adhesions.

47. **Indications for Premature Delivery in Heart Disease and Hyperemesis.**—Tuszkai points out that many cases of the latter are due to hysteria, auto-intoxication, etc., and that interruption of the pregnancy would not remove the cause. He attributes essential hyperemesis to irritation of the perimetrium, and believes in terminating the pregnancy as a last resort after failure of all other measures, including opium, and progressing inanition is becoming a serious menace. Premature delivery is seldom necessary in case of a cardiac defect. The only indications for it are the early appearance of signs of disturbance of the compensation, especially irregularities in the pulse indicating increasing dilatation of the heart. He calls special attention from this standpoint to the lack of the normal difference between the pulse of the reclining and erect subject, and the exaggeration of this difference later as the pregnancy advances. He regards this as a valuable sign of incipient failure of compensation.

48. **Cytodiagnosis.**—Schwarz and Bronstein report trials of this diagnostic measure which have failed to demonstrate that it has much, if any, utility.

49. **Importance of Oatmeal in Diabetes.**—The oatmeal course of treatment outlined by von Noorden consists in daily ingestion of 250 gm. of oatmeal or rolled oats thoroughly cooked with 300 gm. of butter and 100 gm. albumin. The

last-mentioned may be in the form of a vegetable albumin cooked with the oatmeal, or the white of an egg may be added after it is partially cooled. The porridge thus made is taken at two-hour intervals. His experience with a hundred cases shows it is possible on this diet to partially or completely banish the sugar from the urine and likewise the acetone bodies. It is contraindicated in mild cases without diaceturia, as the oatmeal is not tolerated by such subjects. No theory has yet been advanced to explain the facts observed in regard to the benefits from a change to oatmeal in severe cases except that it may possibly be due to a difference in the kind of starch. They confirm the necessity for individualizing treatment in diabetes. He has been testing this oatmeal diet for more than a year and gives in tabulated form 5 typical cases illustrating the effects as observed in various groups. He allows at the same time a little brandy or wine and a little strong black coffee. The oatmeal he uses is Knorr's *Hafermehl* or the Hohenlohe *Haferflocken*. The first case is that of a young man, 18 years old, who had presented symptoms of diabetes for six months. Notwithstanding strict adherence to the usual antidiabetic diet he averaged from 20 to 96 gm. of sugar a day, with 1.5 to 2 gm. acetone and 1.5 to 3 gm. ammonia. These proportions were progressively increasing and a change was made to the oatmeal diet. The acetone vanished by the third day and the sugar dropped from 50.9 gm. to zero in a week. Von Noorden has had 10 cases of this type. After two months of the oatmeal diet, varied occasionally with a little bacon, eggs or vegetables, he was dismissed, with orders to keep to a modified form of this diet: For breakfast, tea or coffee, with cream, and 2 eggs; for early lunch, 20 gm. of oatmeal cooked with 30 gm. butter, 50 gm. bacon and 2 yolks of eggs. For the midday meal, 120 gm. meat, abundance of green vegetables and a salad, 50 gm. potato, 25 gm. cheese and coffee with cream. For the fourth meal, tea with cream and 2 yolks, and for supper, 80 gm. meat, green vegetables in abundance with an oil salad, 50 gm. potato, 25 gm. cheese, and butter. Every day a Rademann *Luftbrod* (aërated bread made from gluten free from carbohydrates) and 100 gm. of a "desugared fruit preserve," *entzuckertes Obst*. Every fifth day a "vegetable day" is interposed. Three-fourths of a bottle of light wine is also allowed daily. On this diet the patient's urine has been completely free from sugar since last April. Case 2 was a patient with diabetes for ten years, and the oatmeal diet restored the balance of toleration which had been lost for a time, as shown by increasing weakness, etc. It reduced the sugar from 131.8 to about 30 gm. and also reduced the acetone. In three weeks the patient was restored to his regular balance of toleration and has been in comparatively good health since. In a third group, the interposition of the oatmeal diet evidently warded off impending coma. In the typical case described the sugar was completely banished after it had reached 110.7 gm. a day, and the patient gained in weight on the oatmeal. In the fourth group of cases the oatmeal aggravated the condition. In the typical case tabulated the patient was a man of 27 who had shown signs of diabetes for more than two years, the first symptoms noted after a fall on the back of the head. When he entered the clinic the sugar ranged from 75 to 123 gm. and the oatmeal diet proved less effectual in reducing the sugar than the ordinary diabetic diet, and the acetone increased. In the fifth group the typical case was that of a man of 33 with 57.7 to 98.8 gm. sugar. On a strict diabetic diet the sugar had been banished from the urine, but it returned in nearly as large proportions as at first when an oatmeal diet was instituted. The effect on the sugar in the urine is never so pronounced with Winternitz's milk and Mosse's potato diet as is obtained in appropriate cases with the oatmeal.

53. **Fever and Glycosuria.**—Richter induced glycosuria in animals with adrenalin and then raised the temperature by irritation of the corpus striatum, without modifying the glycosuria. The elimination of sugar induced by the adrenalin was not affected by the subsequent high temperature. On the other hand, there was no glycosuria when fever was induced by injection of streptococci with subsequent administration of adrenalin. He assumes that the bacteria use up the sugar in the blood. This would explain the increased tolerance to sugar in alimentary glycosuria and diabetes during febrile affections.

54. **Pathogenesis of Pulmonary Tuberculosis.**—Weleminsky infected a number of animals with tuberculosis by way of the alimentary canal. He found that a number subsequently developed pulmonary tuberculosis, showing that the infection must have reached the lungs by way of the submaxillary and bronchial glands into the blood and thence to the lungs. The germs settle in the lungs, as they meet less resistance here.

55. **Nasal Relation of Dysmenorrhea.**—Opitz accepts the possibility that the uterus may be influenced by way of the nose. This assumption is sustained by the close connection between the sense of smell in animals and the sexual activity, which in the female probably leads to contractions of the uterus from stimulation of the olfactory nerves. Something similar possibly occurs likewise in human females. As dysmenorrhea in many cases is due to abnormally vigorous or abnormally perceived contractions of the uterus, it may be considered in many cases a reflex neurosis, and as such may be amenable to treatment through the genital points in the nose. His clinical experience sustains this assumption. It certainly affords the practitioner another weapon for combating dysmenorrhea.

57. **Hot-Air Treatment of Ear and Nose Affections.**—Warnecke uses an apparatus of his own devising, which is described and illustrated in this communication. He has found the hot air extremely useful after operations, also for empyema of the antrum of Highmore and in chronic otitis media.

58. **Hysteric Autosuggestion in Children.**—Ewald describes 3 cases in boys from 7 to 9 years old in which the hysteria was not pronounced. Removal to another environment or a sham operation cured the condition. The autosuggestion involved the abdominal organs in each instance and simulated a foreign body and appendicitis. The third child vomited and regurgitated constantly.

59. **Comparative Sensitiveness of the Iodin Tests.**—Rogovin has been testing the various reactions that have been published. He found that it was possible to detect the iodin in the urine even after ingestion of as small an amount as .005 gm. of potassium iodid. The Harnack reactions proved much more sensitive than any others. The Sandland test is also reliable, but Jolles' and the others failed when the proportions were small. He gives the technic of the various tests in detail.

60. **Action of Bile on the Heart.**—Brandenburg found that even a very small amount of bile injected into the circulation of frogs and dogs had an irritating effect on the sensory innervation of the heart and induced reflex irritation of the vagus with transient enfeeblement of the contractions of the auricles and slowing of the heart beat. This occurred in the experiments on animals much sooner than in icterus in man. Reflex irritation of the vagus seems to be an important factor in the development of the disturbances in the circulation observed in icterus. Its effect is supplemented by injury of the cells of the myocardium at the mouths of the large heart veins.

61. **Vegetable Foods and Drinks in Respect to Gout and Nephritis.**—Hall calls attention to the large proportion of the purin nitrogen which is contained in oatmeal, beans, peas, asparagus and onions, also in beer and ale. These articles of diet and these beverages should, therefore, be prohibited or restricted in gout and nephritis.

62. **Sanoform as Substitute for Iodoform.**—Bamberg has used sanoform in 225 cases, mostly gynecologic, and has been much pleased with this odorless combination of iodin and salicylic acid. It does not seem to have any direct bactericidal power and its therapeutic action is due to the liberation of the iodin and salicylic acid. He is now using it exclusively in the place of iodoform.

64. **Leukanemia.**—Luce applies this name to the rare blood affections characterized by the combination of the blood findings of pernicious anemia with those of lymphatic leukemia. In a case recently observed a woman, 40 years old, presented an acute angina followed by the gradual development of a hemorrhagic diathesis with hemorrhages into the retina, morbid heart sounds, and enlargement of the glands in the neck, the liver and spleen, proceeding to a fatal termination in six months. He regards the case as merely one form of the morphologic manifestations with which the blood-forming apparatus responds to a series of injurious influences. It is introduced by some lymphadenoid or myeloid metaplasia of the bone marrow of unknown etiology. The pernicious anemia is, therefore, myelogenic and not hematogenic in this leukanemia.

65. **Westphal's Sign in Croupous Pneumonia in Children.**—Roeder denies that the knee-jerk has any significance for either diagnosis or prognosis in croupous pneumonia.

66. **The Muscle Troubles in Thomsen's Disease.**—Jensen states that comparison of the muscle curve obtained with the Mosso ergograph in health and in myotonia congenita shows that the primary contraction occurs much more slowly in the latter. Instead of the normal 2 seconds, 8 are required for the contraction of the myoclonic muscle. He is inclined to attribute this and the other peculiarities observed to some anomaly in the muscle itself, possibly in the terminal ramifications of the motor nerves in the muscle. It is probably some nutritional disturbance in the assimilation of the contractile muscle fibers or sarcoplasma and defective disassimilation. He found in his experience with a case of this disease carefully studied that thyroid tablets and injection of orchitic extract induced a temporary improvement. He also imagined that benefit was derived from inhalation of oxygen, which he gave on account of its efficacy in promoting metabolic processes in general. The results observed justify further trials of oxygen.

68. **Antiperistalsis in Stomach.**—In 2 cases of gastric tumors Rautenberg noticed marked antiperistaltic movements in the stomach.

69. **Eosinophiles in Various Diseases.**—Reckzeh's investigations of 70 subjects showed that in scarlet fever the eosinophiles range from 0 to 23 per cent. of the white corpuscles; in measles from 0 to 5 per cent. None were to be found in erysipelas. In diphtheria the number corresponded to the normal figure. In leukemia there was a moderate increase; in pernicious anemia they were absent. In mercurial dermatitis the eosinophilia commenced at the point of irritation, but became general later.

70. **Blood Pressure During Exercise.**—Moritz remarks that a very slight increase in blood pressure during hard exercise indicates some severe functional heart trouble. In case of slight valvular defect the blood pressure may behave normally during exercise, but with serious valvular defect it varies as in case of myodegeneration, that is, the blood pressure is increased during the exercise, but never reaches the normal height, and is liable to drop even during the muscular exertion; afterward it returns to normal much more slowly than in health. The amount of disturbance in the circulation and the condition of the heart muscle are of greater importance from this point of view than the kind of the valvular affection. In health the Riva-Rocci apparatus shows that the blood pressure does not rise during mild exercise, but during vigorous muscular exertion it rises with the exercise, remains at a regular height and subsides to normal at the close. The more will power and exertion required for the exercise and to maintain it in spite of augmenting fatigue, the higher the blood pressure. In case of heart disease the blood pressure may fall below normal after the conclusion of the exercise, showing the fatigue of the heart. These statements are the results of tests according to Dehio's method on 6 healthy subjects, and on 23 with heart disease.

71. **Treatment on New Basis of Circulatory Disturbances.**—The favorable action observed under certain circumstances from therapeutic gymnastics in cardiac and valvular affections, is explained by Hasebroek on the basis of a new theory which he tentatively proclaims. The theory of the circulation as the result of the difference of pressure between the arteries and veins induced by the constantly recurring action of the heart, does not explain all the phenomena observed. He thinks that we can assume a further propulsive energy at the periphery independent of that in the heart. The periphery represents another, second, independent pumping apparatus, coupled with that of the heart. The periphery has not only its elastic contraction and expansion, but also its active diastole and systole in the arteries. This diastolic-systolic activity is manifested in the capillaries as a sucking in, an inspiration, while in the arteries it is more of a propulsive energy. Both these forces combine to compel an independent and vigorous flowing through of the blood stream into the veins. The latter are passive, serving as a passive reservoir for the blood stream, and thus the venous system is able to adapt itself at all times to the varying activity of the organs at either end. This peripheral diastolic-systolic, independent, propulsive apparatus may become impaired and entail various disturbances in the circulation. The heart by redoubling its efforts may compensate for a time the lessened activity of the peripheral apparatus, or the latter may compensate for deficient heart action. The beneficial effects of therapeutic gymnastics are restricted to those cases of circulatory disturbances in which the heart is still sound and the trouble is due only to some disorder in the peripheral pumping apparatus. If the heart muscle is already affected, benefit can be attained only when it is possible to stimulate the vitality of the peripheral tissue and by functional exercise of its vessels to exert a favorable influence on this independent peripheral circulation. When both heart and periphery are affected, no benefit can be derived from such exercises. The assumption that exercise strengthens the heart muscle is a mistaken one. The vitality of the heart is increased by sparing it unnecessary exertion, and by inducing compensation on the part of the independent propulsive force at the periphery. Therapeutic exercises are an important prophylactic measure in the early stages of chronic disturbances in the circulation and in well-compensated valvular defects. They prevent or retard the progress or inception of the vicious circle in the circulation, that is, the chain of sluggish current, increased resistance and diminished volume of blood sent forth at each beat, entailing a still more sluggish current, etc.

81 Life Insurance Formulas. O. Schellong (Königsberg).—Die Formuläre der Lebensversicherungsgesellschaften.

72. **Fatty Degeneration.**—Ribbert argues to prove that fatty degeneration is essentially in all cases an infiltration of fat into previously injured cells. Fat enters into normal cells

and accumulates as deposits of fat, forming the adipose tissue. When it enters into pathologic cells we have fatty degeneration. The two processes may thus be regarded as a physiologic and a pathologic fatty infiltration.

74. **Fragmentation of Feces.**—Grützner has found that feces may be readily broken up if alcohol is poured over them. He uses an ordinary egg beater, the kind made with the wire wound in a spiral cone, the handle fastened to the tip of the cone.

75. **Intracapsular Resection of the Prostate.**—Riedel relates the details of 5 cases treated by excochleatio prostatæ. One patient had been using the catheter for two years. He was able to urinate spontaneously the evening after the intervention. As his bladder was sound and the urine had not putrefied, the benefit derived has been permanent. In another case the prostate was located at an unusual height and the bladder presented a diverticulum so large that it might be considered a supernumerary bladder. This anomaly was not discovered at the first operation, when the prostate was shelled out, and the patient did not survive the second operation, the obliteration of the diverticulum. He was a man of 61, a consumptive with contracted kidney, and his urinary disturbances were of three years' standing. The removal of the prostate restored spontaneous urination for several months, until the bladder became insufficient. The 2 other cases were successful, although the urethra was injured in each. Riedel's experience demonstrates that the operation should be undertaken while the bladder is still sound. When it is insufficient, the residual urine will collect and putrefy, and the patient's condition be actually aggravated, as before the intervention the residual urine had been evacuated with the catheter, which after the operation is discarded. He would be inclined to recommend the operation to younger men, even if he found it necessary to repeat it later on account of renewed growth of the prostate. He works through an incision curving from one tuber ischii to the other, a short distance in front of the anus, with a longitudinal incision to the scrotum.

77. **Rapid Hardening and Embedding.**—In brief, the modification of the Lubarsch method described consists in 5 minutes in 10 per cent. formalin; 5 minutes in 95 per cent. alcohol; 10 minutes in absolute alcohol changed once; 15 to 20 minutes in anilin oil until entirely transparent. During these maneuvers the specimen is kept in the incubator at 50 to 52 C. The temperature of the incubator is then increased to 58 or 60 C., and the specimen is placed in xylol for about 15 minutes, changing the fluid two or three times, and lastly in paraffin for 10 to 30 minutes. The entire procedure is complete in 75 to 90 minutes. It is applicable only to sections not more than 3 mm. thick. Specimens thus prepared eighteen months ago are still in perfect preservation. Gutmann and Stein both commend this method as preferable to all others for rapid, exact diagnosis from curettings, etc.

79. **Mechanical Treatment of Infants' Obstipation.**—Clamann introduces an oiled, medium-sized, Nélaton catheter into the rectum as the infant lies on his back. He works it in for 15 cm. or more and twists it gently to induce reflex expulsive action on the part of the intestines. This "oil catheter" has never failed him in several years' experience with it.

92 Zur Behandlung des Abortus. O. Knelse (Halle).

83. **Sterility and X-Rays.**—Albers-Schönberg reports experiments on animals showing that *x*-raying produces in them a marked inability to reproduce, whether transient or permanent is yet to be determined, and this without any decided interference with the general state of health. The consequences of the rays, sterility, is by the killing of the spermatozoa, which soon reaches the point of complete azoöspermia. He experimented effectually on 5 rabbits and 6 guinea-pigs with from 377 to 518 minutes of *x*-ray application in different cases. Exposure of 195 minutes did not produce a complete effect.

85. **Aneurism of the Hepatic Artery.**—In the case reported by Kehr there was an aneurism of the right branch of the hepatic artery which necrosed and connected with the cystic duct. The artery was tied with double ligatures and severed between them immediately below the bifurcation, and the aneurism, the size of a goose egg, was exposed and cleared out. Tamponade was applied without drainage. The stomach was found to be sound and no other lesions were discovered. The patient made a good recovery. A careful watch was kept during the first forty-eight hours for signs of liver necrosis but it did not appear. He remarks in regard to such cases that symptoms of gastric or intestinal bleeding with colic and icterus together, should lead to a suspicion of the possibility of aneurism of the hepatic artery.

86. **Tuberculin Diagnosis.**—Grünenwald believes that the diagnostic use of tuberculin is without danger, and gives the results of his own experiments. He used the old tuberculin of Koch, and employed about 1 mg. in the beginning, later increasing to larger doses in some cases where reaction was not prompt. The injections were made between the shoulder blades. In the 117 cases, 89, that is, 76 per cent. gave a positive reaction; 28, or 23.9 per cent., a dubious or negative reaction. In 103 cases presenting pronounced or suspicious symptoms of pulmonary tuberculosis, 88, that is, 85.4 per cent., gave a positive reaction; 7, or 6.8 per cent. dubious, and 8, or 7.8 per cent. negative. Out of 8 patients with bronchitis associated with chronic pneumonia and bronchiectasis, 2 reacted positively and 6 negatively. In 6 pleuritic cases, 2 gave a positive reaction and 4 a negative. The occurrence of these negative reactions in patients who exhibit decidedly marked symptoms of tuberculosis is remarked on, and it is admitted that there is much yet to be studied in regard to the working of tuberculin in this regard, though its value is not questioned.

89. **Streptococcus Serum Treatment of Mixed Tuberculosis Infection.**—Menzer has used antistreptococcus serum in 11 cases of Turban's first stage of tuberculosis. Of these, 8 recovered with an average increase of weight of 12 pounds in 3.2 months; 3 were perceptibly improved with an average increase in weight of 5 pounds in 1.4 months. In 3 cases in the second stage, 1 recovered with 10 pounds increase of weight in 3 months. One was perceptibly improved in the same time with a still greater increase of weight and one also improved in less than 2 months with a slight increase. Five cases in the third stage were perceptibly improved, and 3 were not. Recovery, as here understood, is a disappearance of all catarrhal phenomena, with still slight apical dullness and alteration of the respiratory sounds. The maximum of serum injected was about 5 c.c. in the first stage; the injections were made ordinarily in the upper thigh. He began with .5 c.c. and gradually increased the dose up to the above limit.

98 Zur therapeutischen Wirkung der Bier-Hefe (yeast). Goliner.

93. **Treatment of Retroflexion.**—Winternitz thinks that movable retroflexion without complications in nulliparæ does not cause any special nervous disturbances, and consequently does not call for treatment. If nervous disturbances are noted in child-bearing women, such as are especially liable after forceps deliveries, and also in case of complicating displacements of the vagina, a round ring pessary remedies the conditions better than any other. The symptoms will be improved to such an extent as to demonstrate in the latter case that the trouble was due to the sliding down of the vaginal walls rather than to the retroflexion.

94. **Albumin Diet.**—Bermbach is an earnest advocate of an abundant supply of albumin in all cases of myodegeneration of the heart, severe anemia, hysteria and stomach affections. He discusses various modes of providing the albumin, and expresses his preference for tropon or eucasin, two tablespoonfuls a day.

95. **Lecithin in Brain Fag.**—Fürst has witnessed most remarkable success from the administration of two lecithin pills three times a day in cases in which the brain was fatigued or exhausted from any cause. He thinks that we have in lecithin a most valuable agent for toning up the brain when suffering from overuse. It supplies the phosphorus in an active, organic form, and the entire metabolism soon shows the benefit derived. In six to eight weeks the brain becomes much clearer and more active. The favorable results of ingestion of eggs, milk, brain substance, spermin and cerebrin, are undoubtedly due to the large proportion of lecithin they contain.

109 *Zur klinischen Behandlung der entzündlichen Adnexerkrankungen (adnexitis). O. Nebesky.
110 Zur histologischen Diagnose des Abortes. E. Opitz.

99. **Tumors of Placenta.**—Dienst does not consider 3 of the 46 cases of tumors of the placenta on record as quite above criticism. He describes 2 personally observed, which brings the number of reliable cases to 45. All on record to date may be called choriomata, but there is both an angiomatous and fibrous variety. He attributes the origin to some congestion in the maternal organism.

100. **Inoculation Metastases.**—Olshausen has encountered 6 cases of metastases in the abdominal wall consecutive to ablation of a malignant tumor. They are always located on one side of the cicatrix. One proved to be an inoperable carcinoma, occurring two years after removal of a carcinomatout ovarian tumor; another developed likewise two years after bilateral ovariotomy, and another five years, and a fourth seven and one-half years afterward. In the other cases the carcinoma in the abdominal wall developed seventeen and twenty-one years after ovariotomy or extirpation of an ovarian tumor. He further reports 3 cases of tardy recurrence. In one a sarcoma recurred in the ovary four and a half years after ovariotomy. In another a carcinoma developed in the other ovary and uterus seven years after ovariotomy, and in the third, there was metastasis of a carcinoma twelve years after ablation of the primary growth. All these tumors developed in the vicinity of the cicatrix, and hence are undoubtedly due to inoculation during the operation, although the long latency of the particles of the carcinoma is very remarkable.

101. **Study of Glands in Case of Uterine Carcinoma.**—Oehlecker found microscopic metastases in some of the pelvic, lumbar or retroperitoneal glands in 2 out of 7 cases thus examined. No macroscopic evidences of cancerous degeneration were perceptible. He advocates removal of all the regional glands, irrespective of their size or consistency.

103. **Opposition to Drainage.**—Olshausen does not believe in drainage after gynecologic operations except those for paratyphlitic abscesses or suppuration in the broad ligaments or on the floor of the cul-de-sac. He drained in only 9 of his last 1,555 laparotomies. This series includes 113 cases of very extensive interventions in which subsequent sepsis would have been of the most serious import, and yet all progressed favorably without drainage. He regards it as more of a danger than a benefit, except for the conditions enumerated above.

109. **Clinical Treatment of Adnexitis.**—Amann is restricting more and more operative treatment of inflammatory processes in the adnexa in favor of expectant, conservative measures. He finds that persevering conservative treatment will in time restore the working capacity in nearly every case, mild or severe. The objective findings and complications are very rarely indications for operative treatment, but subjective troubles occasionally justify it after the failure of months of conservative treatment. Nebesky reviews 360 cases. The principles of conservative treatment are repose, good food and avoidance of possible sources of injury, supplemented by hydrotherapy and balneotherapy. Three to six months are generally necessary for a complete cure. A suspicion of the tubereulous nature of the process, however, always imposes speedy operation.

116 *Sull ' infezione mista : tifosa e diplococcica. C. Quadrone and E. Cler (Turin). (Commenced in No. 41.)

113. **Rupture of Urethra.**—In the 2 cases described, Sorrentino incised the perineum and inserted an elastic catheter backward into the bladder, then bending it he was able to introduce the other end of the catheter into the peripheral stump of the ruptured urethra, the tip emerging from the external meatus. He then sutured the urethra and the wound in tiers, using catgut. The wounds healed by primary intention, and there has been no trace of disturbance since. He was careful not to include the mucosa of the urethra in the suture, and drained with a narrow strip of gauze for forty-eight hours, leaving the elastic catheter in the urethra for eight to ten days, changing it only once during this time.

115. **Circular Incision of Leg for Varicose Ulcers.**—Dall' Acqua aims to show by clinical experience, experimental research and theoretical reasoning that the results of this method of treating varices are far from good. The only benefits he derived were the temporary cessation of the pain and the rapid healing of the wound. The advantages claimed for it by its author, Moreschi, are not realized in practice, and recurrence is frequent afterward.

116. **Mixed Typhoid and Diplococcus Infection.**—In the 2 cases reported the Widal test was extremely marked.

Address.

THE PROGRESS OF AMERICAN MEDICINE AND ITS RELATION TO PUBLIC AFFAIRS.*

W. W. GRANT, M.D.

DENVER.

A brief allusion to history and to current medical literature is not without interest and instruction in the progress of medicine and surgery and their relation to public opinion and to the public service. In the determination of some such questions and matters we are forced to deal largely with the body politic. What the profession has done everywhere for the public good, and what it has accomplished even in our own country, may be in itself a sufficient answer to the political motives and aspersions, and the debauchery of science, in the name of humanity and personal rights, with which it has to contend and over which it ever has and will continue to triumph. In the cause of scientific truth and progress it is our duty to protect the people against their own ignorance and folly in matters of public health, as it is the duty of the state to make and enforce laws by appropriate legislation for the public weal. From the initiative of Mondini in human dissection in the fourteenth century to the more perfect establishment of it by the immortal Vesalius in the sixteenth, dates the beginning of the scientific study of medicine. This was the necessary fundamental step from that long period of priestcraft, sorcery and astrology, with here and there a spark of truth and light; the glowworm of the brighter day from the darker past. From that day to this, resplendent with new truths and benefits to humanity, the medical profession has contended with selfishness, ignorance and superstition in the discovery of new truths and in the enactment of every measure and law for the benefit of mankind, including every effort and measure for its own improvement, that it might the better meet the demands of humanity and a progressive civilization.

Jenner's discovery, and its application to the prevention of smallpox, has rendered the civilized world immune to its greatest plague, yet there are still anti-vaccination societies. Vivisection, generally painless, without which many of the most important truths of physiology would not be known or demonstrated, is still under the ban of much ignorance and prejudice. If these necessary acts were guided by liberal and beneficent laws, public illusions would more rapidly disappear, and "body-snatching" would only be a tradition.

One hundred years ago a distinguished English writer asked, "What does the world yet owe to an American physician or surgeon?" This is a partial answer: The first volume of medical transactions published in this country was in 1788. The first medical journal published was in 1820, and the use of American text-books was of a more recent date. Twitchell, New Hampshire, in 1805, was the first to ligate the common carotid and under most adverse conditions; Gibson, Maryland, the first to tie the common iliac; Valentine Mott the first to do it successfully (1827); Mott the first to tie the innominate, in 1818; amputated hip joint in 1824, and the first to amputate the entire clavicle, which was done in 1828, without anesthesia, of course, in four hours' time. Physick invented the tonsillotome, and was the first to apply rest in hip disease and in opposition to prevalent teaching. He was the inventor of absorbable ligatures and was a great lithotomist. In 1827, it is reported that he operated for stone on the venerable Chief Justice Marshall, who returned to his Virginia home on horseback in five weeks from date of operation.

Post and Rogers, New York, first ligated the subclavian in 1846. Deiderick, Tennessee, was the first to amputate the inferior maxilla, in 1810, and Jameson, Baltimore, the first to excise the superior maxilla, in 1820. Warren, Boston, was the first to extirpate the parotid, in 1804; Swift, Pennsylvania, the first to use extension in fractures; Harris, 1830, the first to excise the tongue; Knight, Connecticut, 1848, the first to use digital compression in the cure of aneurism; Walcott, Milwaukee, the first to perform nephrectomy, and Boggs, Indiana, cholecystotomy, while the original work of Christian Fenger will not be forgotten. The world pays its tribute to McDowell, the first ovariotomist. 1809. Joseph Pancoast was the first to operate for exstrophy of the bladder; Frank Hamilton the first to suggest skin-grafting, 1847; Bowditch, the author of thoracentesis, in 1850, and Warren of paracentesis. Professor Crosby of Dartmouth Medical College, 1838, was the first to amputate both clavicle and scapula, the interscapulothoracic amputation. Carnochan, 1858, was the first to resect the superior maxillary beyond Meckel's ganglion for neuralgia, and the recent Hartley-Krause operation on the gasserian ganglion is well known. Detmold was the first to trephine for brain abscess, in 1849. The great debt the modern world owes to the original work of Sims in gynecology needs only to be mentioned.

In intestinal surgery, the best methods of anastomosis, the Murphy button and the Connell suture being

* President's address at the twenty-third annual session of the Colorado State Medical Society, Denver, October, 1903. The introductory parts of the address relating to matters of local interest and the paragraphs concerning vital statistics, the examination of sight and hearing of school children, the appointment of a physician on the Interoceanic Canal Commission, the Tuberculosis Congress at Washington in 1905, and the organization of the National Auxiliary Committee on Medical Legislation are omitted in publication.

representatives of the class, and the more recent progressive work is chiefly by American surgeons; while we are the pioneers in appendiceal knowledge and operative work. Fitz wrote the first valuable paper on perforation of the appendix late in 1886, while the preliminary work of Barker and Sands fills an important place, and to an American surgeon belongs the honor of being the first to open the abdomen and remove the appendix, Jan. 4, 1885.

Morton of Boston was the first to publicly demonstrate ether anesthesia in 1846, but it is conceded that Crawford Long of Georgia first discovered and used it in a surgical operation in 1842.[1]

Notwithstanding the large number of public benefactors in the medical ranks, it has been a subject of comment and criticism that no portrait of a physician graces the "Hall of Fame," but we allude with professional pride and appreciation to the fact that of the two statues accorded to each state in Statuary Hall in the national capitol, Georgia recently selected, as one of the two, Crawford Long, the discoverer of anesthesia. This is the first and only state so far to justly pay a fitting tribute to a medical man for his contribution to the cause of humanity; for while vaccination has saved more lives, anesthesia has relieved more pain and suffering than any other discovery.

In American medicine we are not unmindful of the valuable original work of Gerhard, Dickinson, Parrish, Mitchell, Meigs and others, while to Oliver Wendell Holmes belongs the credit of establishing the infectious nature of puerperal fever. Dr. Nott and Dr. Charles Finlay were the first to claim that the mosquito was the bearer of the yellow-fever contagium, but the late lamented surgeon, Walter Reed, aided by Major Gorgas and Lieutenant Carroll of the medical department of the Army, in 1900 established the fact that a certain breed of mosquitoes was the inoculating agent. As a result, two striking facts are manifest in the short space of one year—one in Cuba, the gem of the West Indies, the other in Sierro Leone of West Africa, under English domination, and known, until these discoveries, as "the white man's grave." Now, with the simple application of drainage and petroleum to the stagnant, filth-breeding waters, the home of the plasmodia and mosquito, the two chief cities, Havana and Freetown, have been converted from pest-houses to pleasure resorts. One a menace to English civilization, the other to the health and commercial interests of our own country; now, under American medical investigation and the work of the Marine-Hospital Service, both safely opened to the industrial genius and commerce of the civilized world.

This is a brief and very imperfect summary of important original contributions of America to the progress of medicine and surgery, while the work of to-day excites the interest of the professional world and the pride of our own countrymen. Though the history of the "young republic" is brief, it is important and significant, and I fancy that no one would expose his ignorance by now asking, what has America done for medical knowledge and science?

But what of the future? The elder Gross, the Nestor of American surgery in his day, in his centennial address said: "It is doubtful if America will ever again produce at the same time four such brilliant surgeons as Physick, Mott, Warren and Dudley." In less than a quarter of a century from that time they were numbered by the scores. Observation, experience and history teach us how idle it is to indulge in prophecy as to the negative attainments of the human intellect. From the operation of laws and forces governing the past and the present, we have a reasonable basis for predicting the future. We know that the truths and acquirements of this generation are the natural endowments of the next. The ultimate fact or final reality beyond our ken is called the unknowable, but in presuming to place an absolute limit on mental capacity is itself an assumption of prescience that does not seem justifiable. "Unknown" is a better term, for it is constantly dispelled in the calcium light of a restless scientific age; though it does reveal the eternal truth that there are still "more things in heaven and earth than are dreamt of in our philosophy."

Many of the best surgeons believe that operative technic has now reached such a degree of perfection that there is little room for further improvement. In a general sense this is true. No modern surgeon now infects his patient, and in many respects it would be difficult to improve on present methods; but so long as we must adapt our procedures to new facts, improvement in technic will continue. For instance, it is only a short time since intestinal perforation occurring in 2 per cent. of typhoid cases was regarded as almost hopeless, and yet to-day from the first operative case by Mikulicz the percentage of recoveries is estimated at 25 per cent in adults and 65 per cent. in children. It is equally true that intestinal paralysis was looked on as the final stage of an abdominal disease, against which it was useless to contend; yet recent experience demonstrates that by aspiration or incision of the intestine and draining the canal, some, perhaps many, patients will be saved who certainly would have perished by ordinary methods. Our knowledge of pancreatic disease is recent. The surgery of the organ is necessarily limited, yet experience strongly indicates that its pathology is amenable chiefly to surgical procedures, and is but slightly influenced by medication. That the operative technic in these conditions will be improved there can be no doubt, as I am convinced will be the case in other diseased states whose pathology and treatment are not as yet well known. Still I believe that the professional mind of the immediate future will be occupied more with questions of preventive medicine and immunity—prevention by the formation of established medical opinion into rules and laws, and immunity through serum inoculation. Inoculation for smallpox was the beneficent beginning in 1798. The remedy for rabies, which we owe to the scientific genius of Pasteur, is the only treatment that bears good fruit, and it must be early. Since Behring produced diphtheria antitoxin in 1890, results have been revolutionized, and instead of fearing it as one of the most dreaded and fatal diseases, it is met in the confident belief, based on ample experience, that inoculation by antitoxin not only prevents, but its early use is practically a specific in the treatment of the disease. Experiments along this line to prevent typhoid fever are promising. Pneumococcic and antistreptococcic, cancer and antitetanus toxin medication are in a tentative state. The specific germs of all infectious diseases will yet be discovered; the remedy will follow, probably in serum therapy. Dun-

1. For many of the facts as to priority I am indebted to the address of Martin B. Tinker, M.D., before the Johns Hopkins Hospital Historical Club and to the American Journal of the Medical Sciences.

bar has, in the last year, demonstrated that the pollen of grasses and certain cereals is the active agent in the production of hay fever, and he has produced a serum which promises the most gratifying results in its treatment. We may hope, therefore, that in the not distant future these sufferers will not have to go to sea or climb mountain heights for relief.

With the exception of a very few diseases, we have no medical specifics, but in the future of medicine and in certain surgical states we have every reason to anticipate better results in serum inoculation.

In a brief allusion to medical education and preliminary requirements to its study, I do not intend to make invidious comparisons; but no man who is interested in his profession, its character and future, can be indifferent to the intense general interest manifested by the profession and educators at the present time. The subject, in all its phases, is most interestingly treated in the recent annual educational number[2] of The Journal of the American Medical Association, and in able addresses of physicians and educators, notably the address[3] of the President of the American Medical Association, Dr. Billings of Chicago, himself a distinguished physician and teacher. This is a plain, forceful discussion of the subject, specifically and generally, in its relation to the qualifications and motives of teachers, no less than of students, and ought to be read by all.

The Association of American Medical Colleges has recently made a high-school degree the minimum preliminary standard for medical study,[4] but as this standard varies in different communities, its value is somewhat uncertain, though it does indicate substantial progress. About one hundred of the one hundred and fifty medical schools in the United States are private. There was a time, not long ago, when the tuition of the students paid the salaries of the few teachers and the necessary expenses of these schools; but this is no longer possible in a modern school. The conditions are so different, the requirements and equipment necessarily so much more elaborate and expensive that the old era has passed away, and happily, not to return. Schools must be endowed by the individual or the state in order to meet the demand. The necessity and interests of the higher education in behalf of humanity and a more exalted professional standard should be the governing spirit and motive of those who receive, as well as those who give instruction. What shall be done to meet the recent just criticism of the long time required in getting a university or collegiate and professional education? One prominent college cuts the four years' course one year. Columbia proposes a two-year term, but it has not been accepted so far by any college. Four years in the high school, four years in the university or college and three in a law or four in a medical school is using too much time in preparation for practical business purposes. The high school and college courses are not as a rule taken seriously, and in the prevalent absence of a distinct purpose for the future, demoralization in spirit and in study and responsibility results, which further explains the idle talk that education unfits one for practical business. It would not be wise to curtail the medical course, neither is it necessary. Some of the universities propose, in the interest of medical students, to incorporate the fundamental branches of medicine in the junior and senior years, which would give two years only to the exclusive study of medicine, chiefly clinical, thus making the university and medical course six instead of eight years as at present. It is to be doubted if this is the best solution of the problem. There is a better and more practical way. In my opinion the high-school course should be cut two years. If not, any bright boy can take a preparatory course of two years and enter any college or university in America, where he may remain three or four years and enter, well equipped, on his professional studies. I believe it feasible and perfectly consistent with the future vocation of the student to cut the college or university course one, certainly, and possibly two years, thus enabling one, without a sacrifice of the classics, to get a splendid business and professional education in three or four years' less time than is required at present.

Medicine is a profession of peculiar responsibility, and requires great patience in study and preparation. No young man should wish to engage in its practice on his own responsibility under 25; but having clinical advantages, which is necessary to the best equipment, he may safely undertake it after. Johns Hopkins has the highest preliminary requirement of any medical school in the country—a bachelor's degree, with a certificate of proficiency in chemistry, physiology and physics. With this innovation a few years ago, other schools and some of its own friends predicted failure, thinking the standard too high; but under it we learn that 100 freshmen entered the school the past year. Its success was assured in a short time. There was never a substantial reform incident to human endeavor unattended with suspicion, incredulity and opposition. However costly, we know that the medical profession is ever stronger and better for them. Before seeking a medical education, it is important for the student to consider natural fitness, as well as inclination for the work; or some field of learning or labor will miss a brighter star and some man a better destiny, however seriously he may have struggled.

There are 27,000 medical students in the United States at the present time, and over 5,000 graduates annually, which, according to customary estimates, is 2,000 in excess of the requirements of population. Billings and other authorities assert that there are too many schools, too many matriculates and too many graduates. That these defects in our educational system will be corrected is manifest.

In a recent publication we find the interesting information, incident to the medical congress just held in Vienna, that in the Austrian Empire the number of medical students has decreased 60 per cent. in the last ten years, and young men are advised against the study of medicine, partly on account of the poverty of the country districts, which has forced all the best men into the cities, with consequent dissatisfaction due to overcrowding. The important fact is also mentioned that owing to sanitary and hygienic reforms instituted by the profession, the number of cases of sickness has diminished 50 per cent. in the last twenty years. This might be profitable reading for Colorado governors and aspiring statesmen interested in the organization of "medical trusts."

The laboratory, as the necessary foundation of scientific medicine and the instrument of its application to human ills, must ever fill a most conspicuous place in the medical curriculum. It was the laboratory and the scientific work of such men as Pasteur and Tyndall which appealed to the practical genius of a Lister and

2. The Journal A. M. A., Aug. 15, 1903.
3. Ibid., May 9, 1903.
4. Ibid., July 25, 1903, p. 274.

formed the basis of modern medicine and surgery. By such preparation and efforts, experimental and proved, the profession will rank second to none in scientific work and standing. More than ever a broad culture is justly deemed necessary to the best teaching and to the most accomplished work, both general and special.

The special knowledge and peculiar fitness of medical men for certain branches of the public service, both legislative and executive, is more than ever being recognized. The health of cities, communities, states and nation, food and water supply, and conditions of living are chiefly in their knowledge and keeping. Without their influence and action there can be no sound legislation affecting these interests. Without them disease would still ravage cities, schools, states and nation, and those engines of commerce and civilization, in peace and war, would turn back from every sea and every land. It must be admitted that where this influence is felt in the customs and laws of a people, there only will both health and business unite in safety, and social advancement and material prosperity reach the goal of a reasonable hope and a just expectation. The complete realization rests with the medical profession in unity of purpose and concentrated action. In Europe, if not in this country, physicians may aspire to be even statesmen. More than here they fill important offices in the suffrage of the people. Sir Frederick Treves, in the zenith of a brilliant surgical career, foregoes some of its responsibilities to enter parliament. Lister and Playfair have received its chief honors. In the present year eighteen medical men were elected to the French Senate and more were candidates. The list includes members of the French Academy of Medicine and such distinguished names as Cornil, Pozzi, Pèyrot and Jean Bayol.

We can not hope to pass good laws regulating the practice of medicine and conserving the public good without such effort on the part of the profession. Medical character, decent qualifications in those who practice and the public health demand positive and united action. No one who is fit to practice will object to it, and no enlightened citizen who respects knowledge and values character, can offer a reasonable objection. Yet we are treated to the humiliating spectacle of two governors of Colorado vetoing better laws than the one in force, and doing so practically in the direct interest of the most unadulterated charlatanism and in the spirit of that political Chauvinism, which, under the guise of personal liberty, is so often the cloak under which one hides ulterior motives and purposes; for that which is not for the good of the greatest number is usually not liberty but license. Only a Talleyrand can play this rôle successfully, and he would not employ the arts of the ward politician nor the sophistry of the demagogue. The pseudo Christian and scientist is one who, to my positive knowledge the past year (and he is representative of the class), is taken to the pesthouse and treated for smallpox, yet on returning denies positively that he has been sick. If such people are fit to make laws and to advise governors as to their duty in such matters, then, indeed, ought taxation for educational purposes to be abolished, for if ignorance is to be thus commended, we should have no use for schools and universities. But as a fact, from the office of bootblack to that of President of the United States a different rule prevails, except as to the study of medicine and the qualifications of a doctor in Colorado. If years of preparation, study and labor do not the better fit one for certain special work, then there is no virtue in knowledge, nor in the best and most humane endeavors. If utter ignorance of even the fundamentals of medicine, and the cyclical visitations of quackery, even though basking in the sunshine of science and a liberal Christianity, fits one to treat infectious diseases, and its legislative denial invites an executive veto, then where is the public safety and the vindication of learning, if not in the honor, the spirit, the conscience, the beneficent progress of modern medicine, and in that professional organization and action, state and national, now in progress, and whose influence is destined to be felt, even with those who only consider the question of votes in the determination of public questions. The governor vetoed the Sanford bill on the ground that it was in conflict with the "bill of rights" in preventing "christian" and other species of quacks from treating "contagious diseases," considering the practice by such people a religious exercise. The bill of rights guarantees freedom of speech, but holds the individual responsible for its abuse. It says that no person shall be denied any civil or political rights on account of religious opinions, but "it shall not be construed to justify practices inconsistent with the safety of the state." There is but one avenue to the legitimate practice of medicine, and that is a course of studies involving as essentials anatomy, physiology, chemistry, physics and clinical medicine. Without this preparation no person is fit to practice medicine, and no others deserve the protection of the laws. Any man who is competent to fill a distinguished public office ought to know this. The principle is recognized in the study and practice of law, of theology and of every other learned profession and practically in every known vocation except that of medicine. There is no reason and no excuse for the exception. It is a psychologic expression of conduct "that there is a natural tendency in the human mind to cast the burden of its doubts on a higher power and to relieve itself from the effort of decision and responsibility by seeking in mystery the solution of its difficulties." When a politician or official wants to do a thing for which he can give no valid reason, he appeals to the magna charta—to the bill of rights on religious freedom or to "trusts," seemingly, because one has the ring of casuistry and the other is an object of popular prejudice and distrust—as if society was not entitled to protection against vice and ignorance and the practices of those who, in the cause of mammon, usurp the sacred names of religion and science. In the ordinary business affairs of life people want those to serve them who are best qualified by study and experience. If health and life are valued as highly, one would think that the highest qualifications attainable would be as necessary and desirable. When those engaged in a calling demand the best preparation and the highest possible qualifications, it is in the interest of society and the state and should be welcomed by every enlightened people. "The safety of the state" demands a medical practice act and public health laws which are consistent with modern thought and progress.

Where enlightened medical opinion has been embodied into laws, sickness has diminished. This is the experience of the civilized world. When medical men are more numerous in legislative and executive offices, progress will be more rapid and satisfactory. The day is not distant when not only the food supply of the people but the water supply of cities and states, schools and public institutions, in fact everything that relates to the

public health, will be directly under the supervision of competent physicians. Four hundred children died in this country last July from tetanus due to accidents on the Fourth, chiefly from the toy pistol.[5] Officials and the public have for years been warned by the medical profession of this danger. When its advice and suggestions are put into laws, needless mortality will cease and the public health will be safely guarded.

Impurities and adulterations of water and foods are so common and so full of danger to the public that every good citizen should hasten and welcome the day. It is not a matter of guess work. The knowledge is at hand to control these evils and to prevent endemic and epidemic diseases, which to-day are a reproach to every civilized community, for the causes and facts being known, it is only necessary to apply them to the government of homes, cities and states, and to the conduct of life to prevent and control them.

The nation, through the United States Public Health and Marine-Hospital Service, has exhibited commendable zeal and interest in excluding and suppressing portable diseases. When officials and law-makers are made to see and admit the truth that those who speak and act from special study and experience are the most competent to judge of the conditions, and, therefore, of appropriate laws affecting the public health, then sickness will be less prevalent and will be better treated and less fatal. Then, too, the solidarity of a common citizenship, guided by enlightened opinion and just laws, will mark a new page in the cause of humanity and in the annals of medicine. If every profession does not hold up its own standard, others will not do it for it, even in a progressive age. If we are animated by the good of the many rather than the selfishness and interests of the few, opposition will wear away. The history and progress of medicine is a struggle against ignorance, superstition and cupidity. It is identified with the betterment of mankind—a profession in which is blended aspiration, ambition and the most worthy altruistic motives. Its cause is that of humanity and science, and though the few must handle the laboring oar, time will, as ever, vindicate the effort.

We appeal for just and liberal laws governing the study of medicine, and a higher, more uniform and exact standard in the requirements for study and in the qualifications to practice, knowing full well that this alone is for the general good and to the honor and dignity of a profession, whose whole life is one of labor and sacrifice for the welfare and ennoblement of man.

This was the dream of Hippocrates 2,500 years ago. Its realization is no longer a hope or a doubt. The struggle for the preservation and improvement of the best is ever on and will never end. As each heroic generation rounds out its day and enjoys its blessings, the next will take up the unfinished task and carry it on to still greater perfection. This is our heritage, our duty and our destiny. For since the sixteenth century we have not honored an idolatrous worship, but respect men for what they are and value them for what they do.

DEMONSTRATED PATHOLOGIC CHANGES FROM ALCOHOL.*

T. D. CROTHERS, M.D.
Superintendent Walnut Lodge Hospital.
HARTFORD, CONN.

Recently a new field has been opened for a study of the symptoms following the use of alcohol. The external phenomena of the functional and mental activities of the body can now be measured and tabulated with exactness unknown before. It is assumed that, if the current beliefs and theories are true concerning the tonic and stimulant action of alcohol on the organisms, it is possible to prove it by the more perfect instruments of precision. Also that theories and variable experience held so tenaciously by many persons can be tested by something more than experience, logic and intuition. The action of alcohol taken in the body can now be traced by a study of the functional activity of the senses, the movements of the heart, the muscular activity, mental vigor, temperature of the body and other conditions with a degree of accuracy unknown before. From this point of view a number of observers have taken up this problem and pointed out conditions clearly traceable to the action of alcohol about which there can be no question.

Professor Kraepelin of Heidelberg has for a long time made experimental studies with instruments of precision on the external phenomena of the body which were due to the action of alcohol. These studies have been going on for years, and recently the conclusions of some two thousand of these experiments have been published. Other observers during the last two years have repeated these experiments with newer instruments of precision, verifying Kraepelin's studies, and adding some new facts to the subject. I have made many of these experiments personally, and, in common with other observers, have been astonished that such work has not been done before. The uniformity of the conclusions indicate a range of facts that very largely explain many of the symptoms following the use of alcohol. In these experiments, only healthy, temperate persons are available. In Kraepelin's work they were generally university students and a few laborers whose lives were temperate, and whose occupation and living were uniform. Each person was examined at a certain time every day to determine the sight, hearing, taste, smell, muscular activity, heart's action, temperature, point of muscular fatigue, memory, time reaction and thought rapidity. These examinations were made daily for a period of ten or more days. The results were tabulated and the average of these examinations was put down as the normal equation of the man. Sometimes the experiments were carried on for a much longer period. The normal condition having been ascertained in this way, the person was given at a certain hour in the day midway between meals or after the time of eating, an ounce of ethylic spirits. Thirty minutes after very careful examinations were made of the senses and other conditions, and these examinations were repeated every forty minutes for a period of two or

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. S. Solis-Cohen, George F. Butler and N. S. Davis, Jr.

three hours. The second day after, a similar quantity of alcohol was given, followed by the same measurements and tabulation of all the symptoms following. This was continued every day or every second day, according to the susceptibility of the person, until ten or more examinations were made, the person in the meantime living with great regularity, both in exercise, diet and sleep. At intervals of four or five weeks, and sometimes two months, the subject was experimented on again. The results of these experiments on a large number of persons extending over several months indicated the following general conclusions:

THE ACTION OF ALCOHOL ON THE SIGHT.

If the normal vision of a healthy man will enable him to read letters a half an inch long thirty feet away, from thirty to sixty minutes after the use of an ounce of spirits these letters can not be seen at that distance, and must be brought up to within eighteen or twenty-five feet to be seen. The sight has diminished to the extent of from ten to twelve feet. The color sense was also disturbed. Colors that could be distinguished were obscured or lost altogether. The red lines had faded away and were totally obliterated. Forms and shapes were blurred and indistinct, except when seen very near. The expression of the eye was changed. Clinically, this palsy of vision so apparent in intoxicated persons, seen in the prolonged staring and efforts to concentrate the sight, is a very common symptom. This is confirmed in the experience of persons engaged in work requiring precision of vision, also in painters and photographers, who soon realize that the use of spirits seriously disturbs the accuracy of their work and hence never drink in business hours.

EFFECT ON HEARING.

The sense of hearing was markedly diminished. In health, where the sound of a watch could be heard clearly at thirty or forty inches from the ear, this distance was lessened in half an hour or more after spirits had been used. The watch must be moved to ten or fifteen inches from the ear to be heard. Thus the sense of hearing was diminished from a third to a half. Certain sounds could not be distinguished. Certain tones were confused or lost altogether. Musical sounds were greatly disturbed and confused. Extreme states of these palsies are commonly seen in the intoxicated man whose voice is always several keys higher than natural, simply because he is deaf and can not hear his own voice except by speaking in a higher key. Even the moderate drinker shows a failure of hearing in the changed tone of voice.

EFFECT ON TOUCH.

The sense of touch was also found diminished. The capacity to distinguish between heat and cold was impaired. Bulbs of iced and hot water which could be distinguished normally at a distance of an inch, after the use of spirits must be separated two or more inches to be recognized. Rough and smooth surfaces were equally confused. The distance at which they could be discriminated normally was enlarged by half or more. In some instances, hyperesthetic states of the skin appeared in the first half hour after the use of spirits, then anesthesia came on, remaining one or two hours before passing away. The first effect of spirits, giving an impression of warmth over the surface, was followed by a sensation of cold which remained a long time. The surface sensation of the body was found to be deranged a much longer time than that of sight or hearing.

EFFECT ON TASTE.

The sensation of taste was changed. Mixtures containing so many drops of bitters, salts or acids, which could be detected in health, after the use of spirits were not recognized. The quantity of flavoring substance used was increased from a third to a half more before it could be recognized. Tea-tasters and experts who depend on their ability to discriminate flavors find from practical experience that this sense is greatly disturbed and obscured by the use of spirits. The power to discriminate odors was equally disturbed, both as to quality and distance. Carbolic acid, which was readily discerned in health, was unrecognized at a short distance and only faintly perceived when brought up closely. Both the sense of taste and smell were profoundly depressed from the effects of an ounce of alcohol, this depression only passing away some hours after.

EFFECT ON MUSCULAR CAPACITY.

The effect of alcohol on the muscular capacity was tested by the dinometer and aërograph. The normal muscular capacity for lifting, pulling or pushing, also the point of fatigue, was determined in these cases. After the use of an ounce of spirits an apparent increase in this power appeared, but this always passed off in twenty to thirty minutes, followed by a marked diminution. The capacity to push with forearm seventy-five pounds or more was diminished to fifty, and sometimes more, within an hour. The power of pulling five hundred pounds dropped down to three or four hundred, also the ability to raise a weight twenty inches declined to fifteen inches in the course of an hour. The point of fatigue was marked. In a long series of experiments it was found that fatigue would follow after raising so many pounds so many feet. The arm or leg capacity having been ascertained, after the use of alcohol this was greatly diminished. Thus a person who could raise with his forearm 100 pounds in one-pound weights one foot in a limited time, utterly failed to raise half this weight in the same period an hour after alcohol was used. The fatigue point was reached in half the time and with half the work done.

EFFECT ON THE HEART.

The action of alcohol on the heart beat indicated two periods, a short stage of irritation and increased activity, followed by a long period of depression with slow recovery. Thus the heart's action was increased from ten to fifteen beats the first half hour, then there was a steady fall, in many instances the beat rate declining as far below the normal level as it had ascended above. In several instances this increased activity was very rapid. In others it was slow, but in from twenty to thirty minutes the maximum was reached, then followed a decline.

The temperature of the body showed slight fluctuations, never rising, but always falling, sometimes half a degree or less.

EFFECT ON MENTAL FUNCTIONS.

The action of alcohol on the mental functions was very marked. Thus on memory where from a series of experiments the natural equation indicated a range of 10 per cent. of failures in health, after the use of alcohol this percentage doubled. In the card test where a person seeing a set of cards was required to put down the duplicates, or where a list of names was given which the person was required to write out after seeing them a moment, a very marked palsy of this faculty appeared.

Thought rapidity and time reaction showed the same paralysis. With the aid of a battery and a clock marking the parts of a second the time was measured from the moment an object came into the field of vision to its record on a dial by the pressure on a button. This, in parts of a second, showed both the rapidity of sight and brain power of registration. If in health such impressions could be recorded in a fourth of a second from the time it was seen, after the use of spirits this time was lengthened to one or more seconds. Another experiment to show thought rapidity was to repeat words or short sentences uttered by others and registered in the same way by an electric clock. The health standard having been found, the action of spirits literally doubled the time in these cases. Numerous experiments involving reason and discrimination were made, one in which the person was asked to pick out pictures of animals and name them from a group in sight. After the use of spirits the time required was 40 per cent. longer, showing impairment both of the senses and the power of reasoning. In some experiments which I have made on simple mathematical calculations the percentage of mistakes was from 15 to 20 per cent. greater after spirits were used than before. Persons blindfolded and given tasks requiring consciousness, reasoning and correct thought were found to show very marked change and palsy after spirits were used.

These experiments may be carried on in a great variety of ways; having first found the normal condition of the person, the deviation from this can be ascertained and measured with great accuracy. During the past year Kraepelin has published some new studies, in which he has been able to recognize and measure the effects of half an ounce of ethylic spirits. This would be equivalent to an ordinary glass of one or one and one-half ounces of the common strong drink. One ounce of spirits is the ordinary equivalent of two and one-half ounces of whiskey containing from 40 to 50 per cent. of alcohol. These experiments are very significant, and seem to point out conclusively that alcohol in these doses is distinctly a paralyzer. In some work done in this country along this line where a single dram of alcohol is used, the effect on the sight and hearing was transient, but the effect on the higher brain was measurable. The difficulty in having a personal equation or normal standard from which to judge is a serious one. I have been able to point out in two cases very marked depression of the senses and brain activities from two drams of alcohol, but not having any knowledge of the person, the value of these experiments were limited.

These experimental studies are supported by clinical experience and fully illustrated in every person intoxicated by alcohol. The observations of a number of persons, including the writer, show that in all toxic states from spirits there is the same palsy of the senses and of muscular power, depressed heart's action and slowing up of the mental activities of the brain. Hence the researches of Kraepelin confirm these facts and show conclusively that the paralyzing action of alcohol begins at a very early period and from a very small quantity of spirits. It is difficult to believe that it has any other action on the nerve centers or protoplasm of the body than that of a narcotic and paralyzant.

Rice cooked with milk furnishes the most easily digested food with the largest amount of nutriment contained in moderate bulk.—*New York Medical Journal.*

THE LEGITIMATE THERAPEUTIC USES OF ALCOHOL.*

O. T. OSBORNE, M.A., M.D.
Professor of Materia Medica and Therapeutics at Yale Medical School.
NEW HAVEN, CONN.

In discussing this topic it is best to first state just what we have the right to expect from alcohol as a medicine. The desired action from a dose of whiskey or brandy or its equivalent is a warming of the surface of the body, an increased pulse tension, a moistening of the dry skin, absence of nausea, absence of much flushing of the face, absence of throbbing in the head, unless a case of syncope is treated by a large dose, when many of these primary undesired symptoms might occur. In giving alcohol continuously the dose should be regulated by the signs. If it causes flushing of the face, dry skin, dry tongue, a throbbing, bounding pulse, even temporarily, and the odor of alcohol is on the breath, the dose is too large.

Alcohol is by no means a cure-all, and, undoubtedly, in the past much harm has been done by its indiscriminate use. Perhaps, even to-day, it is used more frequently and more freely than its physiologic action warrants, and it should never be prescribed unless there is some definite indication for it. Indications for the use of alcohol may be divided into:

1. Local.
2. To stimulate the heart.
3. As a food.
4. To increase the appetite and aid digestion.
5. To relieve acute internal congestion.
6. To dilate and relax the peripheral circulation.
7. To produce sleep.
8. To combat poisons in the system.

THE LOCAL USE OF ALCOHOL.

The stronger preparations of alcohol may be applied to any part of the surface of the body as an astringent to stop secretion and to harden the tissues. For this purpose it may be used to harden the nipples to prepare for suckling, to stop profuse perspiration of the axillæ or feet, to prevent bed-sores, and weaker alcoholic preparations may enter into the composition of hair tonics to prevent too much sebaceous secretion and oiliness of the hair. Strong alcohol is hemostatic to capillary oozing. Absolute alcohol more or less constantly applied to the surface over a beginning boil, as in the ear for instance, may prevent its culmination and abort it. In concentrated form it will act as a rubefacient while being rubbed on the skin, but if allowed to evaporate it will cool the surface of the body. If diluted it evaporates more slowly and the cooling is prolonged, hence it is often used to reduce temperature. If the surface of the body is sponged with warm alcohol it is sometimes very soothing, quieting restlessness and producing mental calmness in a feverish patient. Probably a large part of the advantage of the different tinctures and extracts used for sprains, bruises, etc., is due to the alcohol which they contain. Alcohol diluted somewhat, depending on the thinness of the skin, applied on gauze or lint or lintine and covered with rubber tissue or other impervious dressing and changed every six hours, will remove the swelling

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. S. Solis-Cohen, George F. Butler and N. S. Davis, Jr.

and pain from a sprain and aid in the cure or prevention of synovitis, myositis or inflammation of the tendons quicker than most any other treatment we can institute. Diluted alcohol, one to four or five parts of water, or weaker, makes a good astringent and antiseptic mouth wash, hardening the gums and sweetening the breath. Flannel or towels wrung out of very hot water sprinkled with alcohol and placed on the abdomen or any other part of the body and changed every fifteen minutes for an hour or two causes a splendid rubefacient and counter-irritant action. A brick heated in the oven, wrapped with three or four layers of flannel dipped in boiling water and allowed to drain, and then a considerable amount of alcohol poured on it, placed beside a warmly covered patient in bed, will produce a splendid alcohol steam bath. Locally applied to the back in this form it is very efficient in the treatment of lumbago.

In the form of alcohol brandy is especially a carminative and an astringent for diarrhea, and markedly so in the form of blackberry brandy.

TO STIMULATE THE HEART.

There is a considerable difference of opinion to-day as to the value of alcohol as a cardiac stimulant. Its action on the vascular system, however, is marked and positive. The irritation which strong alcohol in any form causes on the mucous membrane of the throat, esophagus and stomach acts reflexly through the medulla to cause vasoconstriction and, hence, a rise of blood pressure, and increased blood pressure is always a stimulant to the heart. After alcohol is absorbed into the blood, where it circulates as alcohol, it can not, in my opinion, by its physiologic action on the vasomotor centers, on the blood vessels, and the heart, ever be a stimulant, although, as its secondary effect is to dilate the blood paths, this very effect of increasing the peripheral circulation may better the condition of the heart. Through, then, the irritant impact of the alcohol on the mucous membrane the blood pressure is first raised, but when it is absorbed the blood vessels dilate, especially those on the surface of the body. This relieves any spasmodic contraction of the peripheral blood vessels, whether from fear, from pain, or from chilling of the body, and this equalization of the circulation relieves any internal congestion that may be present. By this widening of the blood paths, provided no condition of shock is present, alcohol will relieve the laboring of a weakened heart. If too large doses of alcohol are given this vasodilatation goes on to partial paralysis of the blood vessels, and a weak action of the heart from this cause alone will occur. Hence, in shock where the blood vessels are widely dilated or perhaps paralyzed, either from chloroform or ether narcosis, or from morphin narcosis, or from injury or collapse, alcohol, except for its primary stimulant action in small doses, would do harm and is contraindicated.

The exact action of alcohol on the heart itself is not proved beyond a reasonable doubt. Certain it is that overdoses of alcohol after absorption are depressant to the heart muscle, to the muscle fibers of the blood vessel walls, and to the vasomotor center in the medulla. In sudden cardiac failure the reviving action of alcohol seems to me to be due entirely to the reflex stimulation of the mucous membrane of the throat and stomach. By this stimulation we cause an increased cardiac frequency and a slightly raised blood pressure from the contraction of the arterioles due to the reflex action on the medulla. This action, which occurs before much alcohol has been absorbed, may tide over the condition of acute cardiac failure, and if not much alcohol has been given there will be no future cardiac or vascular depression. If too much alcohol has been administered and absorbed the result will be to increase the previous depression unless more fresh alcohol is given for its continued stimulant reflex effect. If the previous doses are not too large and are, hence, rapidly burned or eliminated, the effect will be continued stimulation and not depression.

In conditions of high temperature where the heart is very rapid from the stimulation of the fever, from the irritation of the toxins in the blood, and from nervous irritability, alcohol, by quieting the nervous system, dilating the peripheral blood vessels, and possibly combating the toxins in the blood, generally reduces the temperature and slows the pulse. If the dose is properly regulated, this action will be found to be continuous for good. Too large doses or too frequent administration of alcohol may do one of two things: either stimulate the brain and cause more excitation, increasing the temperature by increasing muscular irritability and restlessness and causing enough of its local reflex irritation to make the pulse bounding and full, or, if it is too rapidly absorbed, it will give the symptoms of alcoholic depression on the circulatory system. Hence, in acute cardiac failure to get the stimulant effect of alcohol it must be given concentrated as exemplified by brandy, whiskey, gin, rum and champagne, and in small doses. To keep up this stimulation another dose must be given in from fifteen minutes to half an hour or an hour, depending on the continuousness of the heart weakness, in order to repeat the stimulation of the irritation. As just stated, the dose should undoubtedly be small, as the future depression from the absorption would be less than it would from large doses. If the frequency of the dose is such that alcohol piles up in the system and more is given before the previous ingested amount has been burned or eliminated, to obtain stimulation it will be necessary to give larger and larger doses, first to overcome the depression caused by the previous alcohol, and also to cause the usual stimulation. As more and more alcohol is absorbed whether from the stomach or from hypodermic injection, depression, vasomotor dilatation, cardiac weakness, and more or less paralysis of the nervous system are sure to follow. Hence, to combat continuous or persistent cardiac failure or depression, alcohol is the poorest stimulant we can use, and if much is given we are poisoning the system and adding depression to depression that is already there and the treatment is vicious.

In conditions of prolonged fever where alcohol is given no more frequently for any length of time than every three hours, one dose is probably eliminated or burned before the next one is given, and we get the primary stimulation plus the dilatation of the peripheral vessels, which equalizes the circulation and reduces the temperature.

Let me parenthetically say that I have often obtained the same good circulatory results in sthenic fever from small doses of nitroglycerin that I have obtained with alcohol.

In serious feverish conditions undoubtedly the narcotic effect of alcohol in quieting the patient, who is highly alert to his danger, may be of distinct advantage, as mental worry and anxiety are great disturbers of the

heart and circulation and should be overcome by any legitimate means.

The only time, then, that I believe alcohol can meet the indication for a cardiac stimulant is in acute cardiac failure, and then it is a stimulant to the heart only before its absorption, by the irritation which it causes the mucous membrane of the mouth, pharynx, esophagus and stomach, or the rectum, if it is given as an enema, or by the irritation of the tissues, if it is given hypodermically.

ALCOHOL AS A FOOD.

I believe that as a nutriment alcohol is uneconomical to the system and if long used is a positive disadvantage, probably even sugar being better where the amount of food obtainable is too small for the needs of the body. During feverish processes, however, as a nutriment to furnish material for the production of heat to save the tissues, fat and muscles it is of decided advantage and probably has no equal, if in such fevers not enough nutrition is taken. Undoubtedly at the present time many cases of fever are overfed. Whether whiskey or brandy should be given in every case of typhoid fever or diphtheria, or in the feverish debility of tuberculosis, or in other acute infections, is a question that each practitioner must decide for each individual case. Many such cases do well without it; many cases recover only by the use of it.

TO INCREASE THE APPETITE AND DIGESTION.

This is a very questionable indication to meet with alcohol. In occasional cases of neurasthenia, anemia, malnutrition, and inertia of the stomach, with imperfect gastric secretion, a small cocktail before meals may be justifiable and proper, but, rather than select a known alcoholic beverage for this purpose, some bitter dilute tincture will do as well, and will more readily preclude the possibility of acquiring the habit. Late in life some such stimulant to nutrition may be justifiable.

TO RELIEVE ACUTE INTERNAL CONGESTION.

After becoming chilled or getting wet or being subjected to other exposure, as the exposure of exhaustion, hot alcohol in some form combined with a hot general bath, or a hot foot bath and a warm bed, with or without a Dover's powder or quinin, is undoubtedly good treatment as tending to relieve or abort the internal congestion, whether it be nasal, pharyngeal, tonsillar, laryngeal, bronchial, pulmonary, pleuritic, nephritic, arthritic or intestinal.

TO RELAX THE PERIPHERAL CIRCULATION.

This indication for a vasodilator is present only in gouty or atheromatous conditions of the blood vessels or whenever there is too high blood pressure in the middle and late stages of life. Generally without any doubt this indication is better met by small doses of nitroglycerin, thyroid extract, potassium iodid or small doses of chloral, as well as by causing increased elimination from the skin and intestines. However, many cases occur in which alcohol has been more or less regularly taken and a small amount once or twice a day with the meals, provided the amount is such as not to cause flushing or a feeling of fullness in the head, may be of positive advantage.

TO PRODUCE SLEEP.

The use of alcohol for this purpose is only justifiable in exceptionally acute conditions or where the condition is probably not to recur, or in old people. A little nightcap of some alcoholic beverage, often, perhaps, beer, perhaps a spirit, diluted so as to prevent much stimulation, which would cause sleeplessness, just sufficient to dilate the abdominal and peripheral vessels and thus to depress the circulation in the brain, will act as a hypnotic. There are many other, perhaps, generally better methods of causing this sleep, but often the association of symptoms and conditions is such in elderly people that it is good treatment to use alcohol.

TO COMBAT POISONS IN THE SYSTEM.

It is difficult to discuss, with any reasonableness, this indication. It has long been stated, but often disputed, that alcohol in large amounts will prevent dire results from the bites of poisonous snakes. If alcohol is given in enormous amounts in the shape of whiskey or brandy the patient is soon in the first stage of alcoholic poisoning. Some acute infections in which death seems imminent have been said to have been stopped by enormous doses of alcohol, notably the final toxemia of pneumonias. The antitoxic power of alcohol in the blood against these toxins must be corroborated or disproved in the laboratory. Clinical experience in this line leaves so much room for doubt that the matter is still subject to proof.

DISCUSSION

ON THE PAPERS OF DRS. CROTHERS AND OSBORNE.

Dr. J. H. Musser, Philadelphia—I use less alcohol in my practice than I did in former years, particularly in fevers. I feel that we are employing a dangerous remedy when we use alcohol, and for moral reasons, as well as because of the doubtful pathologic results, I employ less and less of it. The indications for its use in acute diseases are those found in intoxications as arise in septicemia and for its narcotic properties. Under these circumstances patients seem to be able to stand enormous amounts, i e., in streptococcus infections, and in that type of typhoid fever seen in the aged—the septicemic type. In typhoid fever in the young, when the disease presents actual septicemic symptoms, I use it, but I prefer to use it in very small doses, and I give large doses only for a short period of time. I believe that if we withhold it and then for a short time give it in full doses we may possibly pull the patient through a condition to which he would otherwise succumb. Each year I use less alcohol, particularly in the two diseases in which we were wont to give it frequently—typhoid fever and pneumonia; here I use it only as an emergency remedy and for short periods of time. It is interesting for one to look back over his career and note any changes in his ideas. I am pretty well satisfied that I have more patients recover from typhoid fever now than ever before, and I believe this is largely due to the manner in which I handle stimulants. Of course, there are two periods in the management of this disease, in my career, the period before the bath and the period since the bath was instituted. In the latter period, in the cold water period, I find that patients get along better without alcohol than they formerly did with alcohol and no baths. Of course, this is to be expected. Moreover, under circumstances beyond our control baths can not be employed or are contraindicated. In this group of cases I use much less quantities of stimulants with better results—certainly at no disadvantage to my patients—than formerly. I believe I can say that without qualification as to the character of the disease. I think I have seen sicker people who are not put in tubs in typhoid fever in the latter period than in the time before the baths, and yet the mortality is less. I certainly can not attribute the lessened mortality to anything else because we do not use other drugs to any extent, and when we do use them it is only as we use alcohol, just as the occasion demands for a brief period and then stop.

Dr. J. A. Storck, New Orleans—We ought to try to find out the action of alcohol in carbolic acid poisoning. What is the rationale of the antidotal effect of alcohol in carbolic acid

poisoning? In a recent meeting of a medical society this question was threshed over, but no definite conclusion was arrived at as to whether its action was due to chemical change or to mere dilution. The fact remains, however, that alcohol is the ideal antidote for carbolic acid poisoning.

DR. W. J. ROBINSON, New York—In reference to the statement by many physicians that they are using alcohol less and less each year, I have no doubt that a good many do use less, but I come across some who think they use less, yet in reality they do not. For instance, a number will give liquid peptonoids and other preparations under the impression that they are not giving alcohol, and yet we know that these things contain from 20 to 25 per cent. of alcohol, so that when a physician gives 8 ounces of liquid peptonoids he gives about 4 ounces of whisky. This is, of course, not true of all physicians, but it is a fact in many instances. In reference to septicemia, especially puerperal septicemia, I do not believe there is any drug equal to alcohol. As to alcohol and carbolic acid, there is a true chemical reaction. This is a fact; it is not a simple dilution, because we can not get the same effect with water, even if the latter be used in 100 times the amount. Experiments have been made in this direction on the outside of the body, and it has been shown that alcohol completely neutralizes the carbolic acid, and probably the same effect is obtained in the body.

DR. J. H. MUSSER, Philadelphia—I do not bother with panopeptone and such preparations except in cases in which we can not give food by the stomach. It is a class of remedies that I consider pernicious.

DR. A. C. CROFTAN, Chicago—Few people realize that alcohol has been demonstrated to be a normal product in the disassimilation of sugar. I have done some work along this line. If you take a large quantity of human muscle, or pancreas, for instance, and, under certain technical precautions, distill it with water you will get an appreciable quantity of ethyl alcohol. The knowledge of this would probably horrify the temperance advocates. From a purely physiologic standpoint this may indicate that a small quantity of alcohol is probably a physiologic stimulant.

DR. S. SOLIS-COHEN, Philadelphia—Are the sulphates a better antidote to carbolic acid poisoning than alcohol?

PROF. C. S. N. HALLBERG, Chicago—The alkali sulphates have always been regarded as the chemical antidotes because the double decomposition forms sulphocarbolates, but alcohol has certain effects which can not be obtained by using the sulphates. In addition to alcohol, camphor has a modifying effect on the carbolic acid, so that their combination, as in spirit of camphor, would probably be more effective.

DR. S. SOLIS-COHEN, Philadelphia—I am one of those who, like Dr. Musser, do not use disguised forms of alcohol, and yet I am conscious that my resort to alcohol in acute febrile affections, and especially in typhoid fever, has been lessening steadily. In fact, I never think of prescribing it, unless some special condition calls for it; in other words, I use it as I would use opium or any other drug, in specified dose for a special purpose.

DR. T. D. CROTHERS, Hartford, Conn.—We have reached a point in experimental researches where certain facts can be demonstrated with a reasonable degree of accuracy. All assertions concerning the action of alcohol on the body should not be accepted to-day, unless they have been subject to some scientific test and critical examination. The clinical fact that alcohol is an excellent refrigerant in fevers when used externally can be confirmed with great exactness and traced to the rapid water-absorbing property of alcohol. When alcohol is used as a stimulant and tonic, scientific experiment fails to point out the evidence necessary to sustain this assertion, hence such theories are only vague unsupported inferences. While it can be shown that alcohol acts most positively on the heart and vasomotor centers, both increasing and slowing up the organ and the circulation of the blood, the effect of this peculiar action is unknown, and until more accurate researches are made we must regard this action as more or less dangerous. Any remedy which disturbs the nutrition and the rhythmic flow of blood through the brain should be used with great caution. The known effects of alcohol on the senses, blood vessels and heart are very limited compared with the unknown, and yet this little knowledge is startling in the clearness with which it points out the corroding action of this agent, together with other effects not yet studied. The toxic action of alcohol, either in small or large quantities, falls most seriously on the blood vessels and heart; beyond this stretches a wide unexplored country. My paper is simply a contribution to the work that is to be done in this direction, and also an indication of how wide the domain of exact studies are.

DR. O. T. OSBORNE, New Haven, Conn.—I wish to emphasize the fact brought out in the paper that we have been using alcohol during all of these years as a cardiac stimulant in fevers, and we come to find out that it never acts as a cardiac stimulant, but that it acts as a vasodilator, and hence is of value in sthenic cases. I have seen nitroglycerin effect the same good results as alcohol. Cirrhosis of the liver caused by overuse of alcohol simply bears out the fact that continued irritation of any organ sooner or later tends to produce connective tissue in that organ.

NASAL POLYPUS; ORIGIN AND TREATMENT.*

CHAS. H. BAKER, M.D.
BAY CITY, MICH.

There is a variety of growths within the nasal chambers to which the name polypus has been given, and much confusion has arisen in consequence, both in regard to the origin and frequency of nasal polypus. Those who restrict the term nasal polypus to the gelatinous form find them comparatively infrequent compared to the total of nasal disorders, while others, like Zuckerkandl, who included posterior turbinate hypertrophies and fibro-adenomata, claim that they occur in every eight or nine autopsies.

It is my purpose to confine this paper to the discussion of the true nasal polypus or gelatinous myxoma, although what I shall say as to their causation will apply largely to the other growths which have been classed as polypi.

ORIGIN.

True nasal polypus has by different pathologists been classed among the adenomata or the myxomata according to whether one or the other elements predominated in the structure. The prevailing type is that of a pure myxoma with delicate connective tissue stroma, few vessels and made up principally of the characteristic stellate myxomatous cells imbedded in gelatinous intercellular substance, chiefly mucin.

There are certain variations according to location, life history and presence or absence of outside interference or irritations, and many are found with much connective tissue and glandular structure replacing the ordinary mucous contents. The fact that mucous polypi seem occasionally to undergo cystic degeneration indicates that they may be partly glandular in origin, but true cystic degeneration of the mucous polypus does not occur.

By far the majority of polyps spring from the anterior edge of the middle turbinate or from the edges of the hiatus semilunaris; next from the upper and posterior portions of the middle turbinate and, lastly, may be found in the interior of a bullous middle turbinal or about the outlets of the accessory sinuses. Very rarely they have been found in other localities, but when so

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

found have belonged to the type which I have excluded from the designation of true nasal polypus.

Bosworth has said: "It is difficult to assign any definite cause for the occurrence of nasal polypus. They are certainly not due to any impairment of the general health or constitutional diathesis, for, as a rule, they occur in patients in vigorous health." Sajous says: "They are usually considered to be due to a chronic inflammation of the schneiderian membrane."

Mackenzie[1] has controverted this view on the ground that polypus is rare in children under the age of sixteen, while catarrh is very common during those years. This is a strong argument in favor of my contention that they are produced by suppuration in the accessory sinuses, which, as we all know, are rudimentary until that age.

Bosworth inclines to the view that as the middle turbinate is chiefly concerned in osmosis in the nasal chambers the membrane is liable to become water soaked from the action of gravitation and traction from the inspiratory effort. He says: "As to what peculiar nutritive disturbance in the meshes of this tissue predisposes to this form of degeneration I have no explanation to offer."

Billroth believed them to be due to the occlusion of the ducts of some of the glandular elements and consequent mucoid degeneration, which was the view adopted by Zuckerkandl. They all just miss of an explanation which explains the occurrence of polyps in the case of fracture of the vomer mentioned by Gerdy or the frequent occurrence in cases of syphilitic ulceration where polyps spring up along the edges of the lesions; or their growth from the edges of the healing stump of a middle turbinal after removal of the latter.

SYMPTOMS.

When first forming, polypus manifests its presence by intense irritation of the mucous membrane with usually a profuse watery discharge, but when well established the membrane often becomes so tolerant of the pressure that there are no symptoms except those due to the interference in respiration. This is due, I think, to the subsidence of the violence of the initial suppuration rather than to tolerance to the pus.

As the growth increases there is a sense of obstruction to respiration out of proportion to the interference with the passage of air, undoubtedly owing to the irritation in the region of the middle meatus, which is the principal respiratory channel. The sense of smell is early interfered with owing more to the degenerative changes than to any mechanical interference with the impact of odorous particles on the schneiderian membrane.

The stenosis varies considerably with the dampness of the weather, some have supposed owing to their being hygroscopic, a view which is hardly tenable. Is it not rather due to the difference in the total atmospheric pressure on the body surface and the slower adjustment to this pressure by tissue of such low vitality and without muscular elements?

The nasal mucous membrane is intensely irritable in the presence of polypus, one small growth often causing as severe a paroxysm of asthma as does a whole noseful. There is persistent hyperemia co-existing with nasal polypus which induces great sensitiveness in the nerve endings, making them extremely sensitive to temperature and barometric changes, which irritability is, in turn, reflected back onto the general nervous system, and patients suffering with polypus are, therefore, peculiarly subject to reflex disturbances with every change of the weather.

Polypus is accompanied by profuse nasal discharges which are chiefly mucoid when the causative accessory sinus inflammation is quiescent, but quickly become purulent on slight provocation.

This brings me to my chief contention that nasal polypus is the direct result of suppuration in the cells or sinuses communicating with the nose, or inflammation of the periosteum covering the middle turbinate dependent on previous purulent inflammation within the bone itself. Nasal polypus is like granulation tissue from any mucous surface differentiated by the local modifications of the membrane lining the nose. It is like granulations elsewhere—the expression of the natural efforts at repair of tissue under the stimulus of irritating pus discharges.

We are often first called to see polypus when fully developed and when the sinus inflammation has subsided and find only bland mucous discharges. Some have concluded that when pus does accompany polypus it is the result instead of the cause.

The only way to know what is the true connection is to study the cases of small and embryonic polypus and diligently inquire into the history of each patient with full-grown specimens, when it is often easy to trace the inception to some unusually obstinate cold with prolonged flow of pus or to some systemic disorder like typhoid fever.

Solutions of continuity of the mucous membranes are very common in these conditions, and the flow of pus from a diseased sinus over the raw surface is very apt to produce what a similar flow produces in other parts, as a discharging ear, a healing mastoid or wound in other regions, namely, excessive granulations. "Proud flesh" does not occur in all wounds; neither does polypus occur in all suppurating noses; but the latter happens in as fair proportion to nasal suppurations as does excess granulation in the former.

All noses are liable to purulent inflammations, but not all have polypus any more than all scarlet fever cases have nephritis, or diphtherias are followed by paralysis. Syphilitics, either primary or secondary, are more prone to polypus formations than are healthy subjects, and the lymphatic temperament also seems more liable than the other constitutions. I do not know whether my experience is unique, but I find the Germanic races oftener the hosts of polyps than others in about the proportion of two in three of my total cases, and I do not think this is due to any preponderance of these people among my patients, as this is not the case.

As has been stated, nasal polypus originates chiefly from the nasal portion of the ethmoid, and suppurations occurring as they do in the accessory sinuses and cells tend to produce irritation of this bone and the mucous membrane covering it, owing to its position in close apposition to the outlets of these sinuses where it is exposed to the emerging pus before it is diluted with the nasal mucus.

For these reasons polypus is chiefly found on the membranes most closely in touch with the outlets of the sinuses and cells, and the natural flow of pus and mucus being backward into the pharynx, both the inferior and superior turbinates are out of the way of the greater part of the irritation.

The upper turbinate lies too high to be reached by the downward flowing pus, and the lower turbinate seems

1. Bosworth, 1889, p. 391.

to be more resistant than the middle, although the rear end over which more pus flows is subject to a form of degeneration which simulates polypus as closely as the difference of structure permits.

Nasal polypus has been found on the septum and the superior portion of the middle turbinate, but so far as I have observed it never occurs in these localities except when there are masses of polypus filling all the available drainage spaces and damming the flow of pus back so that these parts which usually escape are bathed in the irritating secretions.

I have called attention to the fact that polypus is practically unknown before 15 years of age, not because suppuration does not occur before that age but because the sinuses are comparatively undeveloped before that time; the nasal chambers are much simpler and, therefore, drain much easier, and suppuration is oftener due to adenoids than to any other cause up to that time. The discharges from the nasal chambers of children are more mucus than pus, and we seldom see the clear pus of sinus disease issuing from their noses, which is so common in adult life.

Polypus causes a variety of disturbances both locally and of the general system. The gravest of these are asthma and hay fever, which follow up their unfortunate victims year after year and make life a burden to them. So common have I found polyps in asthma that I always feel a sense almost of personal injury when I run across a case in which they can not be demonstrated; for the relief and usually cure which follows their complete removal is so certain I feel as if deprived of part of my deserved gratitude and triumphs when they are not there to be removed.

DIAGNOSIS.

Of the diagnosis I should not feel it necessary to speak if I had not so often seen mistakes made by good men who were fairly well versed in diseases of the nose, and even mistakes by men one had a right to expect better things from.

The glistening whitey gray of a polypus is like nothing else which is to be found in the nasal chamber unless it might happen to be a smooth pledget of cotton covered by a thick flow of mucus. It is never so pink as the turbinates, and to the probe it has a soft elastic, slippery feeling which is quite *sui generis*. To examine a nostril satisfactorily for nasal polyps the surfaces need to be cocainized and adrenalin chlorid applied in order to give access to as much of the nasal chamber as possible and then a very flexible probe used in order to accurately locate the point of origin of each growth.

When this has been done the polypi stand out glistening white and can not in any case be mistaken. There is a condition of the lower turbinates which superficially resembles polypus, but if it is remembered that polypi do not occur on this part of the nose, and if the method outlined above is followed, no confusion need arise. In this class of cases the lower turbinate is unusually anemic and looks water soaked, but under the adrenalin it shrinks and tightly hugs the bone, while polypus is not much, if any, altered in size or appearance.

Beside the disorders already named, there is a peculiar bronchial reflex cough which resists all ordinary remedies and which is akin to the like cough occurring in children who suffer from adenoids. This cough resists all treatment except removal of the polyps, when it usually abruptly subsides.

The prognosis as regards life is not especially unfavorable, but many an unhappy victim of asthma would almost welcome death as a relief from the suffering when in the midst of a paroxysm. It is quite generally believed that polypus may undergo sarcomatous degeneration, but the most that can be said is "not proven."

TREATMENT.

I come now to the subject of treatment, and to my way of thinking there is but one method.

Having located the base of the growth with the aid of a head mirror and a good light, encircle the growth in the loop of a good snare, and with the cold wire cut it off as near the base as possible. It is sometimes necessary to cut through the middle of a polyp in order to secure room to work, but with a proper snare this is rarely necessary, as the loop can be insinuated up to the base in most cases and there is little or no hemorrhage excited. This is a distinct advantage, as it allows continuing work with slight interruption until the whole cavity is clear.

Adrenalin also prevents most of the bleeding and greatly facilitates the work. Working from below and from before backward the nose can usually be sufficiently cleared for fair respiration at a single sitting, and the patient experiences such relief as encourages him in continuing to the completion of the treatment.

Allowing three or four days to elapse after the first removal, on the second sitting one is often surprised to see the nose almost as full of polyps as at first: a number of them, which had been securely hidden in the recesses of the nose, coming down into sight as soon as pressure is removed. When all polyps have been removed which careful search with the flexible probe will reveal, if the patient is one who can be relied on to return for occasional examination, it is well to wait for developments to see if there is any return. But if there was a large number of the growths, especially of tiny ones all along the middle turbinate, and particularly if in the course of the removal you uncover a well of pus which flows out freely; or if the case is one in which there has been return one or more times after complete removal, it becomes necessary to resort to more radical measures.

Bosworth has said: "I can not think there is any condition which warrants removal of the middle turbinal for the cure of nasal polypus."

Had he done this as often as I have he would never have written thus, for in the kind of cases I have enumerated I have always found two or a dozen polyps in positions which were totally inaccessible until either the anterior or the whole turbinate had been amputated. No cure of asthma is to be expected so long as there is a single polyp remaining, and I hold it is better to do the harmless removal of a middle turbinate once in a while when it was not absolutely unavoidable than to err by allowing many patients to go uncured when failure lay in the undiscovered and, therefore, unremoved polyp hidden behind or within a diseased middle turbinate.

From observation of a very large series of cases I have reached the conclusion that it is impossible to cure a case of polypus so long as there remains a suppurating sinus to pour its pus over the site of their growth or a diseased middle turbinate on which the growth can occur. I therefore always remove the whole middle turbinate in cases of recurrent polypus suffering from any reflex disease.

Of other methods than the cold snare I do not care to speak except to condemn them as inefficient, and as for cauterizing the stumps after removal, it is not needed if the underlying cause is recognized and removed, and if not then it can do nothing but harm.

In conclusion let me say: Nasal polypus is in effect the same thing as granulation tissue, being produced in the same way and by the same causes as granulations elsewhere; complete and permanent removal is necessary to the cure of various reflex disorders induced by their presence; obstructed sinuses filled with pus are most commonly the cause of failure to cure, and to relieve these and secure proper drainage removal of the middle turbinate is often required; and lastly, the middle turbinate requires removal in all cases of persistent recurrence on its body.

DISCUSSION.

Dr. Robert C. Myles, New York—The name "polypus" is very unfortunate, and to change it would be an advantage for those who come after us, especially in regard to treatment. Nearly all of our distinguished writers assert that this is a myxoma, but I think it has been proven beyond any doubt that it is not; it is not neoplastic but is simply an infiltration. Then we approach the idea of it being a mere dropsical condition. Admitting that, how does the dropsy occur? It may occur from several different sources, but usually it is due to the pressure of some inflammatory deposit on the vein. A polypus is only an enlarged mass which has occurred in this way. I think we spend a great deal of time unnecessarily digging around without removing the middle turbinate in many of these cases. In the removal of the middle turbinal in a great many cases I have never seen any very serious evil consequences.

Dr. H. W. Loeb, St. Louis—Dr. Baker stated that the cold snare is the only efficient method of removal of polypi. Of course, the cold snare is highly efficient, but there are some other methods that are also of service. For instance, the electrocautery snare, with which I have removed 107 polypi at one sitting, should be considered efficient, at least to this extent. I agree that the middle turbinate must be eventually treated, and I meet the eventuation of treatment at the time I remove the polypi. I do not waste any time with the snares, either cold or hot, unless they are absolutely necessary, but I use the forceps and work as rapidly as possible. I think we must look on polypi as a surgical rather than a nasal condition. We do not waste time with a snare in taking off similar enlargements elsewhere.

Dr. S. G. Miner, Detroit—I must take exception to Dr. Baker's statement that polypi are rare under the aged of 15; in Detroit we often find them under 12. The method of operation just described is not always satisfactory. After removing the polypi we will frequently find a great deal of granulation tissue under the middle turbinate and a thorough curettage of that part with the subsequent application of trichloracetic acid is very advantageous. If the inflammation does not subside and there be any pressure from the lateral wall on the middle turbinate, then I think a turbinectomy is necessary. But I do not think a turbinectomy should immediately follow the removal of a polypus.

Dr. C. M. Cobb, Boston—This is a surgical condition and it is necessary to remove the tissue that is diseased. If the nasal polypi are an evidence that the sinus is diseased, which I believe is very often the case, then the granulation tissue in the infundibulum is also an evidence of disease. I want to take issue with Dr. Baker as to the positive association of sinus disease and adenoids. The sinus disease may be the cause of the adenoids and the removal of the adenoids may not suffice to cure the rhinitis. Indeed, I do not believe it will cure more than 50 per cent. of the cases.

Dr. F. W. Hilscher, Spokane, Wash.—I also look on this disease as a purely surgical one. I make the same preparation as Dr. Baker has described and then I attack it with whatever instrument is at hand. Sometimes I use the snare; frequently I do not. Often I reach in with the alligator jaw forceps and cut it off with a curved scissors and then with Dr. Myles' beautiful trimming forceps I trim it off very closely, frequently including the point from which it grows, and then cauterize the base with the electrocautery.

Dr. Charles H. Baker, Bay City, Mich.—I do not consider any method efficient that takes the time and fussing that the cautery takes, compared with the time the cold snare requires. We all know how very flexible the wire of the galvanocautery is and it is often impossible to insert the wire in these cases. A wire of some resilience must be used or we will be forced to waste time and do poor work by what I have called fussing. The polypus is a symptom, I believe, of a previous purulent inflammation in the nose. Detroit is rather uniquely situated, and it may be that polypi occur more frequently there in young individuals. but I have found mistakes made in cases that have come from Detroit, and they were not the kind that Dr. Myles referred to that may have a polypus in Buffalo but not in Pittsburg.

THE WINDOW RESECTION OPERATION

FOR THE CORRECTION OF DEFLECTIONS OF THE NASAL SEPTUM.*

OTTO T. FREER, M.D.
CHICAGO.

Since publishing my first paper on this subject in March, 1902,[1] I have added 36 operations to the 15 reported at that time, making a total of 51.[2] Of these patients, 31 were young adults, 10 people of middle age and 10 from 12 to 17 years old. There were 43 men and 8 women. In 25 cases the deviation was in the left naris, in 23 in the right, and in 3 in both, the deflection being sigmoid anteroposteriorly; 7 deviations followed the entire septum from the tip of the cartilage almost to the posterior border of the vomer; 19 deflections were purely cartilaginous; 28 required removal of both bone and cartilage; 4 were entirely or mainly bony; 23 were of even normal thickness, while 4 were evenly thin, the cartilage being as thin as a visiting card; 12 had a thick bony base, which projected upward and usually strongly outward toward the lower turbinal. In 13 cases the cartilage was thick, averaging one-fourth of an inch through. On 3 deviations only were there exostoses and ecchondroses. In 2 there was absence of

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards. O. Joachim and G. V. Woollen.

1. The Correction of Deflections of the Nasal Septum with a Minimum of Traumatism, The Journal A. M. A., March 8, 1902.

2. Addendum. Nov. 12, 1903.—Since writing this article I have performed the operation in 9 additional cases, making a total of 60. Of these 9, 7 were angular deflection, 1 bowed and 1 crest-shaped. In 5 of these the obstruction in the nostril was complete, or nearly so; 4 deviations were cartilaginous, 4 osseocartilaginous, and 1 bony; 2 deflections were in the right naris. Two of the operations were performed on children aged 8 and 10 respectively. Combined local and chloroform anesthesia was used, the general anesthesia being carried only far enough to keep the child unconscious of its surroundings, so that it did not even reach the stage of half narcosis. The local anesthesia entirely controlled the pain, the chloroform being employed merely to keep the child quiet. The slight flow of blood was readily swabbed away and the little that flowed back into the pharynx was swallowed, as the superficial general narcosis did not abolish the reflexes. The use of the Kirstein light made the operation in the recumbent posture easy and a number of the later operations on adults have been done in this way for the comfort of the patient. One small perforation occurred. It was only of pinhead size, and was made in operating on a septum that had been subjected to operations by three rhinologists, the resulting cicatrices making the dissection of the mucous membrane very difficult. All of the cases recovered without complications and with perfect patency in the obstructed nostril. The new nasal speculum of Monosmith (described in The Journal A. M. A., April 4, 1903, page 916) has proven itself very useful as an adjunct to the retractors because the vertical opening of its blades lifts the nasal tip and leaves the operative field unobstructed.

cartilage over a small area, the mucous coverings being in contact. Thirty-seven deflections were of the type called angular, while but 6 were bowed, 5 atypical and 3 sigmoid. Thirteen presented a dislocation of the anterior inferior angle of the quadrangular cartilage from the cutaneous septum so that the anterior end of the cartilage lay across both nostrils. Six deviations seemed to be large exostoses, but proved to be hollow, bony deflections. Thirty-six deflections began in or near the front of the naris, while 15 began in or near the bone. There were 14 large bony deviations reaching nearly to the choanæ. In 5 cases the cartilage was removed extensively from the anterior inferior angle of the quadrangular cartilage to the bony septum.

The operations caused 9 perforations of the septum, 7 of about the size of a pea, and 2 as large as a 10-cent piece. They were all more than an inch back in the naris, and none caused the patients annoyance. Six of the perforations were made in the first 15 operations. Since then improved instruments and greater experience have reduced the number to 3 perforations in 36 cases. Secondary hemorrhage occurred in 2 cases, in one two hours after the operation, and in the other in one week. The bleeding in both cases was severe, but not dangerous.

This summary shows that a number of people at the end of childhood endured the operation, and in none of my cases was unusual fortitude required. A medical student told me that he suffered less from the removal of his bony and cartilaginous deflection than during dental operations lasting as long, and patients may be assured that the operation is but slightly painful. The cutting away of bone and cartilage is readily borne as long as no attempt is made to break them over. In my series the cartilaginous deflections were outnumbered by those containing bone in the proportion of 19 to 32. Classed with the latter are only those needing actual operation on the bone, and usually it was difficult to tell whether there would be need of this until removal of the cartilaginous part of the deflection exposed the bone to view. A merit of the resection operation is the possibility of clearing the nostril at one sitting of obstructing bone, as well as cartilage. In the 13 thick cartilaginous deflections mere straightening of these would have given but partial relief, as the thickness of the septum itself in these cases formed an obstruction. An advantage of the resection method is that at the point of greatest narrowing of the naris it creates the utmost possible space by not only straightening the septum, but reducing its thickness to that of the two layers of mucosa. This fact very often makes extensive resections unnecessary, as a small window in the cartilage or bone suffices to free the naris completely.

Exostoses and ecchondroses rarely—in but 3 of my cases—complicated the deflection which was, as a rule, of nearly even thickness. The skeletonizing of the deflection in the resection method gives a perfect insight into the structure of the septum, and many deviations that at first seem to be exostoses, or form their base, prove to be evenly hollow bony deflections when entered. Their concavity lies far back in the naris and may be invisible, so that should the surgeon saw off the supposed crest he will find that he has made a large perforation.

The angular far outnumbered the bowed deflections, and no matter what their form in the cartilage, the bony portion of the deviations nearly all had a typical shape, that of a wedge-shaped projection ascending upward and backward in the direction of the upper border of the vomer. The inferior wall of this hollow wedge anteriorly often lay so close to the nasal floor that it was liable to be overlooked in the operation, while in most cases posteriorly the deflection rose to above the level of the inferior meatus so that it pressed against the upper part of the lower turbinal and filled the middle meatus.

I found great variations in the thickness of the mucous membrane covering the septum. In some cases thick mucosa included cartilage no thicker than an egg shell, and in one case the mucous membrane proved to be the main obstruction to breathing, as it was three-sixteenths of an inch through. In other instances it was so thin that instruments could be seen underneath it.

In no case operated on, even when the deviation was removed from the anterior tip of the cartilage far back into the bone, was there any damage to the nasal profile, but where the nasal tip had a twist to one side this deformity was often lessened or removed. This proves that the external nose does not need the support of the septum, but that its own cartilages maintain its shape.

The operation as performed now by me is in principle unaltered, but many changes in the details have led me to describe it again. The patient is seated in a chair with an adjustable head-rest, so fixed that it advances his head within easy reach of the surgeon. The light preferred by me is the Kirstein electric headlight, as it makes the operator independent of a fixed light for reflection and because its rays are parallel to those entering the eye; hence it lights the naris to its deepest part. It permits the surgeon to operate with the patient lying down should he need to be placed on a table if he feel faint while sitting. It also makes operations on children in general anesthesia possible.

For local anesthesia I still use powdered cocain, applied to both sides of the deflection with a small damp swab, and toxic symptoms of consequence have never resulted from the drug. Faintness occurred in only 4 cases during the operation; happened early in its progress, passed off long before its end and was due to fear rather than cocain, as the use of this was continued. In most cases, adrenalin made the field of operation bloodless or nearly so, but often failed to act. Applied to bleeding wounds it was not as good a hemostatic as a fresh application of cocain. Before the operation the vibrissæ are cut away and the nasal vestibule is cleaned with a damp swab. In deviations far forward, the ordinary nasal specula can not be used, and instead an assistant lifts the rim of the nostril in the desired direction with a flat retractor or two retractors. For operations further back the regular specula are suitable. Blood is wiped away with cotton swabs on pointed applicators, numerous to avoid delay, for, though the bleeding is never great, a little blood obscures the field of operation.

The first incision cuts through the mucosa only, along the vertical angle or summit of the cartilaginous deflection, which is usually vertical in direction, but may extend obliquely upward and backward. The vertical incision is joined by a horizontal one beginning about three-fourths of an inch behind it and carried along the bottom of the septum forward to beyond the beginning of the deflection. In this way an anterior and short posterior flap are outlined to meet at the vertical crest of the deflection, the incision forming an inverted T (Fig. 1). These cuts are made with knives having small blades with half-round edges (Fig. 8, B, C, D). The blades are placed straight on the shank or at an angle on the flat to cut vertically deep in the naris and their

small size permits them to enter narrow spaces. It is important to outline an anterior flap large enough to completely uncover the cartilage of the deviation in front and above, and to be caught with and held out of the way by the retractor, or by a light catch forceps.

The mucous membrane can not always be separated from the cartilage by blunt dissection; and is usually most adherent in front. Where it is firmly attached it must be dissected off, and for this I use two small, flat knives with rounded, paddle-shaped, thin, sharp blades. One of these is bent on the flat in order to dissect from the vertical incision forward (Fig. 8, E—I.)

Fig. 1.—Lateral view of nasal septum with angular deflection. Dotted line a-a, vertical; b-b, horizontal incision through the mucous membrane.

The anterior flap should be detached to the limit of the outlining incisions, fully uncovering the front of the deflection. The posterior flap may also need to be dissected off for some distance back, but usually may be lifted from its attachment with a thin, dull-edged, steel dental spatula (Figure 8, M.). The separation should be carried under the mucosa as far back as the deflection reaches, behind the limit of the posterior flap. This detaches the mucosa completely from the convex side of the deflection, leaving

Fig. 2.—The same as Fig. 1, showing the anterior and posterior mucous membrane flaps reflected, exposing cartilage of deflection to view. a-a. Dotted line showing slit cut through cartilage at front of deflection. The separation of the mucosa from its attachment is continued as far as the limits of the shaded area, showing the extent of the deflection.

it only attached above and below, behind the limit of the horizontal incision. It may be necessary to continue the latter to the end of the deflection where this extends far back, and thus sever the mucous membrane from its attachment to the bottom of the septum along the whole length of the deflection in order to get room to work in. It is better to avoid this, however, as the mucosa applies itself much better during healing if left attached behind as much as possible at the bottom. The object in creating a short posterior flap by continuing the horizontal cut back of the vertical one is to gain room for manipulation.

When the entire deviation on the convex side is bared of mucosa a vertical slit is made through the cartilage in front of the beginning of the deflection, underneath the anterior flap, along its anterior attachment (Fig. 2). The cut must not pierce the mucous membrane in the opposite nostril. If it be made within, instead of in front of the anterior part of the deflection, that is, too far back, a portion of the deviation will be left to obstruct the foremost part of the nostril. This occurs most easily where the tip of the quadrangular cartilage lies across both nostrils as it usually does in deflections far forward. If not removed in the first place the obstructing strip of cartilage remaining in front has to be dissected out from behind toward the operator. This is so difficult that it may have to be removed from the other nostril by dissection at a later operation.

The anterior vertical slit in the cartilage is made with a round-edged knife (Fig. 8, D, or B, C), as the sharp-pointed knife I used formerly is prone to

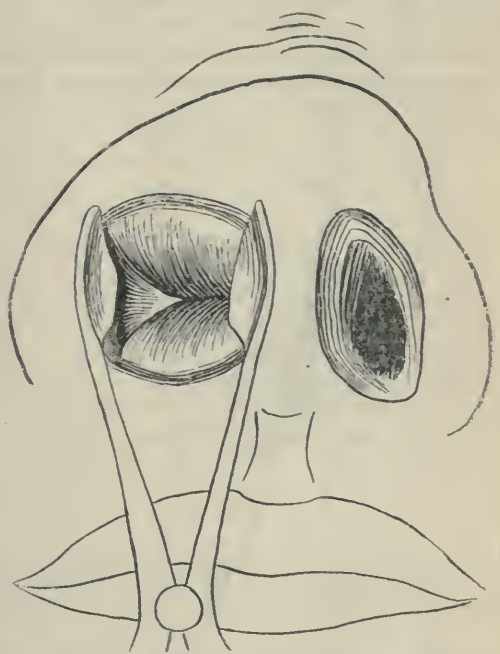

Fig. 3.—View of the concavity of a deflection.

prick through the opposite mucosa. The left little finger is introduced into the nostril opposite the deflection in order to feel the edge of the knife before it can cut through the mucous membrane after severing the cartilage. Should it make a little cut through the mucosa this will be closed when the anterior flap is replaced. Operating in the right naris is harder than in the left, as it is necessary to cross hands in order to place the little finger of the left hand in the left nostril, unless one can use the left hand for cutting.

The dental spatula (Fig. 8, M), is now pushed through the slit and under the cartilage, between it and the opposite mucosa, which it separates over the entire extent of the hollow of the deflection by severing its adherence submucously. The instrument may be watched from the naris of the concavity as it moves beneath the mucous membrane, and when this is completely lifted off the concavity appears effaced (Figs. 3 and 4). When the mucous membrane is too adherent punctures through it with the spatula occur when force is used to separate it. In these cases the posterior edge

of the severed cartilage in the slit should be seized with rat-toothed forceps, pulled outward and the mucosa of the concavity dissected from its attachment with the round, flat knives (Fig. 8, E, I), or sharpened dental spatula (Fig. 8, L) until a place is reached where the adherence is slight and the dull spatula may then be used again. If any mucous membrane remain attached it will tear through when the cartilage is removed, therefore it is important to lift all the mucosa from the concavity, especially at the thick bony base of the deflection where adhesion is greatest.

The deflection is now bare of covering on both sides or skeletonized. Ingals' pointed cartilage knife (Fig. 8, H) is now inserted in the slit and under the cartilage, passed to the back of the hollow of the deflection and with its point turned outward from the mucosa made to cut through the entire length of the cartilaginous deflection along its base. The deviated cartilage is now free at the bottom and in front, and to cut it away at the back and above it is firmly held with rat-toothed forceps, while one of the little sharp-pointed angular cartilage knives (Fig. 8, J, K) is passed under the cartilage to the very bottom of the pocket formed by the hollow of the deflection and its separated mucosa, its point also turned outward, away from the mucosa of

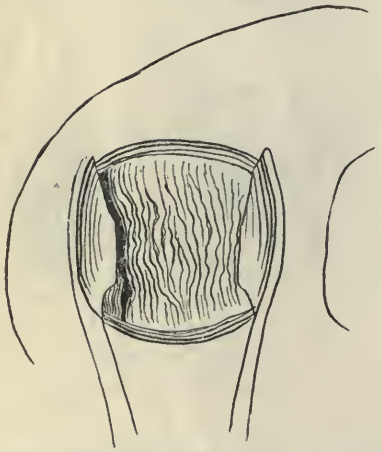

Fig. 4.—Same as Fig. 3, showing the disappearance of the concavity of the deflection from view after the mucous membrane has been separated from the cartilage through the slit made from the opposite nostril.

the concavity and the blade made to cut through the hindmost part of the cartilaginous deviation at one sweep from above downward (Fig. 5). The second little angular knife is passed in in the same way and made to cut through the limit of the deviation above from behind forward. In this way all or nearly all of the cartilaginous deflection may be removed entire, including the angle. For thick cartilage I use a pair of angular cartilage knives with longer blades (Fig. 8, F, G.).

After exsection of the piece of cartilage the inner surface of the mucosa of the concave side may be seen framed with white, cut edges of cartilage (Fig. 6). Remaining deviated portions of this are cut away with the little angular knives or the punch forceps of Gruenwald. All parts that jut out from above and keep the flaps from lying flat against the septum should be removed, and the base of the deviation, which usually projects upward and outward as a thick, partly bony ledge must be chiseled, gouged or trephined away or cut away with the punch forceps. The flaps may then be replaced if the deflection be purely cartilaginous and the operation is done; the turbinated bodies previously hidden by the deflection appear to view, the breathing through the nostril is noiseless and often the posterior pharyngeal wall may be seen.

Though ablation of cartilaginous deflections usually takes but little time, is often surprisingly simple and hardly hurts at all, removal of bony deviations requires more patience and causes moderate pain. The Roe forceps used in my earlier work often caused much suffering, and there was uncertainty as to what it would accomplish. In the not rare cases where the quadrangular cartilage is unusually large and extends far back, and

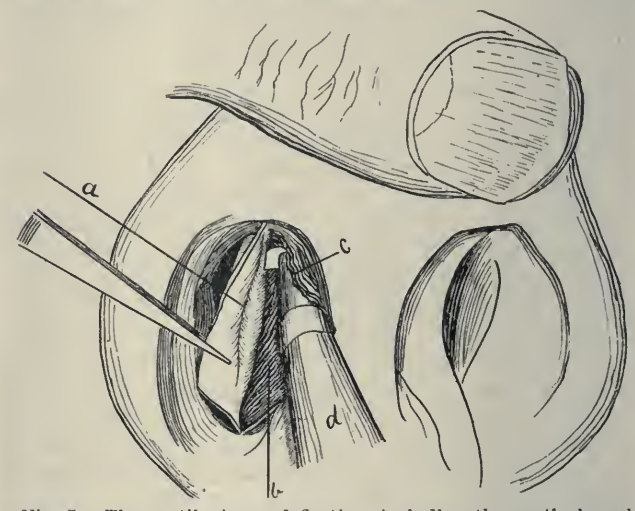

Fig. 5.—The cartilaginous deflection, including the vertical angle a, has been cut through at its base and in front and is being severed behind and above by the angular cartilage knives; b, inner surface of the mucosa of the concavity of the deflection; c, anterior flap folded out of the way; d, angular cartilage knife.

hence the septum is very elastic, the forceps often failed to fracture it, or it misplaced fragments and produced unwelcome prominences. Therefore, as I grew bolder in operating I discarded fracturing for the more precise method of cutting away the bone. I found that as long as I did not strain the septum by forcing it over I caused but little more pain when I cut the bone than when I cut cartilage. When

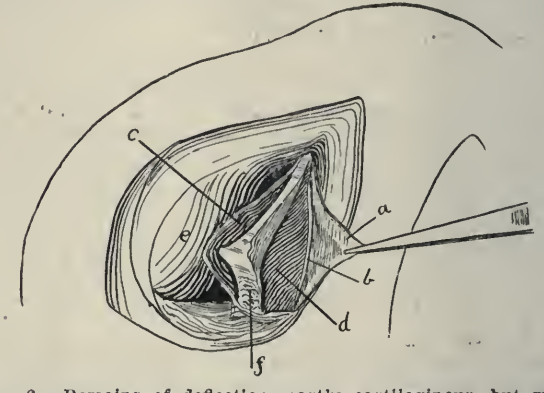

Fig. 6.—Remains of deflection, partly cartilaginous, but mainly bony, left after removal of major part of cartilaginous deflection. a, Anterior flap; b, anterior cut edge of cartilage; c, separated mucosa of convexity of deflection; d, inner surface of mucosa of concavity of deflection; e, inferior turbinal; f, bony base of deflection.

the bone is not too heavy it may be cut away piece by piece with the large Gruenwald forceps which follow it up between the two layers of the mucous membrane. Where the bone is too thick to cut through at the first bite it may be seized repeatedly with it until enough weakened in some place to punch through, or it may be prepared for cutting with forceps by short cuts into its substance with the chisel. After the

first piece is out the others cut through more easily. If the bone remaining at the base of the septum be too thick to cut away with the forceps or the gouge without forcible malleting the trephine should be used, driven by a strong, high-speed dental engine. In order to make sure that the trephine will bore into the bone without slipping at the start I use the Stacke gouge to start a chip and slip the trephine onto this as a guide. Once a core is cut out with the trephine the punch forceps usually readily trim off the rest of the bony deviation. If not, a second core may be cut out. I have employed the trephine in 17, or about one-third of the total number of my cases. Since I have obtained the later Gruenwald forceps with strong, large blades I have needed the trephine less, and this is an advantage, as the trephine causes more pain.

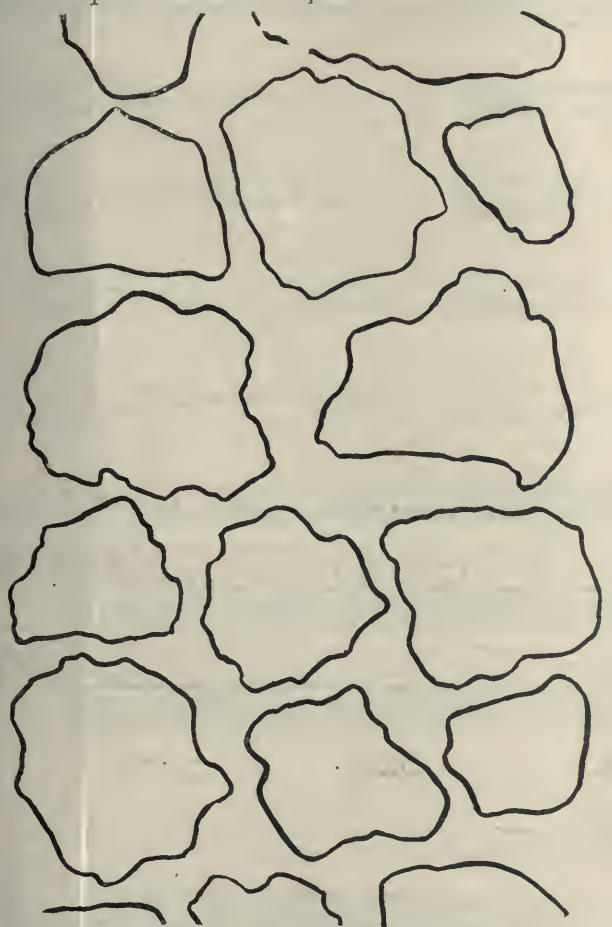

Fig. 7.—Outlines showing the amount of cartilage or cartilage and bone removed in a number of operations. (Actual size.)

In several of my cases the bony deviation extended back to near the posterior border of the vomer and so high up that it blocked the rear portion of the middle meatus, which must be cleared to give the patient the feeling of free respiration. The bony resection is not complete until the patient can breathe without stenotic sound through the operated naris when the flaps have been replaced. One can not always avoid tearing the posterior flap on the convex side when the deflection extends far back, but all torn portions should be preserved.

Oozing of blood is usually greater in the bony part of the operation so that frequent swabbing causes delay.

Perforations do no permanent injury to the patient, but retard healing, as secretions lodge in them until the wounds are well. The nasal saw is not as well fitted for the bony part of the operation as the punch forceps or trephine. Its use causes more pain, tears the flaps and removes the bone too superficially.

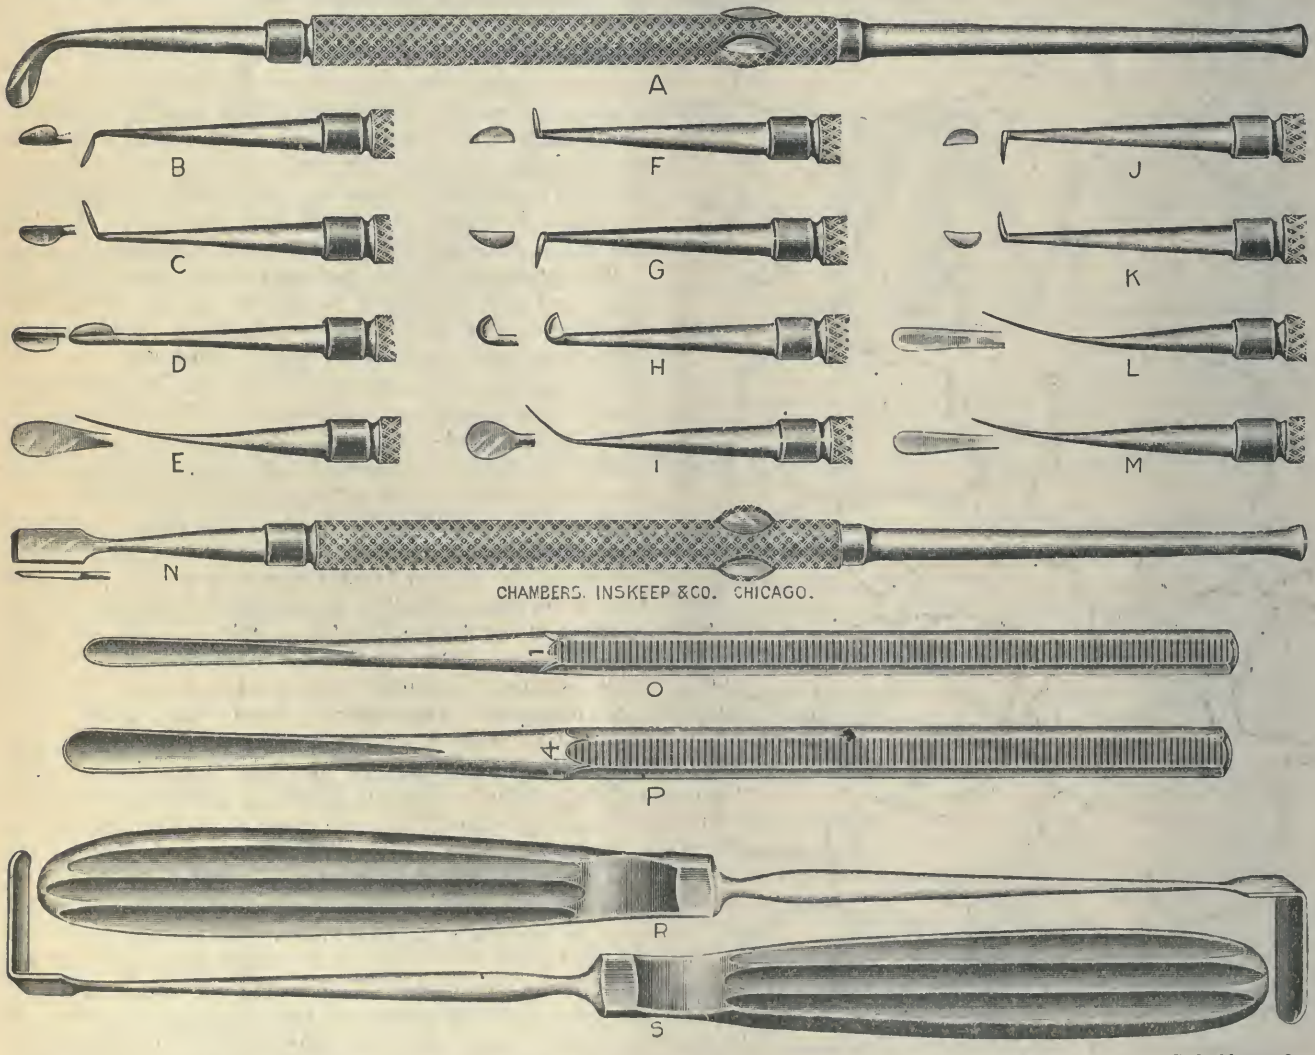
Bony deviations beginning far back are mistaken for exostoses by many operators who saw off the most projecting part with its covering of mucous membrane so that the piece removed frequently consists largely of the latter containing a thin crest of bone which is merely the apex of a deflection, as the saw often springs away from the septum and does not enter it deeply enough to cut away more. Prominences thus sawed off reform in great part when recovered with mucosa, as not enough bone is removed. In one of my cases the top of a deflection had been sawed away by another surgeon as an exostosis and the obstruction was completely reproduced. The resection operation gave radical relief. Crests and spurs nearly always, in my experience, rest on deflections of varying degree. Where the deflection is slight I think a better method than sawing off the crest or spur is to denude it and to gouge it out deeply, in the cartilaginous portion with the gouge and in the bony part with the trephine or burr. This will prevent its reforming. Where the deflection is of any consequence, however, it is better to exsect both deflection and crest from the bottom as described, in order to avoid imperfect results.

Deflections beginning far back are partly or entirely bony and may be entered by means of a vertical slit in the cartilage in front of them, followed by separation of mucosa and resection, as other deflections.

The amount of cartilage and bone cut out in a number of my operations is shown in outline (Fig. 7), and proves how little ordinarily need be excised to give relief, but no harm is done where much is removed, as the tissue ablated is of no physiologic importance.

When the operation is finished the flaps of mucous membrane are smoothed down with a damp cotton swab and the nostril is packed with a strip of lint one-fourth to five-eighths of an inch wide, rubbed full of subnitrate of bismuth. The packing must be done evenly and gently from the bottom with forceps with smooth, slender blades. I do not use the metal guard mentioned in my first paper, but steady the flaps with rat-toothed forceps while packing. One of the perforations was caused by too tight packing with a strip too broad so that it bunched unevenly and forced its way through the intact mucous membrane. The secondary hemorrhage in one of the two cases resulted from too loose packing. Beyond these two cases the tampons have caused no trouble. It is not safe to dismiss a patient unless the operated nostril be evenly filled with lint, as bleeding may occur within an hour or two when the effect of the cocain and adrenalin is gone. Sloughing of flaps I have never seen. In extensive resections it is sometimes well to support the bulging mucosa by a tampon in the other nostril. Bismuth tampons do not become putrid. As much of the strip as pulls out easily may be cut off daily until in about three to five days all of the packing is removed. If any of it catches on rough bone on the nasal floor it may be loosened by twisting the lint strip into a revolving rope.

The reaction and pain after the operation are so slight that patients do not need to go to bed, but should not work for from three days to a week. Fever with suppuration of the wound surfaces occurred in three cases. Both conditions subsided in a few days. In one of these patients a deflection of the perpendicular plate of the ethmoid bone, which caused distressing reflex symptoms by pressing into the right middle meatus in front, was



removed with permanent relief. No other complications than those mentioned occurred in my cases.

For after-treatment I have the patient spray his nose with normal salt solution and swab the nasal vestibule with an ointment of lanolin and vaselin to prevent crusting. For a week to six weeks after the operation the naris operated on is more or less obstructed by swelling, therefore the patient should be warned that for some time he will not breathe as well through the nose as he did when the operation was finished, but he may be assured of a perfect result, for in no case has the full capacity of the nostril failed to return when it was perfectly cleared at the time of the operation.

When bone needs removal the operation is sometimes long, from an hour to two hours, but the patient suffers mainly the discomfort of tedious sitting while the surgeon's loss of time is made up by the simplicity of the after-treatment.

The lumen of the opposite naris remains unchanged. It is not narrowed by crowding of redundant portions of the septum into the other naris as in fracturing methods.

The results in all of my cases but two were perfect, the obstructed nostril becoming completely clear. The two cases mentioned were among my first, and in one, through inexperience, I did not remove the obstructing bone completely. The second patient was a girl of 14 who had a bowed deviation of the entire septum of extreme degree. The operation entirely cleared the naris, but in the course of a year, as the septum grew in size with the girl's growth, the obstruction was partly reproduced. Such of my other patients as I examined long after the operation had even more patency than some weeks after it. I have not found proof of the reproduction of the removed hyaline cartilage, but the septum at the site of the resection becomes firm in some cases, while in others the window is filled with a tough strong partition.

Ffg. 8.—A, round-bladed knife, bent on edge, for dissection of mucous membrane from bony base of deflection; B and C, half-round-bladed angular knives for vertical incision in mucous membrane and first cut in cartilage, when deflection is far back in the naris; D, half-round-bladed straight knife for vertical incision in mucous membrane and first cut in cartilage when the deflection is nearer the front; E, flat, round-bladed dissecting knife; I, angular round-bladed dissecting knife; F, G, J and K, sharp-pointed, angular cartilage knives for cutting through back and upper part of cartilaginous deflection; H, Ingals' submucous cartilage knife; M, dull-edged dental spatula for uplifting of mucosa; L, sharp-edged dental spatula for dissecting up mucosa in concavity; N, Chisel: O and P, gouges; R and S, retractors for holding nostril open.

In one of my last cases I used a small guarded dental circular saw, driven by the dental engine. It makes vertical cuts through the bone where it is not over one-sixteenth of an inch thick, with great ease, and these cuts may be joined by horizontal ones from in front with the punch forceps to remove a piece of some size.

Fuller experience with the resection operation for septal deflections has given me confidence that there is no variety of deviation of the septum it can not remove in a neat and surgical manner without injury to the

patient. Even anteroposterior sigmoid deflections, blocking both nares, may be dissected out from the same nostril in one operation, including both bends. Dr. Charles H. Knight says that "such a sweeping operation as the window resection is only justified in extreme cases," giving the impression that the procedure is formidable. None of the operators has found it so. It is not "trying for the patient," and the after-effects are slight.

E. F. Ingals, in 1882, established the method of partial resection of septal deflections. In 1886, Krieg removed the entire deflection by his window resection. Without knowledge of Krieg's or Boenninghaus' later article, I developed my method of total exsection of deflections, so that my instrumentarium and technic are original and I have improved them as my work progressed. According to the needs shown by my operations I shaped the blades of the knives, which I made myself, and my present instruments are far better adapted to the work than the cruder ones described in my first paper. I can assure those who have found the operation tedious and difficult that by the use of the exact counterpart of the instruments (Fig. 8) which I use now, especially the knives, the operation may be done in a reasonable and often a short time and with a precision and ease much in advance of what was possible for a reader following my first paper. I hope that others will still further perfect the technic of this operation, which is so certain in its results and inflicts such slight injury on the patient.

288 E. Huron Street.

DISCUSSION.

Dr. O. Joachim, New Orleans—The essayist has undoubtedly operated on cases that had been unsuccessfully operated on by other physicians. I wish to know how he handles such cases, particularly those of cartilaginous deviations which have been unsuccessfully treated and in which cicatricial covering of the cartilage has taken place. How does he handle the cicatricial tissue?

Dr. O. T. Freer—As to those cases in which the mucous membrane is bound down by cicatricial tissue after the Asch operation, two Asch operations and one exostosis have given me opportunity to try the treatment of those cases. In two of the cases I avoided perforation in spite of the fact that there had been cicatrices. In one case there was an unavoidable perforation.

Dr. J. F. Barnhill, Indianapolis—We find the nasal septum deformed in so many ways that it seems to me probable that no one operation could ever prove sufficient for all, and I presume Dr. Freer does not claim that his method would be satisfactory in all cases.

Dr. O. T. Freer—I believe this operation is suitable for all cases.

Dr. J. F. Barnhill—I have seen cases in which only a very short time was necessary to set the septum into a new and better position by following the Gleason method, and I should not like to discard this method in such cases, because of its certainty of cure and ease of manipulation. After its performance the reaction is practically absent, and the pain is so slight that it seems almost an ideal operation. The array of instruments shown by Dr. Freer seems rather formidable, and would lead one to the belief that the operation is very complicated. Are most of these instruments required in doing the operation after the method described?

Dr. Sargent F. Snow, Syracuse, N. Y.—I arise to commend, perhaps, not the special method, but the proposition to resect portions of the septum in certain cases. I am not ready to use the Doctor's method exactly, for I have a method of my own that necessitates dissecting up the membrane only on one side, but it is perfectly practical to resect portions of the septum in selected cases, and Dr. Freer has opened up an important line of thought.

Dr. George E. Shambaugh, Chicago—I saw one of Dr. Freer's cases one month and another one week after the operation, and both were entirely successful.

Dr. B. R. Shurly, Detroit—Is Dr. Freer familiar with the work of Dr. Menzel of Vienna? His technic is largely the same, only it has the additional advantage of suturing the flap after the incisions. The flap is held back by a suture passed over the ear. The operation is completed by sewing down the flap dissected on the lower border.

Dr. Henry Gradle, Chicago—I would like to confirm Dr. Freer's statements. My own experience in this operation has not been as large as Dr. Freer's because nasal work is only a part of my work. However, my own limited experience confirms the good ultimate results of which he speaks. The operation, however, is not an easy one. It is difficult to save the reflected mucous membrane on either side. After one has done the operation a few times it becomes easier.

Dr. J. F. Hill, Memphis—I have had a number of cases in which there was a bony enlargement; it is very difficult to get rid of them, and the suggestions of the essayist seem very practicable. As to the cartilaginous portion of the septum, I don't want anything better than the Asch operation. The breaking up of the septum I do not think is practicable.

Dr. Otto T. Freer—Dr. Barnhill considers my instruments numerous. The reason for this is that many of them are little knives whose blades have varying shapes and attachments to their shanks to enable them to move in the proper directions on the field of operation, which all must reach by the same narrow passage—the nostril. There are 12 of these little knives; 3 forms are represented twice, as rights and lefts for each nostril. Their simple form and cheapness make up for their number. As in Dr. Myles' ethmoid work, a number of instruments is needed with slight change in shape, and I think this is true of many exact operations in narrow places. The Gleason and Asch operations possess the fault in common that they depend on fracturing to complete the work. This means more violence to the patient than by cutting methods, and uncertainty as to the result. The fracturing, if in bone, may create fissures that take dangerous directions. A double sphenoidal suppuration that I have seen follow an Asch operation seemed to me due to a fissuring fracture. Gleason himself advises fracture of the neck of his flap high up, if possible in the bone. From his description he must mean the perpendicular plate of the ethmoid bone, which I think it dangerous to break, considering its connection with the cribriform plate. A number of operators has spoken to me about the tendency to recurrence of the deviation after the fracturing operations. None seemed to feel sure of the perfection of the ultimate result. Fetterolf, in commenting on the Asch and Gleason operations, mentions the tendency to recurrence of the deformity in spite of tubes and pressure, though at the time of operation the result seemed ideal. I have never found suturing necessary, and it would needlessly prolong the operation. In operations on the extreme anterior end of the septum I have used a stitch or two, but they may be dispensed with even here. The credit for first establishing the principles of the complete window resection operation is undoubtedly Krieg's, and prior to his work Ingals describes the first partial resection of the cartilage. Doubtless Dr. Shurly has seen Menzel operate according to the description of the operation by Krieg and Boenninghaus. My methods of performance, especially the rapid exsection of the whole cartilaginous deviation by properly made knives instead of forceps or scissors, are original. The instruments I now use for separation of the mucosa of the concavity from its attachment, the round flat-bladed knives and the long sharp and blunt spatulæ, have shortened the cartilaginous part of the work very much. I do not expect the resection operation to supplant that of Asch. The latter will always be resorted to by the general surgeon who enters special fields without special skill, for the surgeon sins against us far more than the cautious general practitioner, anxious for his patient's welfare. Made bold by successful work in major operations, and a sense of superiority due to the cus-

tom which exalts surgery above the other branches of medicine, the busy general operator is apt to enter fields that belong to the specialties and to do some rather rough work there. While the resection operation will not displace easier methods, I think it should be the operation for the rhinologist, whose neat, exact surgery in the nose should distinguish him from those lacking his special skill.

GENERAL SURGICAL ANESTHESIA.*

ERNEST J. MELLISH, M.D.
Surgeon to Hôtel Dieu (Sisters' Hospital).
EL PASO, TEXAS.

In the light of our present knowledge of practical anesthesia, it is not justifiable to employ any one anesthetic exclusively. The safest anesthesia depends on (1) the choice of the anesthetic best adapted to the individual case; (2) the technic of preparation for and administration of the anesthetic, and (3) a skilful anesthetizer. In a considerable proportion of operative cases the life of the patient depends on the proper choice of the anesthetic and the management of the anesthesia. The recent advances in our knowledge of local and neuroregional anesthesia have materially narrowed the field of general anesthesia.

Almost every kind of operation has been attempted, and more or less successfully performed, under local or neuroregional anesthesia. However, the mere fact that an operation can be performed under local or regional anesthesia is not sufficient justification to do it. The shock to some individuals from even trivial operations under local anesthesia is greater than that produced by a properly selected and administered general anesthetic. This is particularly true in some cases of heart disease, as well as in neurotics. It has been found also that postoperative complications occur fully as often after local as after general anesthesia. That, as a rule, a surgeon can do better work under general than under local anesthesia, there can be no question. Nor can there be much doubt that many of the postoperative complications (septic embolism, etc.) after local anesthesia are due to incomplete operating—unfinished work. In children the local method usually is inapplicable. Lastly, the time of the surgeon and the tax on his vitality deserve some consideration. It is not justifiable for a surgeon to fritter away his time on one or two operations under local anesthesia when he might be doing five or six under general anesthesia, with little or no more danger to the patients.

The general anesthetics which deserve special consideration are: ether, chloroform, nitrous oxid, ethyl chlorid, ethyl bromid and pental.

ETHER.

Physiologic Action.—Ether is primarily a diffusible stimulant, like alcohol in its effects. These effects are more quickly produced and more transitory than those of alcohol. It increases arterial tension and acts as a cardiac stimulant, the heart continuing to beat after failure of respiration, as a rule. On the nervous system it acts as a paralyzant, affecting, first, the cerebrum; next the cerebellum; then the sensory, and later the motor functions of the spinal cord; then the sensory centers in the medulla oblongata; and, finally, the motor centers in the medulla.

Ether is eliminated chiefly by the lungs and kidneys unchanged, and, to some extent, by the liver and skin.

Postanesthetic Effects.—By this term is meant the conditions which become manifest from the time of awakening from the anesthesia until recovery or death.

Blood.—The hemoglobin percentage is practically always lowered by ether, which means that the oxygen-carrying capacity of the erythrocytes is reduced. John Chalmers Da Costa and Frederick J. Kalteyer[1] studied the blood changes induced by the administration of ether in fifty cases. The average count of erythrocytes before operation was 143,360 less per cubic millimeter than after operation. This was undoubtedly due mostly to the blood concentration caused by preparatory treatment (hot bath, active purgation, withholding all food and liquid for some hours preceding operation) and to sweating during anesthesia. The hemoglobin percentage was apparently increased in nineteen cases—the average gain being 8.05 per cent.—and decreased in twenty-eight cases—an average of 7.25 per cent. The average hemoglobin percentage in all the cases preceding anesthesia was 89; the average percentage following anesthesia was 86, showing an average loss of 3 per cent. The color index was reduced an average of over 8 per cent. The average gain in the number of leucocytes per cubic millimeter after anesthesia was 4,586. It is altogether probable that the apparent gain in hemoglobin in nineteen of the cases was due to the blood concentration, and that the whole amount of hemoglobin was reduced in every case.

Kidneys.—There is a difference of opinion as to the effect of ether on the kidneys, but the consensus is that, while it causes more or less irritation during the administration, this effect is of short duration in the kidney not seriously diseased.

By the administration of methylene-blue, it has been demonstrated that ether diminishes the permeability of the kidneys, and it is quite probable that toxic substances are eliminated less rapidly after ether narcosis than occurs with kidneys unaffected by ether.

Clinical experience along this line is conflicting. In a former article[2] I noted that albumin was found in 6 per cent. of 1,500 cases after ether narcosis, where none had been present before. Casts, hyaline, granular and epithelial, were found in a large proportion of the cases, unaccompanied by albumin. The casts and albumin disappeared rapidly. Wunderlich found that albuminuria and casts may be caused by ether, and that both when present before are increased by ether. According to Carl Beck of New York, out of 300 non-albuminuric ether cases 9 per cent. subsequently had distinct albuminuria. Trieber and Roux examined several hundred cases and failed to find albuminuria in any. Körte found albuminuria in 1 per cent. of 600 cases, and Butler once in 500 cases. Robert F. Weir[3] believes that ether has no marked effect upon healthy kidneys, that it is safe in slight kidney disease, and that circulatory disturbance which may arise in the kidneys quickly subsides. Leppman,[4] after an experimental research, confirms the conclusions of Lengemann and others that ether has no special degenerative action on the healthy kidneys. At any rate, such changes occur very seldom and only to a slight degree. The same may be said regarding the liver. I have records of 100 cases where the urine was tested before and after etherization. In one of these a trace of albumin was found after anesthesia where

there was none before. In no case out of several hundred ether anesthesias was there any noticeable post-anesthetic renal trouble. In my judgment, practically all of the especially unpleasant effects of ether on the kidneys have been due to careless selection of cases or bad technic. Cases of anuria have followed ether narcosis in persons suffering from chronic nephritis. In such cases general anesthesia is contraindicated. In advanced nephritis local anesthesia should be employed in preference to general, but if a general anesthetic must be given, nitrous oxid or ether are probably the safest of any. Much depends on the management of the case before, during and after the anesthesia.

Respiratory Tract.—Ether is distinctly irritating to the membrane of this tract and markedly increases the secretion of mucus, the degree of irritation depending much on the technic of administration.

Lung edema is present during the administration of ether and for several hours after, and it increases the possibility of hypostatic and aspiration pneumonias. The danger of aspiration pneumonia is greater where there are suppurative lesions in the mouth and pharynx.

The cases of lung complication following local anesthesia demonstrate that the nature and extent of the operation, especially celiotomies and operations on the mouth, neck and thoracic cavity, contribute to the production of these complications.

Cardiovascular System.—Ether causes a temporary rise in the carotid blood-pressure, followed by a moderate and gradual fall. The capillaries are dilated; the vascular tension increased. It produces no marked degenerative changes in the heart.

CHLOROFORM.

Physiologic Action.—After a brief period of stimulation it acts as a sedative and, in overdose, as a cardiac poison. It was demonstrated by Prof. John A. MacWilliam of Aberdeen that, even when slowly inhaled in moderate quantities and with a good admixture of air, chloroform causes an appreciable dilation of the heart.

Chloroform is eliminated chiefly in the form of chlorids by the kidneys; about a third is excreted as chloroform by the lungs and kidneys. It may also be found in the milk of nursing women and in the fetal blood. Owing to its destructive action on the erythrocytes it produces hemoglobinuria and bilirubinuria. As demonstrated by K. Buedinger,[5] chloroform elimination continues for several days after administration. He found it in the sputa as much as 5 days after administration. Much mucous secretion means slow elimination, the chloroform evidently combining with the mucus.

POSTANESTHETIC EFFECTS.

Blood.—There is little room for doubt that chloroform combines with the erythrocytes, causing death of a considerable proportion of them, and marked lessening of the hemoglobin—the oxygen-carrying element. In 1890, Mikulicz noted that the administration of chloroform may reduce the hemoglobin from 5 to 10 per cent. In 1893, Garrett and Oliver concluded, as a result of experiments, that anesthetics, particularly chloroform, deoxidize the blood and the tissues, thus producing malnutrition and the formation of quantities of waste products, the elimination of which causes a severe, and possibly a fatal, strain upon the excretory glands.

5. Wien. Klin. Woch., Aug. 1, 1901 (quoted in THE JOURNAL Am. Med. Assn., vol. xxxvii, p. 608).

Kidneys and Liver.—Experiments on healthy animals and autopsies on man prove that chloroform produces fatty degeneration of the kidneys and liver. The experiments of Thompson and Kemp apparently indicate that the immediate effects on healthy kidneys are slight, as albuminuria when present during narcosis was slight, and the secretion of urine continued up to the last moment of life. Fränkel called attention to the fact that chloroform sometimes gives rise to fatty changes in the kidneys and liver from which death may result. Wunderlich found, from investigation in 125 cases, that albumin when present was not increased by chloroform, but that albuminuria and casts were not seldom caused by it; that chloroform nephritis occurs. In 70 cases of chloroform anesthesia reported by Patein, 12 per cent. showed albuminuria before, 15 per cent. during, and 73 per cent. after anesthesia. As a rule the albumin disappeared within 48 hours, and the length of the anesthesia seemed to bear no relation to the albuminuria. D. N. Eisendrath[6] reported that albuminuria was present in 15 per cent. of 650 cases after chloroform anesthesia where there was none before, and in 6 per cent. of 1500 cases after ether where none had been present before. Casts were found unaccompanied by albumin more frequently after ether. In over half of the cases there were casts where no albumin was found. Casts and albumin disappeared rapidly, more so after ether than after chloroform. L. Wechsberg of Vienna[7] tested the urine in 100 cases of chloroform anesthesia, finding biliary pigments in 16, and in most of these there was icterus, probably indicating some abnormal condition of the liver.

Respiratory System.—The first effect produced by chloroform is reflex irritation of the vagus through the terminals of the fifth nerve in the nose. The after-effects on the lungs and bronchi are similar to those of ether, only less pronounced. A large proportion of the chloroform taken into the system is eliminated by the pulmonary mucous membrane, and, being heavy, it is eliminated slowly. Besides its direct irritating effect during inhalation and elimination, it undoubtedly lowers the physiologic resistance and leads indirectly to the occurrence of bronchitis and pneumonia.

Cardiovascular System.—Fränkel[8] proved beyond a doubt that fatty degeneration and fragmentation of the heart muscle, both in man and animals, follow the administration of chloroform as an anesthetic. Previous to Fränkel's publication, several observers had noted similar changes in animals after chloroform inhalation. Since then, Ambrosius, Mathen, Bastianelli, Heinz and others have reported cases of the kind in man. Lengemann,[9] experimenting on dogs with definite amounts of chloroform, found that the amount of chloroform given made very little difference in the extent of the fatty degeneration of the different organs. While a certain amount of chloroform must be in circulation before fatty degeneration can be produced, he found that this quantity was always present when sufficient chloroform had been given to produce narcosis. Repeated narcoses increased the extent of the degeneration. A large proportion of the cases where fatty degeneration of the heart was found in man occurred after anesthesias, prolonged for 2 or 3 hours, and this accords with *a priori* reasoning.

NITROUS OXID.

Physiologic Action.—Formerly it was thought that nitrous oxid was merely an asphyxiant, that its anesthetic properties were due entirely to its exclusion of oxygen. It is, however, a true anesthetic, and may be given with an admixture of air or oxygen with the result of producing quiet anesthesia without asphyxial phenomena.

Nitrous oxid is non-irritant, or nearly so, to the respiratory mucous membrane. It causes a positive and rapid rise in the blood-pressure, while there is slowing of cardiac action. Soon the heart beats faster and there is a fall in arterial pressure, due to vasomotor paresis. The respiration is labored and may be arrested by obstructive stertor or spasm of the respiratory muscles. When given without admixture of oxygen it produces asphyxia, manifested by stertorous respiration, cyanosis and dilation of the pupils—and in these cases the anesthetic effects are due largely to the asphyxia. In deep narcosis from nitrous oxid the renal vessels are contracted, the secretion of urine is diminished, and albumin may be found. The gas is eliminated unchanged by the kidneys and lungs.

The after-effects of nitrous oxid are, as a rule, transient; limited to slight dizziness, nausea or headache, lasting a few hours. Occasionally there may be albuminuria or dilation of the heart, the latter continuing for several days.

Nitrous oxid has until recently been employed for short anesthesias only, chiefly for tooth extraction. In 1899 Frederick W. Hewitt[10] published his deductions from observation of 231 cases of nitrous oxid narcosis. Pure nitrous oxid was given in 22 cases; nitrous oxid mixed with different percentages of air, 107 cases; nitrous oxid mixed with different percentages of oxygen, 102 cases. He concludes that when pure nitrous oxid is given the most conspicuous of the anesthetic phenomena are embarrassed and deeply stertorous breathing, cyanosis, and anoxemic convulsion. Other less obvious asphyxial phenomena are dilation of the pupils, swelling of the tongue and adjacent structures, and rapid cardiac action. All these may be eliminated or greatly modified without interfering with the anesthetic effects of the gas by administering it with certain proportions of oxygen, either pure or atmospheric. If the administration be pushed far enough, breathing is arrested by obstructive stertor, by anoxemic convulsion attacking the respiratory muscles, or by both combined. Paralytic cessation of breathing is very rare, and when it occurs is dependent quite as much on cerebral anemia from defective circulation as on the presence of unoxygenated blood in the vessels supplying the respiratory center. The deep and obstructive stertor of pure nitrous oxid narcosis is not met with when employing mixtures containing moderate percentages of air or oxygen, and when the percentage of oxygen is considerable—30 per cent. air or 13 per cent. oxygen—respiration becomes noiseless and free from obstruction.

Nitrous oxid is by far the safest general anesthetic we have. According to H. C. Wood[11] there were but 4 recorded deaths up to 1900 which could be certainly attributed to the drug. Hewitt,[12] however, records 17 deaths positively due to nitrous oxid, and 6 others probably due to it. Obviously, it is not entirely without danger. It is probably within the bounds of fact to estimate the death rate as low as from 1 to 3 in 1,000,000 narcoses.

ETHYL BROMID.

Ethyl bromid is almost non-irritant to the respiratory mucous membrane—by some it is believed to be sedative to this membrane. H. C. Wood found that its action on the heart was about the same as that of chloroform, and death occurs usually from cardiac paralysis. During its administration the skin and lips should not change color, nor the pupils become dilated.

The after-effects are generally limited to slight vertigo, nausea or headache. There is a garlicky odor to the breath for from one to three days after administration.

It is not at all safe to give ethyl bromid for more than 2 or 3 minutes, as longer administration is very liable to cause circulatory and respiratory failure. It is administered in 4 to 12 gram doses without admixture of air.

ETHYL CHLORID.

My experience with ethyl chlorid as a general anesthetic is *nil,* but from the data at hand I am inclined to class it with the more dangerous anesthetics, and would expect it to be especially dangerous in cardiac and respiratory troubles. Benjamin W. Richardson has asserted that an anesthetic is dangerous in proportion to the chlorin it contains, and it may be that his belief was founded on sound principles. Almost every reporter on ethyl chlorid anesthesia mentions a death in the literature. Although several deaths have probably occurred, it is likely that repetitions have occurred in the reports. Lotheisen (1900) reports 1 death in 2,500 cases, while Ware (1902) says that but one death has been reported in over 13,000 cases. He places its safety between that of ether and that of nitrous oxid.[13]

PENTAL.

Administered by inhalation, 8 to 12 grams are usually sufficient to produce anesthesia. Loss of sensibility occurs within 50 to 90 seconds without entire abolition of consciousness, but the effect may be pushed to profound anesthesia. The pupils sometimes dilate widely. Return to consciousness is gradual. Pental has been used little or not at all in the United States, but in Europe it was tried quite extensively some years ago. It has been almost discarded as a practical anesthetic.

EFFECTS OF ANESTHETICS DURING NARCOSIS.

As to ether there is little difference of opinion, nearly all agreeing that in almost all cases its dangerous effects are manifested primarily by disturbances of the respiratory system.

In the case of chloroform the diversity of opinion is great. N. Senn agrees with the second Hyderabad Commission (superintended by Lauder Brunton), that chloroform kills by its effect on the respiratory system. My belief has always been that the bad effects of chloroform were, as a rule, exerted primarily on the circulatory system, and increasing experience and observation go to confirm that belief. The circulatory and respiratory systems are very greatly interdependent, consequently that which affects one will also affect the other. This fact partly accounts for many erroneous interpretations of anesthetic narcosis phenomena. The majority of reports of deaths from anesthetics show evidences of inaccurate observations. Many times this is excusable, because when accidents occur the prime consideration

13. American Medicine, vol. iii, p. 1043.

is for the life of the patient and no time can be spared for technical observations. However, the majority of accidents might be avoided by closer attention to details and early recognition of conditions present.

Chloroform Syncope.—Leonard Hill[14] shows that there are two forms of chloroform syncope—primary and secondary—both forms being due to circulatory depression. Practically all observers agree that chloroform causes lowering of blood-pressure at all stages of the anesthesia, excepting momentarily at the beginning. The tracings of the Hyderabad Commission show that blood-pressure falls greatly before respiration ceases, but the Commission claims this has nothing to do with the heart, and that failure of respiration is the primary cause of death. If this be true, artificial respiration should be successful always, for it is well known that if the respiratory center be excised an animal can be kept alive for hours by means of artificial respiration. Lessening of blood-pressure is attributable partly to vasomotor paralysis and partly to cardiac failure. In rapid administration of an anesthetic the circulatory organs are in danger, and in slow administration the respiratory. Ether produces a slow fall of the blood-pressure, and chloroform a rapid.

MIXTURES AND SEQUENCES OF ANESTHETICS.

Both of these have their advocates, and with good reason in selected cases, especially as regards the sequences. These seem to be gaining prestige, especially the preliminary administration of one of the quick-acting and less disagreeable anesthetics—nitrous oxid—and continuing the narcosis with ether. A large number of combinations of ether and chloroform; ether, chloroform and alcohol; ether and alcohol; chloroform and alcohol, etc., have been used and warmly advocated. Morphin given before or during anesthetic inhalation produces mixed anesthesia; as do chloral, chloretone, cocain and other drugs. The weight of opinion is against the use of mixed anesthetics for routine work.

Schleich's Mixtures.—Dr. Carl Ludwig Schleich of Berlin[15] recommends for general anesthesia a mixture consisting of:

℞. Ethyl chlorid .....½ part to 2 parts.
Chloroform .....4 parts.
Anesthetic ether ..... 12 parts.

He records that he has used this mixture in about 5,000 cases without any bad results.[16] Some years ago Schleich gave it as his belief that mixtures of anesthetics of different boiling points are safer than the different anesthetics alone, on the assumption that the absorption of an anesthetic as to quantity depends on its boiling point. The more volatile an anesthetic the slower will be its rate of absorption. Ether, which boils at about 36 C. (97 F.) will be absorbed less rapidly than chloroform, the boiling point of which is about 61 C. (142 F.). He believed that if an anesthetic could be produced with a boiling point the same as the normal temperature of the blood, the exact amount absorbed with each inspiration would be eliminated with each expiration. He thinks that by producing mixtures with maximum evaporation points at different degrees above the blood temperature, we can regulate at will the excess which the expiration would not remove, and thus the amount of anesthetic retained in the blood. In order to accomplish this he added petroleum ether or benzine (boiling point 60 to 65 C.) to ether and chloroform in different proportions. His mixtures for inhalation consisted of three solutions:

No. 1, Boiling Point 38 C. (for Brief Anesthesia).

℞.	Ether	℥vi	186
	Petroleum ether	℥ss	15 5
	Chloroform	℥iss	46 5

No. 2, Boiling Point 40 C. (for Medium Anesthesia).

℞.	Ether	℥v	155
	Chloroform	℥iss	46 5
	Petroleum ether	℥ss	15 5

No. 3, Boiling Point 42 C. (for Prolonged Anesthesia.)

℞.	Ether	℥2 2/3	83
	Petroleum ether	℥ss	15 5
	Chloroform	℥i	31

Schleich claimed for these solutions that the anesthetist might be guided, as to the effects of the anesthetic, by the respiration alone; that there was no excitement, no tendency to irritate the bronchial tubes; the pulse had good tension and was never increased, but might be decreased, in frequency; that consciousness was regained more quickly than from ether or chloroform narcosis; and if the solution with a boiling point at about blood temperature were used, only a few respirations were taken before the patient became conscious.

These solutions were received with considerable enthusiasm by a number of American surgeons, among them Henry J. Garrigues, H. Rodman, and Walter Lathrop, the latter using them in 700 cases. Schleich's claims were not sustained in any very important respect, and so far as I know the solutions are not used here. My own experience with them was limited to 15 consecutive anesthesias, in 1898, when I encountered a case which convinced me that the solutions were at least as dangerous as chloroform. I believe the ethyl chlorid mixture will not stand the test of time better than his old mixtures.

Schleich's reasoning, that if an anesthetic could be produced with a boiling point the same as the normal temperature of the blood, the exact amount absorbed with each inspiration would be eliminated with each expiration, is fallacious, because a certain amount of the anesthetic would be retained in the blood and eliminated in part through the kidneys; and, moreover, the temperature of the body tends always to become reduced during anesthesia. In other words, the temperature of the body is not a constant quantity during anesthesia.

I do not believe that any form of chloroform mixture can be made as safe for routine use as ether.

Willy Meyer[17] reports his experience with "anesthol," a new anesthetic which he and H. P. Weidig, Ph.D., of Newark, N. J., have evolved out of the Schleich mixtures. He bases his recommendation of the use of anesthol on his experience with it in "many hundreds of cases operated on during the last 4 years." In this series of cases there was one death on the table directly attributable to the effects of the anesthetic. In this case it appears that respiration and circulation ceased suddenly, as in some forms of chloroform syncope. Meyer states that in all of the surviving cases in which dangerous symptoms occurred, it was the respiration and not the circulation which was especially affected. The anesthesia under anesthol is said to be tranquil, the circulation excellent and, when carefully administered, the respiration easy—much the same as with the original Schleich mixtures.

In my judgment, the great objection to the use of anesthol is that it contains chloroform—and a large proportion of it. Whether the ethyl chlorid contained adds to its toxicity must be decided by further experi-

14. Brit. Med. Jour., April 17, 1897.

ence with ethyl chlorid as a general anesthetic. Theoretically, I would consider Schleich's ethyl-chlorid-chloroform-ether mixture, above mentioned, decidedly less dangerous than anesthol, owing to the vastly smaller amounts of chloroform and ethyl chlorid contained in the former. Schleich's statistics with his latest mixture show far better results than do Meyer's with anesthol. I do not expect either of these mixtures to attain and maintain the high regard of surgeons in general, nor do I believe that any form of chloroform mixture can be made as safe for administration in routine work as ether.

The administration of morphin before or during an anesthesia by ether or chloroform to produce a mixed anesthesia is sometimes a distinct advantage. Morphin given before chloroform is likely to prevent the dangerous nasolaryngeal reflex and the "stage of excitement." Atropin given before ether administration very materially reduces the excessive secretion of mucus produced by the ether and is a distinct advantage. A hypodermic injection of morphin and atropin, then, before ether or chloroform anesthesia is good practice. Atropin as a cardiac stimulant tends to counteract chloroform depression.

SUCCESSIONS OF ANESTHETICS.

By this term is meant the induction of anesthesia with one anesthetic and its continuance with another.

Ether-Chloroform.—This method of anesthesia is often employed in operations about the face and its cavities, where partial or "talking anesthesia" is desirable. Giving the ether first reduces the amount of chloroform required, and the narcosis is more readily maintained with chloroform than with ether.

Chloroform-Ether.—This method is a favorite with a large number of surgeons. Primary anesthesia is induced with chloroform, which saves time and is less disagreeable to the patient, and the narcosis continued with ether.

Nitrous Oxid-Ether.—This method has become popular in both the United States and Europe, especially in England. The advantages of the method are: 1, the time required to produce anesthesia is reduced to from 2 to 5 minutes; 2, the discomfort to the patient is reduced to the minimum; 3, the nausea and vomiting following etherization are reduced. About the only real disadvantage has been that, on account of the apparatus required, the method was practically limited to hospital practice. However, its mode of administration has been so simplified that the cumbrous inhaler can be dispensed with.[18] An ordinary paper and towel cone open at both ends may be used instead of the closed inhaler. This reduces the danger of asphyxiation and is cleanly and inexpensive. This method of producing anesthesia approaches the ideal when the open method of administration is employed and the ether given drop by drop. With this method there is less change in the conditions to which the body is normally subject than results from any other form of anesthesia.

Nitrous Oxid-Ether-Chloroform.—This method of anesthesia is advised by Frederick W. Hewitt.[19] He bases his recommendation on these grounds: The gas makes the anesthetization easier and pleasanter for the patient; the ether can be administered during the chief part of the operation, and gives the anesthetist little concern, whereas chloroform produces greater quiet and muscular relaxation, and during the administration there is also a comparative freedom from venous engorgement. The danger from chloroform is during the second stage—that of excitement—which is avoided by the employment of this method. The disagreeable after-effects of ether are also avoided. This method is highly commended in operations about the mouth, throat and nose.

Ethyl Bromid-Ether.—This method is being tried somewhat extensively. The chief advantage of the method over the nitrous oxid method is that no special apparatus is required. Four fluid grams (1 fluid dram) of ethyl bromid is poured into a folded piece of gauze held in the palm, over which the fingers are partially flexed, forming a cone, and this is applied closely over the patient's nose and mouth so as to exclude air. Unconsciousness occurs on an average in 40 to 60 seconds. Ether is then substituted, and there is usually little disturbance when the change is made. In from 2 to 4 minutes more the anesthesia will be complete. Less ether is required than in pure ether narcosis, by the amount necessary to produce unconsciousness.

I have tried ethyl bromid-ether anesthesia in a few cases, with results about like the above mentioned. I am, however, unable to convince myself that ethyl bromid is not much more dangerous than nitrous oxid, consequently do not expect to employ the method again unless many thousands of administrations by others shall have demonstrated beyond reasonable doubt that it is as safe as nitrous oxid. There is not sufficient advantage in the ethyl bromid-chloroform method to warrant its employment.

Chloroform-Oxygen.—This method is probably safer than the ordinary chloroform method, but it is difficult to believe it is as safe as Heinz Wohlgemuth[20] implies when he says that he thinks overdose with this method is impossible. He reports 300 narcoses by the method. He uses an elaborate apparatus—in itself an objectionable feature.

CHLOROFORM AND AMYL NITRITE.

During the Civil War this mixture was used very extensively. Four grams (1 dram) of amyl nitrite is added to 1 pound of chloroform. The object is to reduce the danger of chloroform narcosis. The amyl nitrite perceptibly diminishes the cardiac depression of chloroform and improves the capillary circulation, as shown by less pallor. Cyanosis is less frequent than when pure chloroform is used. After observing its use by another surgeon (N. Senn) in a large number of cases I decided to try it. Its use in a few cases convinced me that the mixture is very much less safe than ether, though probably safer than chloroform alone.

PARTIAL OR TALKING ANESTHESIA.

This method is employed in bloody operations about the nose and mouth, instead of complete narcosis and Rose's (head down) position, to prevent blood from entering the trachea. A half hour before beginning the administration the patient is given 2 ounces of whisky or brandy in water, or 15 minutes before, a full dose of morphin hypodermically. The patient is placed with the head and shoulders somewhat elevated and the anesthesia carried only far enough to blunt or abolish the pain-sense, but the patient should remain sufficiently conscious to respond to questions and co-operate with the surgeon in clearing the mouth and throat of blood. This method does away with the necessity for preliminary tracheotomy in certain operations above the larynx.

Primary anesthesia may be advantageously employed for short operations—like the removal of adenoids,

18. Albert H. Miller: Annals of Surgery, 1899, vol. xxx, p. 709.
19. Gould's American Year Book of Med. and Surg., 1902, p. 48.
20. Interstate Med. Jour., St. Louis, October, 1901.

breaking up of ankyloses, thoracotomy, etc. Ether, and not chloroform, should be used, since in chloroform narcosis the time of greatest danger is during the moment when relaxation is occurring, just previous to the beginning of surgical anesthesia.

Nitrous oxid is the best anesthetic for short operations, but it should not (as is often done) be administered with the patient in the upright position, especially for operations about the pharynx, where blood or tissues are liable to be aspirated into the trachea.

ANESTHESIA IN HEART DISEASE.

As a rule, it is only in myocardial affections that anesthetics produce any markedly bad effects. In myocarditis ether is badly borne, and chloroform is dangerous in the extreme. In valvular disease, while there is appreciable disturbance, it generally is not great, and in functional affections the effects of anesthetics are insignificant.

In cardiac disturbances after anesthetics it is often difficult to determine whether the result is due to the anesthetic or to the operation. In some cardiac diseases ether has a temporarily beneficial effect, although the secondary effect may be unfavorable, the symptoms occurring after a lapse of days, perhaps. Ether is contraindicated in the presence of arteriosclerosis and high arterial tension. Nitroglycerin would tend to counteract this danger.

The effect of an anesthetic may, of course, show itself as a postanesthetic edema or pneumonia in these cases. No condition of the heart is an absolute contraindication to the use of an anesthetic, and ether is the anesthetic of choice.

TEMPERATURE CHANGES DURING ANESTHESIA.

All anesthetics tend to lower the body temperature, and the longer the narcosis the lower the temperature and the longer in recovering to normal. Depression of the nervous system and lowering of blood-pressure correspond closely to loss of heat. Ether causes profuse sweating, which, of course, lowers the temperature, the temperature also being lowered by evaporation of the ether. Atropin is useful in these cases as a vasomotor stimulant. The temperature may be lowered by anesthetics over 3 F. Loss of heat may be, to a great extent, prevented by properly covering the patient, by surrounding him with hot bottles, and by being careful to have the operating room at the right temperature (75 to 85 F.)

INHALERS.

There is a multitude of ether and chloroform inhalers on the market, some modeled for the "open method," others for the "closed method" of administration. The Esmarch chloroform mask and the Allis ether inhaler are types of the former, and the Clover and the Ormsby ether inhalers and the Junker chloroform inhaler of the latter.

The asphyxial element enters largely into the production of anesthesia when the "closed" kind of inhaler is used. I believe this adds to the danger. I discard this class of inhalers, as they are dangerous, cumbrous, expensive, and filthy. Take the Clover inhaler, for example. The patient's microbe-laden breath, to say nothing of its other constituents, is passed through the entire apparatus repeatedly, the face-piece is befouled with mouth secretions, stomach contents, etc., and this process is repeated time after time indefinitely. It is practically impossible to asepticize these inhalers, and even if this can be done, certain disagreeable odors can not be eliminated. Possibly, some of the pneumonias attributed to ether can be accounted for in this way. The Junker inhaler is so constructed that the inspired air is charged with chloroform vapor by being forced, by means of a hand-bulb, through the liquid chloroform, after which it reaches the face-piece through a rubber tube. The percentage of chloroform in the inspired air is regulated by the depth of chloroform through which the air passes. Some 12 years ago I employed this apparatus in a few cases—and it has ever since been an especial source of comfort to me that none of the patients died from its use. Only an expert can use the elaborately constructed appliances, and with some of them, like the Junker inhaler, two persons are necessary in order to conduct the anesthesia properly. The paper and towel cone, closed at one end, is open to the following objections: The supply of ether can not be properly regulated; the patient is apt to be asphyxiated into insensibility; the ether vapor is not sufficiently nor constantly diluted with air, and the method is wasteful.

The best type of inhaler, for ether and for chloroform, is one made on the principle of the Esmarch chloroform mask. Lawrence H. Prince of Palmyra, Wis.,[21] introduced this method in Chicago in 1895. It answers the purpose in most cases where ether can be used. The evaporating surface should be somewhat larger for ether than for chloroform, and the covering of gauze should consist of fully twice the number of thicknesses. In high altitudes and when the atmosphere is very warm, the mask should be modified, so as to allow its sides to be covered with a less pervious material—as in the mask devised by Nicholas Senn. Ernest Laplace has still further modified the Esmarch inhaler by covering the cone with metal, leaving ample opening at the top for air. All things considered, the Laplace inhaler is, perhaps, the best on the market. This kind of inhaler is cleanly, since fresh gauze is supplied for each case; it is efficient and safe, and the admixture of air can be easily regulated. I have modified the Laplace inhaler by having attached to the left side a ring for the thumb, which makes it easier to retain in place. The Esmarch or the Schimmelbusch masks can be made practically like the Laplace mask by covering the gauze with oiled silk or other impervious tissue, leaving an opening at the top.

TONGUE FORCEPS AND GAG.

A medium-sized double vulsellum will do less harm if properly used than the ordinary tongue forceps. The former simply makes two punctures, while the latter frequently lacerates and contuses the tongue. N. Senn has devised a tongue forceps, consisting of a lower, flat, fenestrated blade, with an upper, single tenaculum blade. I have modified this forceps by having a double tenaculum blade above and a heart-shaped blade below, instead of the pointed one. (Senn has recently changed his forceps to a double vulsellum.) I want to emphasize the fact that an expert anesthetizer seldom uses the tongue-holding forceps or the gag.

(To be continued.)

21. Chicago Medical Recorder, April, 1897.

Injection of Vaselin in Arthritis.—Delagénière of Mans recently treated a case of painful arthritis without effusion, involving the shoulder, by injecting vaselin. He hoped that it would act as a lubricant and keep the parts from painful contact. His hopes were realized as all pain vanished at once and there has been no recurrence during the three months since. Spontaneous physiologic movements of the joint were possible at once and all trouble from this source has ceased.

VAGINAL EXPLORATORY PUNCTURE AND CELIOTOMY;

THEIR ADVISABILITY IN DOUBTFUL DIAGNOSIS IN DISEASES OF THE FEMALE GENITAL ORGANS; REPORT OF CASES.*

C. O. THIENHAUS, M.D.
MILWAUKEE, WIS.

When some time ago in a discussion on the differential diagnosis of appendicitis, pyosalpinx, extra-uterine pregnancy, tuberculosis of the right tube and exudates in the right iliac region, I heard the opinion expressed by a teacher of gynecology: "What is the use of going into minute details of differential diagnosis in such cases? The abdomen has to be opened anyhow," I was unwillingly reminded of the general who without sufficient reconnoitering led his troops into an unknown valley, and afterward, encountering insurmountable difficulties, met terrific defeat. Though without question the advancements of modern surgery in the last twenty-five years have made an exploratory laparotomy a relatively safe procedure, so far as the immediate and probably the remote safety of the patient is concerned, yet it must not be forgotten that all therapeutic actions ought in every medical as well as surgical case to be based on a strict and correct diagnosis, and that all means and methods of diagnosis ought to be exhausted before reaching definite opinions and conclusions in regard to the therapeutic methods and routes to be employed in the individual case. "Not the idea of making large incisions to overcome difficulties in diagnosis, but the idea that when a surgeon makes a so-called explorative laparotomy he thereby confesses his ignorance, is real surgery and surgery of the future"—these words of Mikulicz[1] ought to be a *mene-tekel* in the operating room of those who, carried *furore operationis* on the diagnosis of a tumor in the abdomen, perform celiotomies regardless of the nature and operability of the disease in question.

In gynecology, bimanual, vagino-abdominal or recto-abdominal examination or a combination of both, enables us to make a diagnosis usually with more accuracy and more ease than in other regions of the abdominal cavity. But there are cases—and every gynecologist of larger experience has seen them—where the differential diagnosis between two or three diseases can only be made with approximative certainty or is even utterly impossible. In many of such cases, chiefly when the Douglas pouch is the seat of the disease, vaginal exploratory puncture, with or without vaginal posterior celiotomy, can not only affirm our up-to-this-point doubtful diagnosis, but at the same time further our decision, first, in regard to the operability of a case; second, concerning the advisableness of the vaginal or abdominal route as operative procedure.

I think nobody questions any more nowadays that vaginal incision and drainage in cases of abscesses of the pouch of Douglas, whether they originate from an infectious process in the uterus following abortion or birth or from a pyosalpinx or an appendicitis, is the method *par excellence;* nobody questions, furthermore, the advisability of the vaginal route for retro-uterine hematocele when infected either by way of the uterus or by way of adherent bowels. So long as we do not know whether the pus in an abdominal abscess is *pus bonun et laudabile;* so long as we are not in the possession of measures to determine the virulence of the bacteria and of the toxins present in the pus focus before operation, so long it must be our duty to open abdominal abscesses —where there exists a possibility—by an extraperitoneal route, that is, in women the Douglas abscesses by posterior vaginal celiotomy.

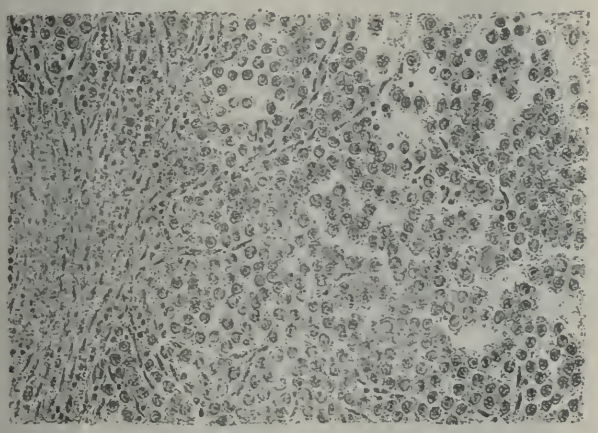
The diagnosis of such inflammatory exudate masses in the pelvis is, as already pointed out, not always easy. When they lie quiescent for a longer period of time they are often surrounded by a hard and thick shell of tissue, which not so seldom gives the impression of fibroid or, because of their irregularity, of malignant tumor. I observed two cases of retro-uterine exudate, in which the diagnosis of malignant tumor in one and fibroid in the other was made by other colleagues. Vaginal explorative puncture revealed a pus focus in the depth of six respectively of eight centimeters and the therapy; vaginal incision and drainage brought about a perfect cure within from six to eight weeks. It is the hardness and irregularity of such masses which can mislead to the diagnosis of malignant tumors.

That in cases where fluctuation is present in the posterior cul-de-sac, vaginal puncture may be of vital importance, I could demonstrate lately on three cases:

Mrs. R., 24 years of age, nullipara, states that she menstruated regularly and without discomfort since her fourteenth year. Fourteen days ago the menstrual flow was three days overdue and was connected with a sharp pain in her right side.

As the flow continued for more than nine days her physician was led to believe that an abortion had taken place and curetted the uterus. Very severe symptoms of peritonitis followed a few days after this procedure: pain in the lower region of the abdomen, elevation of temperature to 103 and pulse 140-150, together with frequent vomiting. When I was called into consultation to this—as the physician stated—absolutely hopeless case, I found the symptoms as above stated, the abdomen was tender all over, but chiefly in the lower portion. Bimanual examination revealed a fluctuating tumor of the size of a man's head in Douglas' pouch, pressing the somewhat softened uterus against the symphysis. As the woman showed no signs of anemia, I was inclined to the diagnosis of pelvic abscess following an abortion, though the irregularity in her menstrual period aroused my suspicion of possible extra-uterine pregnancy. Vaginal explorative puncture, followed immediately by vaginal incision, performed in the so-called exciting stage of ether anesthesia, revealed a large infected hematocele, resulting from a right-sided extra-uterine pregnancy. The patient made a perfect recovery.

Fever in case of ruptured extra-uterine pregnancy does not necessarily include that the hematoma or hematocele is already infected. It is a well-known fact that fever often follows severe hemorrhage, as for instance, hemorrhage from a puerperal uterus, without infection being present. This by the way.



In some cases the diagnosis between an unruptured extra-uterine gestation sac, chiefly when as far advanced as the third month of pregnancy, and pelvic abscess together with pyosalpinx, shows difficulties which can easily be overcome by vaginal explorative puncture.

The experience in a case five years ago, in which all the clinical symptoms, such as irregularity in the menstrual flow, absence of fever, etc., together with the findings by bimanual examination led three diagnosticians of reputation to the diagnosis of extra-uterine gestation of five months' duration, has taught me a lesson which I can never forget. After opening the abdomen in this case a pyosalpinx connected with an enormous abscess was found. In freeing a part of the adherent sigmoid

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. A. Palmer Dudley, H. P. Newman and J. H. Carstens.

1. Handbuch der practischen Chirurgie, by Von Bergmann, Brune and Mikulicz.

flexure, the abscess ruptured. General peritoneal infection followed the operation, to which the patient succumbed after forty-eight hours. Vaginal explorative puncture would have revealed the true nature of the disease and thereby indicated the vaginal route for operative procedure. Would vaginal incision and drainage have saved the life of the patient? It is my firm belief it would. Examples of this class have been very numerous, but are usually, unfortunately, not cited in literature. Many have been misled by the somewhat sweeping statement before the American Medical Association at St. Paul[2] that the vaginal operation for abscesses in Douglas' pouch was a dismal swamp procedure, and that vaginal opening was not a surgical operation. The free admission of Noble at Saratoga Springs one year later that through this error many a patient had lost her life which could have been saved by vaginal incision brought surgery back from the "bolder, more spectacular, but deadlier enucleation by the abdominal route," to use Reuben Peterson's words,[3] to the channels of logical sense and logical principles, that is, simple vaginal incision. The following case, in which a diagnosis without explorative celiotomy was absolutely impossible, shows that vaginal posterior celiotomy may in some cases

Round-cell sarcoma of the ovary. (Mrs. W.)

give evidence of the operability or inoperability of a tumor in question.

Mrs. W., 43 years of age, states that she gained in flesh in the last half year and that she felt perfectly well in every respect up to the last three months. At that time she felt a slight pain in the right iliac region, which she attributed to rheumatism. Four weeks ago the pain, accompanied by a slight rise of temperature, increased to such a degree that the family physician was called in. On examination he found three irregular hard tumors varying from the size of a goose egg to that of a small fist, originating from the uterus. Diagnosis: Subserous fibroids of the uterus. After examining her in consultation I confirmed this diagnosis, but suggested in regard to the rise of temperature, that an inflammatory condition, probably originating from the left tube and ovary and lying behind the uterus, complicated the condition.

Abdominal hysteromyomectomy was advised, to which the patient consented about eight days later. After transportation to the hospital, however, symptoms of peritoneal irritation with rise of pulse to 120 and temperature to 102 developed. An examination immediately before operation revealed that the entire situation had changed to a marked degree. The tumors attached to the uterus seemed enlarged considerably and could be outlined on the outer side of the abdomen. On bimanual examination a mass was found in the posterior cul-de-sac pressing down the rectum and bulging into the vagina. Apparent fluctuation was perceivable on one point of this mass. What was the cause of this change?

Three things had to be taken into consideration: First, a pus tube could have ruptured and produced a Douglas pouch abscess bulging into the vagina. This was the most probable explanation because of the rise of temperature. Second, rupture of a blood vessel in a tumor, or in a pregnant tube could have occurred, producing a hematocele. Third, a tumor mass could have broken down. As by explorative, vaginal puncture, no fluid of any kind could be aspirated, the third cause was the only one possible.

Vaginal explorative incision revealed a soft, friable tumor mass originating from the left ovary, which was enlarged to the size of a man's fist and broadly attached to the posterior wall of the uterus. The microscopic examination, as shown in the accompanying drawing, revealed a small round-cell sarcoma of the ovary. It was evident that the other tumors, which had grown so rapidly in the last five weeks and which were adherent everywhere to the surrounding organs, were of the same nature as the specimen examined. As hereby the inoperability of the tumor was demonstrated I pronounced the case as hopeless and advised strongly against further operative procedures.

Dr. Reuben Peterson saw the case later and confirmed in every way my statements. As the family and the patient insisted on giving her a last chance by abdominal operation he operated and found the condition beyond hope. The patient died 52 hours after operation.

It is here not the place to go into details of the pathology of this interesting tumor, as this will be published elsewhere. I would only like to point out here that it is a well-known fact that round-cell sarcoma of the ovary usually affecting both ovaries belongs to the most malignant diseases of the female generative organs, and that the rapidity of their growth is sometimes startling. Chroback[4] observed a case which grew within twenty-three days from the region of the navel to the border of the ribs. A similar case has been described by McBurney.[5]

At the close of my paper I would like to emphasize once more that, as shown on these instructive cases, vaginal explorative puncture and celiotomy is a valuable aid in the differential diagnosis of certain diseases of the female generative organs and may even be oftentimes of vital importance for the surgeon who bases his therapeutic actions on the old Hippocratic law: *Primum nil nocere.*

By its advocation is furthermore demonstrated the wisdom of the old, but in our days, unfortunately, too often violated law: Not to be carried away by every new idea, but to accept only that what appeals to judgment, and I would like to close with the precautionary words often cited by Gaillard Thomas[6] of New York, who, by the way, was one of the first advocates of vaginal celiotomy, as cited by Mackenrodt[7] in his paper: *Ueber den hinteren Scheidenbauchschnitt:*

"Be not the first by whom the new is tried,
Nor yet the last to lay the old aside."

Post-Graduate Hospital.

DISCUSSION.

Dr. H. J. Stacey, Leavenworth Kan.—We see many cases in which a vaginal puncture or free opening would relieve the condition and is without danger, whereas an abdominal section is out of the question. The occasional operator would take a chronic case and perhaps do well by the abdominal route; but the patient is frequently in too dangerous a condition for a major operation, at least in our hands, because we operate too slowly; but by draining first we can very

safely and easily do the major operation later by the abdominal route and save many lives in that way.

DR. D. H. CRAIG, Boston—I think cutting through a wall 8 to 10 cm. in thickness should be kept distinctly out of the field of vaginal opening. When we have pus so firmly walled off as that it is perfectly safe to go through the abdominal wall, then we can clean it out thoroughly and make a complete cure instead of leaving the patient with a lot of material to absorb. As regards the occasional operator, I think the vaginal route is better for him, providing he is sure of his technic. But no man can do more harm than the occasional operator going through Douglas' cul-de-sac into the abdomen. The posterior or anterior cul-de-sac operations are not, as a rule, curative. They are palliative, and if the occasional operator will take that route and do these operations it is incumbent on him to advise his patient of the fact that he is doing a palliative operation and that other work may be required by some one who is not an occasional operator.

DR. J. H. CARSTENS, Detroit—I wish the essayist would say "opening" instead of "puncture." A "puncture" means a little bit of an opening, and to my mind the opening can not be too big. A little one closes up right away, and you must do your work again. Make a good, big opening, and give Nature a chance.

DR. C. O. THIENHAUS—When I have a hard mass lying in the cul-de-sac of Douglas, and the diagnosis, whether or not this hard mass contains a focus of pus, can not be ascertained by other means, I advocated in my paper exploratory vaginal puncture for this purpose, and if I find pus I drain by way of the vagina. Dr. Craig says it is better to open the abdomen in such cases. Clinical experience has shown evidently that it is not. When you can not before operating determine the virulence of the bacteria present in the pus, you are liable, when a little of this pus contains highly-virulent infectious material, to see your patients die promptly. When bacteriology is so far advanced that we can determine with absolute certainty the grade of virulence of the bacteria in the pus focus, then we can differentiate and state in what cases abdominal section may be done without fear of infecting the general peritoneal cavity. But up to this time it is always better to be on the safe side and to open intraperitoneal abscesses, where there exists a possibility, by an extraperitoneal route. When the speaker says that cases of double pyosalpinx of gonorrheic origin do not heal by simple vaginal drainage, I would like to cite the statistics of Treub, who states that from 79 cases 44 were radically cured by simple vaginal drainage without further interference. I am sorry that Dr. Carstens misunderstood me. Naturally, when the puncturing needle has demonstrated the presence of pus, the vaginal incision must be as large as possible to establish free drainage.

CARCINOMA AND TUBERCULOSIS TREATED BY THE ROENTGEN RAYS.

G. E. PFAHLER, M.D.

Formerly Assistant Chief Resident Physician in the Philadelphia Hospital, Assistant Physician to the Medico-Chirurgical Hospital, Skiagrapher to the Medico-Chirurgical Hospital, Lecturer on Terminology and Symptomatology, and Demonstrator of Physical Diagnosis in the Medico-Chirurgical College.

PHILADELPHIA.

As a basis for the conclusions to be drawn in this paper, I have selected nine cases, each illustrating some special point of interest. I have omitted many of the details which would be of little interest to the general practitioner.

CASE 1.—Mrs. K. E., aged 84 years. Referred by Dr. Ulrich of Chester, Pa. The diagnosis was carcinoma of the right breast. Operation was contraindicated on account of the patient's age and on account of the condition of her heart. The growth was of one year's duration. There was a distinct retraction of the breast below the nipple, making a groove about two and a half inches in length. In connection with this there was a hard mass about the size of a hen's egg. Surrounding this central mass there were other masses of lesser size and of less density. The overlying skin was healthy. There was no axillary or supraclavicular involvement. Treatment was begun April 20, 1903, and exposures were given daily for two weeks. Each exposure was of ten minutes' duration, at a distance of 15 inches, with a high vacuum tube and 3 to 4 ampères' current. The treatments were then given three times a week for six weeks, then twice a week for ten weeks, and once a week for 2 weeks. She had 57 treatments in all. The length of each exposure was gradually increased from 10 to 25 minutes. After the first week there was improvement in that the semi-solid masses disappeared. At the end of two weeks the central mass seemed to be a little softer. From this time there was

Fig. 1.—Case 4. Before treatment by *x*-ray, May 25, 1903. Sarcoma of orbit. Scar due to an operation.

constant improvement, the mass gradually became softer and smaller until it disappeared.

The points of special interest in this case are the early and constant improvement, and the absence of any dermatitis in spite of the unusually long exposures. In no other case have I been able to give nearly so long an exposure without producing a marked dermatitis. As a whole, it is one of the most remarkable cases that I have seen.

CASE 2.—Mrs. K. J., aged 40 years. Diagnosis, recurrent carcinoma of the left breast. She had been operated on twice by Dr. Sanford of Memphis, Tenn. The first operation was performed one month after the growth was first noticed, May 7, 1900. A growth reappeared one year later and was removed December, 1901. A recurrence developed in July, 1902. *X*-ray treatment was begun in October, 1902, at which time there was

an induration involving the entire scar and about one inch on either side, with nodules in the axilla and the left supraclavicular region. There was also an induration in the right breast. Both mammary, axillary and supraclavicular regions were treated. Seventy-five treatments in all were given, between October 11 and May 31, when the carcinomatous tissue seemed to have disappeared. Treatments have been given since that time at intervals of two to four weeks for the purpose of preventing any recurrence or any involvement of the mediastinal glands. The patient's general health before treatment was failing and she was not expected to live six months. Her general health improved while under treatment. A dermatitis was produced on two occasions, each of which seemed to be followed by distinct improvement.

CASE 3.—Mrs. J. W., aged 48 years. Recurrent carcinoma of the left breast. She was operated on by Dr. Wharton in

Fig. 2.—Case 4. After thirty-four treatments. July 16, 1903.

June, 1902, one month after the growth was first noticed. The whole breast and axillary glands were removed. A recurrence was first noticed in November, 1902. *X*-ray treatment was begun Jan. 22, 1903. At this time nodules from the size of a pea to that of half a walnut were found scattered through the field of operation. A small indurated gland could be felt in the left supraclavicular region. Twenty-six treatments were given between Jan. 22 and April 7, 1903, when a burn of the second degree had been produced. The growth had lessened very much, both in size and induration. Treatment was discontinued. The thyroid gland, which was large at the beginning, now grew rapidly and the patient developed the symptoms of exophthalmic goiter. She was taken to the Presbyterian Hospital, where the burn healed, the thyroid gland decreased rapidly in size, and the general health improved. The patient then developed pain in the axilla, and Dr. Newcomet reapplied the rays, which produced another burn that developed after leaving the hospital. I advised her to go to the seashore and allow the burn to heal. While there a recurrence developed on the site of the burn without the burn healing.

This case to all appearances was similar to Case 2, but the results have been very different. It is an instructive case, because of the idiosyncrasy against the rays, since less rays were used than on either of the two previous patients. It also shows that a severe burn is no proof against carcinoma; also, that it is wrong not to keep a case under observation while a burn is healing, and that even when a good result is obtained the case should be watched.

CASE 4.—Miss D. B., aged 16 years. Referred by Dr. L. Webster Fox. This was a case of retrobulbar sarcoma, the diagnosis being confirmed by microscopic examination. The antrum of Highmore had been previously curetted by Dr. E. B.

Fig. 3.—Case 4. After forty treatments. Aug. 27, 1903. Scar due to an operation. Sight not disturbed.

Gleason. The growth again rapidly infiltrated the sinuses. The patient had been examined by Dr. Walter Freeman. She had also been examined by Dr. W. L. Rodman, who refused to operate and advised *x*-ray treatment. No one expected the patient to live. At the time of beginning treatment the patient was too weak to stand, complained of severe headache and pain in the eye. There was a marked bulging of the eye from the orbit and a protrusion of the conjunctiva. The case was treated daily with five-minute exposures, with a high vacuum tube, and 3 to 4 ampères of current, at a distance of 12 inches. At the end of a month the swelling had almost disappeared, the pain was less, and the patient was well able to walk around and left the hospital. There had been an erythema present for two weeks. She was then treated twice a week for a month, at the end of which time she could open her eye slightly, and felt fairly well. She was then treated once a week for two

months, when she was apparently well, except for occasional pain in the region of the inner canthus. She is still being kept under observation and occasional treatment. There was no loss of sight.

This case is important (1) because it was a sarcoma; (2) because of its extensive infiltration; (3) because of its prompt and constant improvement; (4) because there was no injury to the organ of sight as a result of the treatment.

CASE 5.—Mrs. A. S., aged 69 years. Epithelioma of the face. Referred by Dr. J. M. Anders, July 3, 1903. During the previous two months an epithelioma had been developing on the right side of the nose, and extended on the bridge of the nose. It was completely removed by 20 exposures, covering a period of two months. The cosmetic result is perfect. There is no scar, and the skin is smooth and of a pink color.

CASE 6.—Mr. S. G., aged 60 years. Epithelioma of the mucous membrane. Referred for *x*-ray treatment by Dr. Hollopeter. Ten years ago a warty growth developed on the lower lip. He began treatment at a sanatorium near Boston, July, 1900, where caustics were used. He remained there 18 months, at the end of which time he came to Dr. Hollopeter and was referred to me. His mouth could then not be opened except to admit the little finger, and this gave him severe

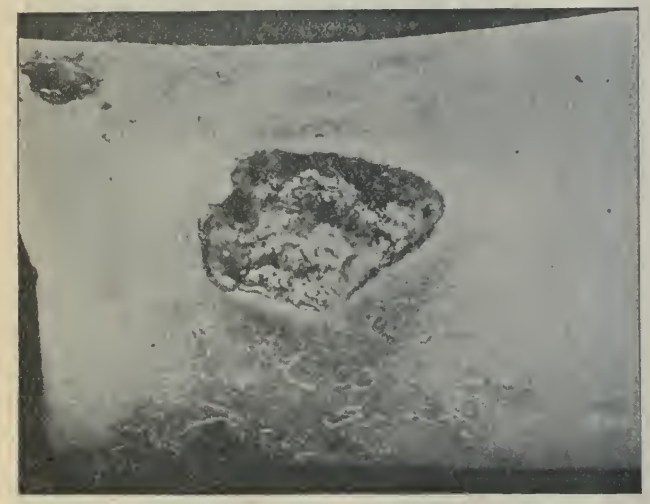

Fig. 4.—Case 8. Tubercular ulcers of the leg, March 3, 1903, before *x*-ray treatment.

pain. The growth involved the right angle of the mouth and the greater part of the cheek. There was an enlarged gland in the right submaxillary region. The gland disappeared in about a month under treatment, but the growth itself, being mostly in the mouth, slowly but gradually increased in size and the amount of pain increased. The case was inoperable from the first, but the rays had little influence except perhaps to slightly retard the growth. Ninety treatments were given.

Cases 5 and 6 are important because of their differences. In Case 5 the epithelioma was entirely superficial, involved the skin, had never been tampered with by caustics, was treated early with the *x*-rays and yielded promptly with perfect results. In Case 6 the epithelioma was not entirely superficial, involved the mucous membrane, had been tampered with by caustics for eighteen months, *x*-ray treatment was begun late, after the growth had started to spread, and a long course of treatment was given with practically no results.

CASE 7.—Miss A. N., aged 20 years. Tuberculous adenitis. Referred by Dr. Ernest La Place. She had had tubercular adenitis for nine years and had been operated on by Dr. La Place three years ago, and again one year ago. She was referred for *x*-ray treatment Feb. 9, 1903, on account of swelling of the glands on both sides of the neck and because of an indurated scar on the right side of the neck. After 10 treatments the scar and the glands were softer. After six weeks and 15 treatments the scar had almost faded and the glands were almost imperceptible. After 5 months and 34 treatments the glands were imperceptible, and the scar was soft, pink and barely noticeable.

CASE 8.—Miss J. F., aged 16 years. Referred by Dr. W. L. Rodman, March 3, 1903. Diagnosis, tuberculous adenitis and tuberculous ulcers of the legs. She was operated on by Dr. Rodman one year ago, when the glands were completely removed from the left side of the neck, from the lower portion of the right side of the neck and from the right axilla. At time of beginning treatment there was enlargement of the posterior cervical glands and a distinct enlargement just below the right ear. There were also three ulcers on the right leg, varying in size from one inch to two inches in diameter. She has been given 40 treatments covering a period of eighteen weeks. The two smaller ulcers on the leg healed within a month. In six weeks the largest gland had ruptured and healed. At the end of four months the enlargement of the glands had disappeared. The largest ulcer on the leg had

Fig. 5.—Case 8. Oct. 12, 1903. Ulcer healed, scar still red.

been reduced to one-third its original size, and had a healthy appearance, but needed support of the circulation. Dr. Burns then applied an elastic cast and the ulcer healed in three weeks.

The above two cases are important because they show undoubtedly a good influence of the rays on the tuberculous glands and ulcers.

CASE 9.—Miss K. B., aged 30 years. Referred by Dr. La Place, under whose care she had been for fifteen years. Diagnosis, lupus vulgaris. At the time of beginning treatment, the diseased area covered the greater part of the anterior portion of the face and the entire nose. A distinct reaction was produced in two weeks by 7 exposures. Following this reaction the tubercles were leveled to the skin and desquamation took place. She has been given 18 treatments in four months, and is practically well.

I report this case because of a very interesting and remarkable coincidence. For eight years previous to beginning treatment, the patient had been very deaf, so that it was difficult to make her hear. At the end of the course of treatment, she could hear ordinary conversation. This remarkable result was unthought of and, therefore, no accurate observation had been made before treatment; but eight years ago a specialist in

New York had examined her and pronounced her deafness incurable. This result suggests that the rays may be of value in some forms of deafness.

In conclusion, I am convinced that:

1. The *x*-rays are of undoubted value in the treatment of certain cases of both superficial and deep-seated carcinoma and tuberculosis.

2. The more a case has been tampered with, the less likely it is to yield to the influence of the *x*-rays, *e. g.*, Case 6.

3. Daily treatments carefully and properly given will produce the best results, *e. g.*, Cases 1 and 4.

4. We should try never to produce a dermatitis beyond a simple erythema.

5. There are idiosyncrasies in certain people which render them most susceptible to the *x*-rays, and in these people deeper burns may occur in spite of the most careful treatment, *e. g.*, Case 3.

6. Epithelioma involving the mucous membrane is much less likely to yield to the effect of the *x*-rays than when it simply involves the skin, *e. g.*, Case 6.

7. There is not likely to be any interference with the sense of sight, even though the *x*-rays are used directly over the eye, *e. g.*, Case 4.

8. Tuberculosis, whether of the skin or of the glands, will yield at least in certain cases to the effects of the *x*-rays, *e. g.*, Cases 7, 8 and 9.

9. The *x*-rays may be of value in certain cases of deafness.

10. The *x*-rays will give better cosmetic results than any other form of treatment in simple epithelioma of the face, *e. g.*, Case 5.

11. Epithelioma of the mucous membrane should be removed as early as possible by the knife, and this followed by *x*-ray treatment.

12. Operable cases should be operated on and in each instance followed by a course of *x*-ray treatment, and *x*-ray treatment should be given at the first sign of a recurrence.

13. Inoperable cases should be given a trial with the *x*-rays, since even hopeless cases sometimes yield to this form of treatment, *e. g.*, Case 4.

14. It is desirable to produce a distinct reaction in the treatment of lupus, *e. g.*, Case 9.

Clinical Reports.

TWO CASES OF TRANSITORY COMPLETE BLINDNESS OF BOTH EYES.*

CHARLES J. KIPP, M.D.
NEWARK, N. J.

IDIOPATHIC OPTIC NEURITIS.

Case 1.—Mrs. K. S., aged 32, has been married eleven years, and is apparently in robust health. She has given birth to two children, both of whom are living and in good health; the younger is 4 years old. Patient has always been in good health. No history of syphilis. For some weeks she has suffered more or less from frontal headache.

She came to the Newark Eye and Ear Infirmary for the first time Dec. 22, 1901, complaining of loss of vision of left eye and impairment of vision of right eye. The examination made at this time showed that the exterior parts of the eye were perfectly normal in appearance, and that the movement of the eyes were unimpeded in any direction. On closer examination it was found that the left eye was blind; this eye could not distinguish between light and darkness. The pupil of this eye was larger than that of the right eye and it did not react to light. It did, however, respond to light thrown in the right eye. The ophthalmoscope showed clear media and a well-marked papillitis. The optic disc was swollen and apparently enlarged. The retinal veins were full and tortuous, while the arteries were of about normal caliber. The retina immediately surrounding the disc was hazy, but otherwise it was normal. The right eye also showed swelling and enlargement of the optic disc, but not quite so marked as that of the other eye. The retina was transparent except very close to the optic disc. The pupil of the right eye was of normal size and responded readily to light. The sight of this eye was reduced to 5/12. An examination of the urine showed it to be free from albumin and sugar. Close questioning failed to reveal disease in any other part of the body.

She was given iodid of potassium in small doses. She was seen again the next day, when it was found that both eyes were now totally blind. She could not recognize the light of a candle held close to her eyes. The swelling of the optic discs had increased. Their surfaces were best seen with a +3 dioptric glass. The pupil of the right eye was now as large as that of the left eye, and neither pupil reacted to light.

She remained in this condition until December 28, when she could distinguish between light and darkness. December 30 it was found that the pupil of the right eye responded very sluggishly to light, but contracted in convergence. The pupil of the left eye responded even more sluggishly than the right eye to light, but also contracted in convergence. She can see movements of hands in front of her eyes, but can not yet count fingers close to her eyes. She was at this time taking fifteen grains of the iodid of potassium three times daily.

Jan. 8, 1892, it was found that the pupils of both eyes reacted to light in convergence fairly well. The vision of both eyes remained about the same as at last, January 14. Can now count fingers with either eye at four or five feet. She still has frontal headache. The optic discs are less swollen and the retina adjoining the disc is more transparent.

January 22: Her vision is now 5/18 in the right eye and 5/36 in the left. The visual field is intact in both eyes. She is taking twenty grains of the iodid three times daily. After this time her vision gradually improved so that on February 5 it was 5/9 in either eye. The discs were now almost flat and quite white. The headache had subsided.

March 15 her vision was about normal in both eyes and the visual field intact in both. During the following five years I saw the patient at intervals of several months and always found her in good health. Her vision when I last examined her five years after the attack was normal in both eyes and so were the visual fields. Her health was excellent. I have been trying to find her since, but have not succeeded in so doing.

The absence of the pupillary light reflex for a while made it probable that the seat of the lesion was in the visual tract, this side of the corpora quadrigemina.

The visual centers may also have been involved, but this can not be proved, as the conduction of visual impressions was interrupted by disease of the tract. The ophthalmoscope showed the existence of a marked optic neuritis in both eyes. Cases in which an optic neuritis has caused total blindness of both eyes and in which the pupillary light reflex was absent for a time, with subsequent restoration of normal vision, and very seldom encountered. With the exception of a frontal headache my patient was in excellent good health at the time the optic neuritis developed, and as she remained in good health during the next five years it seems reasonable to assume that the eye disease was not the result of a general affection which was latent when she became blind.

AMAUROSIS, PROBABLY FROM AUTOINTOXICATION.

Case 2.—Mrs. S., aged 52, stout, of typical bilious temperament, is subject to frequent attacks of headache; is constipated most of the time; is fond of rich food and indulges freely in eating.

July 27, in the evening, she was attacked with a sudden intense pain in the head, with nausea and vomiting. The attack was so severe that her attending physician was obliged to give her ¼ grain of morphin hypodermically. She was re-

* Read at the one hundred and thirty-seventh annual meeting of the Medical Society of New Jersey.

lieved in about half an hour. Calomel and Warburg's tincture were given next morning, but did not act well. In the evening of this day, at about the same hour as on the previous day, another severe attack of headache came on and another dose of morphin was given her, which gave her some relief.

On the morning of the 29th she was given one ounce of Warburg's tincture, and in the evening she received ten grains of quinin. She had no attack of headache on this day.

On the 30th, in the evening, she had another very severe attack of headache. In the morning of this day she had taken ten grains of quinin and ten more in the evening. During the night of the 30th she noticed that her vision was becoming impaired, and on the morning of the 31st she was totally blind in both eyes. Pupils reacted but feebly to light. I saw her for the first time shortly after noon on this day. She acted like a person who was absolutely blind and was quite self-possessed. I found that the movements of the eyeballs were unimpeded in any direction. She was unable to recognize the position of a lighted candle held but a short distance from her eyes. The pupils of both eyes responded readily to light and in convergence. The ophthalmoscope showed absolutely normal eye grounds. In one of her eyes she had a patch of opaque nerve fibers such as is frequently seen in eyes with good vision. There was absolutely nothing hysterical about the woman. I feel very confident that she did not exaggerate her impairment of vision. The hearing was normal. I made a favorable prognosis. An examination of her urine showed it to have a specific gravity of 1030; it contained a trace of sugar, but no albumin. The quantity of urine passed during the day preceding the blindness is not accurately known, but it was said to have been of the usual amount. The bowels had not moved freely for some days, although sulphate of magnesia in large doses had been administered at frequent intervals. A high enema was given shortly after I saw her, which brought away a quantity of fecal matter, in which, on examination, were found seeds of berries eaten two weeks before. The total blindness continued for thirty-six hours, and then gradually her vision returned in both eyes. There was no rise in temperature during the attack, but on the day following her temperature rose to 102. A week after the attack her vision was as good as before the attack, and the visual fields were of normal extent for white and colors in all directions.

All our efforts to find a cause for the sudden blindness was fruitless. She has no disease of the kidneys. Habitual constipation, for which she always was taking cathartic mineral waters, was about the only abnormal condition which we could discover at the time. She has been in her usual good health ever since.

That this was a case of amaurosis from some kind of intoxication there can be no doubt. But as to whether it was due to a poison introduced into the body from without or whether the poisoning was the result of an inadequate physiologic elimination of the product of the tissue metamorphosis or of the formation of a poison in the intestinal tract due to abnormal processes of decomposition or fermentation, must remain in doubt. That the poison was not introduced from without seems, however, pretty certain. Neither the food of which she had partaken nor the drugs which had been administered can be held responsible for the eye affection. We know that quinin in comparatively small doses will occasionally produce blindness, but both the clinical features and the absence of all change in the backgrounds of the eyes, as well as the subsequent history of the case, show that this drug was not the cause of the blindness. The absence of disease of the kidneys probably eliminates uremia as the cause of the amaurosis, though it must be admitted that this attack closely resembles in all its features the blindness known to occur in this affection. In one of the examinations of the urine a trace of sugar was found, but only once, and none has been found since the attack. With the exception of habitual constipation, there is no evidence of the presence of a morbid affection of the digestive tract, and yet the most plausible explanation seems to me to be that the toxin which caused the amaurosis was formed here through putrefactive changes of the contents of the intestinal tract. As to the part of the visual apparatus affected in this case, there can be no doubt. The blindness with prompt pupillary reaction to light established the fact that the optical centers were the seat of the lesion. But as to whether it was an edema of the meninges or an affection of the brain itself no one can tell. There are very few cases on record similar to the one here described, and in most of these the absence of albumin in the urine was not positively excluded. I am indebted to Dr. Cladek of Rahway for notes of the previous history of the case.

To recapitulate: In both of the cases above reported the blindness was due to an affection of the nervous visual apparatus. In the first the seat was in the conducting apparatus, as was manifest from the fact that the pupillary light reflex was absent during a part of the time that the blindness existed. In the second the seat of the lesion must be looked for in the optic centers, as the pupils reacted promptly to light while total blindness was present. In both cases the vision was completely restored. It is doubtful that the treatment adopted had anything to do with the restoration of the sight in either case.

I. PROLONGED INTUBATION. II. ESOPHAGOTOMY FOR A DENTAL PLATE. III. LARYNGECTOMY FOR CARCINOMA.*

GEORGE F. COTT, M.D.

CLINICAL PROFESSOR OF OTOLOGY, UNIVERSITY OF BUFFALO

BUFFALO, N. Y.

I.—A CASE OF PROLONGED INTUBATION.

One of the rarest accidents following intubation for diphtheria is stenosis, which results from pressure ulceration of the subglottic region and is very difficult to remedy. There are, perhaps, half a dozen cases on record; several made complete recoveries. One of these is as follows:

Intubation.—Rosa McGlynn, aged 6, was taken sick with diphtheria in December, 1901, and in a very few days required intubation. Being otherwise engaged, I sent my assistant, Dr. James E. King, to perform the operation. A week later the tube was removed, but had to be replaced immediately. Several days thereafter I removed the tube, but within a very few minutes had to replace it. This occurred frequently for several weeks. In order to keep better watch of the child I had her removed to the Riverside Hospital, and there the tube was removed and replaced off and on for several months.

Excision of Stricture.—Being satisfied that intubation would do no further good, especially since it had become necessary to use a one-year tube, I split the larynx completely and found a fibrous stricture below the vocal cords in the subglottic tissue. This was cut out and considerable granulation tissue removed with a sharp spoon, and a silver tube passed up from the tracheal wound between the vocal cords and the larynx, and a tracheal tube downward through which the child breathed. These tubes were left in for some time, when intubation was again resorted to, but gradually the lumen was again diminished until it became very difficult to insert a one-year tube. The larynx was opened a second time and the stricture removed as before. The upper or laryngeal tube was not replaced, but the lower or tracheal tube was allowed to remain for several weeks. Intubation was intermittently performed during this time.

Course.—After a while the tracheal tube was removed and the child allowed to go several days without a tube, but occasionally she had to be intubated, on very short notice. The interne was instructed to be on his guard either to intubate or to do tracheotomy on a moment's notice. About 2 o'clock one morning he was suddenly summoned and found the child suffocating. Dr. Weed hurriedly opened the trachea and the danger was tided over once more. After that I opened the larynx for the third time, removed the stricture again and

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

continued to intubate with a large tube at lessened intervals until June, 1902. The child had now been intubated, during six months, over fifty times by Dr. King, Dr. Weed and myself, and tracheotomized half a dozen times. She was retained at the hospital several weeks after the last time the tube was removed, when her mother took her home.

After we had not heard from her for six months, we called on her, and found her in good health, grown fat, and her voice in perfect condition.

The patient came under my care while I was city physician. The family was poor and the surroundings very unclean, so she was removed to the hospital. We had several times intended to send her home with the tracheal tube, but for one reason or another she was kept at the hospital until finally it was thought safe to let her go with her mother.

Comments.—This case is another illustration of what perseverance may accomplish. Ordinarily after two or three months such a case would have been abandoned as positively incurable, and the child would have to wear a tracheal tube all her life. Dilatation certainly would have been practiced, but without avail. The stricture was altogether too firm to yield to pressure. Each time after the radical treatment the child reacted remarkably, in fact was up and playing the very next day.

We had all sorts of tubes made, of different sizes and shapes, without the slightest benefit. It is very seldom that intubation can be shown a class of students. I therefore thought this a good opportunity to demonstrate the operation, the little patient always being in readiness. Tubes were tried from six years down to one, but to my chagrin, and apparently to the students' amusement. The smallest tube could not be forced through the larynx. The result was more trying because I had told the class (about forty in number) how simple an operation it was. Not until long after the boys were being entertained by another teacher did I succeed. Two men from out of the city were in attendance at the lecture; after watching the performance a while they finally left in disgust. Failure to replace the tube, however, was a common experience to Dr. King and myself. We sometimes tried ten or a dozen times without accomplishing our object, only desisting when the child became exhausted.

This case is worth reporting on account of its rarity, as well as showing the recuperative power of the larynx.

II.—ESOPHAGEAL OBSTRUCTION CAUSED BY SWALLOWING AN UPPER ALVEOLAR PLATE.

History.—Woman, aged 35, had worn an upper alveolar plate of hard rubber containing on one end one, and on the other end two teeth. The outer one of the two had been separated from the plate leaving the two pins which held it exposed. The plate had sharp edges throughout. It was worn by the woman continually day and night for fifteen years without ever becoming displaced.

One day while at dinner the plate suddenly became loosened and was carried down the esophagus with a bolus of food. It caused her considerable pain, for the relief of which she sent for her physician, Dr. Hugh McIntyre, after having ineffectually tried to dislodge it. He called me in consultation. I advised having the plate located by means of the *x*-rays, which was done by Dr. Fred Preiss. The plate was found immediately behind the sternal notch. The center of the plate was two and one-quarter inches below the thyroid cartilage. The teeth in the plate were anterior; curve of plate was downward; ends of plate were lateral; higher on the right side than on the left by one quarter of an inch.

Operation.—Dr. Kenerson, a surgeon, was asked to see the patient, and the woman was informed that the plate would have to be removed by operation, to which she readily consented. She was removed to the Riverside Hospital. I made an incision on the outer side of the trachea and separated the tissues between the muscles and carotid sheath until I came down to the esophagus, which was properly located and opened. Dr. Kenerson then introduced through the esophageal opening a pair of forceps and gradually and carefully drew the plate into view, which I then grasped and rotated through the wound. The esophageal opening was then sutured and the rest packed with gauze. We anticipated a fistula, therefore did not entirely close the outer wound. Two days after the operation saliva passed out of the wound, which continued for nine days, when the wound closed. No food had passed down the esophagus during that period.

Course.—The patient was very much emaciated at the time of the operation, having had the care of four little children, one of which she was still nursing. There was, of course, some doubt about the woman's recovery because of her extreme debility. She was nourished by rectal injections and cod-liver oil baths until the esophageal fistula closed. It was carefully dressed after the second day, to heal it up as rapidly as possible. She took very kindly to nourishment. At the end of three weeks she was discharged cured, vowing never again to wear another plate.

III.—PARTIAL EXTIRPATION OF THE LARYNX FOR CARCINOMA.

History.—Mrs. S., aged 55, complained of hoarseness for the past year, breathing then became so oppressive that she finally sent for Dr. Weil, who treated her for two weeks, when he sent for me to examine her throat. I found a large growth involving the entire left lateral thyroid cartilage and infiltration of the right arytenoid.

Tracheotomy.—The examination produced a spasm of the glottis and I thereon proposed tracheotomy, but the patient's son being informed of the necessity of cutting a hole in her throat, positively refused to have this done. I therefore left word to send for me when they were ready to have the windpipe opened. The next day I was summoned, and, after injecting a small quantity of a 1 per cent. solution of eucain, opened the trachea without much difficulty.

Up to the time of the operation she had had seven or eight spells of suffocation every night for two weeks, her pulse was very rapid and she was extremely weak and emaciated. A week after the tracheotomy she had improved so much that I was enabled to remove a small piece of the growth for microscopic examination. This was made by Dr. Bentz of the Pathological Laboratory of the University of Buffalo, and he reported as follows:

"*Microscopic Examination.*—Parts of the tissue are covered by stratified squamous epithelium. The epithelium dips down deeply into the tissue (fibrous) beneath. The epithelial cells have broken through the basement membrane and infiltrated the tissue, along the lymphatic clefts. These infiltrations are in the form of columns or groups of small and large spherical cells, atypical epithelium. Hyperkeratosis, hyperchromatosis, and mitosis were found in the cells. In some groups the cells show cornification and flattening and are arranged concentrically forming so-called 'pearly bodies' or 'cell nests,' characteristic of epithelioma. There is a marked inflammatory process in the tissue between the groups of atypical cells, as is shown by round cell infiltration.

"On these histologic findings an anatomic diagnosis of squamous celled carcinoma epithelioma was made."

I informed the patient of the serious nature of her trouble, and that the only possible chance of a cure was excision. Arrangements were made for operation four days later.

Operation.—August 5 an incision was made three inches in length, the thyroid cartilage was separated from its attachments, anticipating the removal of the entire larynx. After the larynx was opened for inspection, it was found that the swelling on the right side had entirely disappeared.

Being satisfied that only the left side was involved the thyroid and part of the cricoid cartilage were removed. The wound was then packed and a tracheal tube inserted. The operation took 50 minutes. No glandular structures were found enlarged.

Course.—The patient made a speedy recovery and was walking about the hospital in three days. Owing to the separation of the thyroid attachments there was so much narrowing that it became necessary for the patient to wear the tracheal tube permanently. Four months after the operation the patient complained of difficulty in swallowing, and for two weeks this continued with more or less severity, forming

a large swelling in the neck. From the amount of involvement of this secondary invasion, I was satisfied that removal was out of the question.

Recurrence was hardly expected so soon after operation. No glands were felt nor was there any indication that the disease had gone beyond a limited area. There had been up to this time a few cases recorded of successful treatment of carcinoma by the Roentgen rays. I therefore recommend that treatment, telling her at the same time that further operation was worse than useless. She went to the Buffalo General Hospital and there received treatment every other day. After the eleventh treatment I saw her again, and the growth had entirely disappeared, the parts looking normal. She had in all 16 treatments, and now, May 1, so far as outward appearances go, is entirely well.

DISCUSSION.

DR. B. R. SHURLY, Detroit—In looking over the literature of this condition throughout the world, I find that some observers report a 1 per cent. difficulty in removing the tube. While the tube is ordinarily removed in four days, we sometimes find it necessary to retain the tubes in place as long as a year. There are two cases in the Willard Parker Hospital now wearing the tubes more than a year. The etiology must be explained largely from the standpoint of traumatism. We have through traumatic conditions, which are frequent, an ulceration in the subglottic tissue due to the pressure of the tube in that region, or an ulceration in the anterior tracheal wall in the region of the lower border of the tube, or along the epiglottis at the head of the tube. A method of extraction which I find obviates much of the difficulty is the application of astringents to the intubation tube before again introducing it into the larynx. The spasmodic condition is due to an irritation of the laryngeal nerve endings, and we have frequent intubations and extubations with consequent injury. By applying ichthyol around the tube, alum gelatin or ointment the tube may be removed with comparatively little difficulty. This opens up a wide field for the treatment of the larynx in these conditions. We can use ichthyol, alum, argyrol, nitrate of silver, protargol, or suprarenal extract. An anodyne should be administered a half hour before extubation, thus keeping the child at perfect rest, and there will be comparative ease in removing the tubes. Ordinarily tracheotomy should not be performed. As O'Dwyer stated in a paper written shortly before his death, a condition of subglottic stenosis is almost certain to occur.

DR. D. A. KUYK, Richmond—I wish to report a case that shows how possible it is to make an error, especially without the desirable apparatus. I was called to see a woman who said that she had swallowed a set of artificial teeth. She had swallowed nothing for several days, was pale and nervous and had slept neither day nor night. At that time, ten years ago, we did not have the *x*-ray apparatus. I used an esophageal tube to ascertain the location of the foreign body. The esophageal bougie passed on down to the stomach without difficulty. I assured her that there was nothing in the esophagus, and that there was nothing but fear and fright. It was a case of autosuggestion about which Dr. Loeb will tell us. Afterward we found the teeth beneath the refrigerator, and in a few days the woman had entirely recovered.

DR. OTTO T. FREER, Chicago—The choice of esophagotomy for removal of the foreign body mentioned was, I think, a wise one. If a substance with sharp, jagged edges has been impacted for some time in the esophagus, extraction by the natural passages becomes hazardous, as it is impossible to tell how much damage has been done by ulceration or even by perforation of the esophageal walls by the pressure of the pointed prominences of the foreign body. Attempted removal through the mouth is apt to tear or perforate the ulcerated and softened esophageal wall with consequent peri-esophagitis, deep phlegmon of the neck, dangerous hemorrhages and mediastinitis. The patient encounters less risk in these cases from external esophagotomy, which does no violence to the esophagus and provides free drainage for peri-esophageal septic processes.

DR. GEORGE F. COTT, Buffalo, N. Y.—These stenotic conditions after diphtheria are almost always due to traumatism. There may be some exception in constitutionally weak children, when the tube presses on the muscles forming the vocal cords so much that they suffer collapse and sudden death follows, as I have seen in perhaps a half dozen cases. The percentage of stenosis is no doubt as high as Dr. Shurly mentions, but the percentage of these extreme cases is very minute. I have had a patient in whom granulation tissue formed almost throughout the trachea. A boy aged 2½ years at first had worn a tube suitable to his age, but having coughed up successive tubes, by the end of four weeks he was wearing one for a seven-year child. The trachea was then opened, and intubation practiced intermittently. The trachea was opened radically several times by Dr. Roswell Park at the General Hospital, but reproduction rapidly followed and tracheotomy had always to be resorted to. At the age of 10, seven and one-half years after the first intubation, he coughed up the tracheal tube and suffocated before aid could be rendered. These are the only really severe chronic stenoses I have met in 108 intubations.

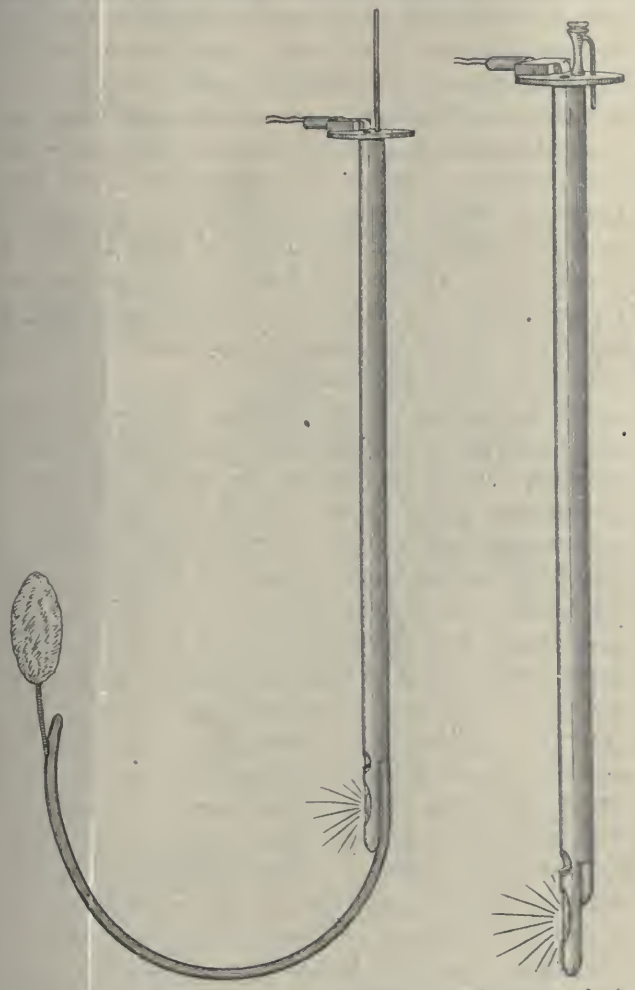
TRIPLE MAJOR AMPUTATION WITHOUT LIGATION OF THE BLOOD VESSELS.

WILLIAM B. PATTON, M.D.
SPRINGFIELD, OHIO.

The following unusual case has proved interesting to the local profession and may therefore be of general interest:

M. B., aged 8, was run over by the steam cars, Sept. 16, 1903. He was taken to the Mitchell Thomas (City) Hospital, where Dr. F. P. Anzinger and I examined him. The right hand was crushed and the arm was hanging by the skin three inches above the wrist; the right foot was crushed to the ankle; the left foot was hanging by shreds three inches above the ankle. There was also a laceration of the scalp as well as a number of contusions on the back and thighs. There was no evidence of any considerable loss of blood and the boy suffered comparatively little from shock. Dr. Anzinger amputated the right leg while I removed the left. To secure sufficient flaps it was necessary to reamputate each limb far enough above the point of the injury so that the vessels could not have escaped being cut. After completing the flaps, we each proceeded to look for the blood vessels. The larger vessels not being in evidence the tourniquets were slowly removed, but there was no hemorrhage. After searching for some time for the vessels we covered the stumps and proceeded with the arm. Here we found and ligated two small superficial spurters, but neither the radial nor ulnar arteries were found. We completed the dressing of the arm, suturing the flaps and again examined the legs, but found neither hemorrhage nor signs of pulsating vessels. We packed the stumps without suturing the flaps and put the patient in bed. Forty hours later we removed the dressings and found no more oozing than is usually found in such cases, if as much. We sutured the flaps on the legs at this time. There has never been a sign of hemorrhage. All the flaps became infected, but have healed nicely by granulation. Two large abscesses formed on the patient's back and one on his thigh at sites of contusion. Barring these complications, he has made an uninterrupted recovery and is now sitting up in a wheel chair apparently in good health.

New Instruments.



A COMBINED GASTROSCOPE AND GYROMELE FOR DIAGNOSTIC AND THERAPEUTIC PURPOSES.

FENTON B. TURCK, M.D.
CHICAGO.

Gastroscopy is used to determine the condition of the mucous membrane of the stomach by inspection. For this purpose a stiff tube is used with an electric light at the end and a reflector to carry the image to the eye through a system of lenses within the tube.

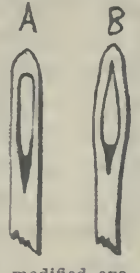
The method of such examination demands the use of a long, straight, rigid tube reaching far into the stomach. The possibility of introducing a long, stiff, straight instrument has been shown to be possible in the exhibitions made by sword swallowers. Leube[1] recommended a stiff sound introduced into the stomach to be palpated through the abdominal wall for the purpose of determining dilatation of the stomach. When it was found practical to introduce a stiff, straight instrument into the stomach the idea of inspection of the gastric cavity through a hollow, straight tube naturally presented itself.

Mikulicz[2] was the first to illuminate the stomach and make the mucosa visible by the use of the gastroscope. Mikulicz[3] showed that it was practical and useful in the diagnosis of ulcer and carcinoma of the stomach. Owing to the technical difficulties, the high price of the instrument and the great discomfort to the patients, Mikulicz's instrument has not been much employed. With more familiarity with intra-

gastric work inspection of the interior of the stomach is more easily accomplished. Thus Rosenheim[4] asserted that in 80 per cent. of the cases it was possible to introduce the gastroscope and inspect the stomach without great difficulty. Kuttner made some modifications in an instrument which was presented before the British Medical Association, Edinburgh, 1898, by Professor Ewald. Careful inspection of this instrument at that time by the writer convinced him that the large round caliber (1.5 cm.—9/16 inch or more), which was necessary under such construction, added much to the difficulty of using this class of apparatus, which at best is an inconvenient method and not devoid of danger.

When we remember that a sword swallower may repeatedly swallow a sword without apparent difficulty and rarely with any harm there must be some reason other than familiarity with the procedure. Patients become inured to the passage of intragastric instruments depending on the shape and size of the caliber. The shape of the esophagus is flattened anterio-posteriorly to that a flat, sword-shaped instrument, even though rigid, can be readily introduced into the stomach. There is in a flat instrument less pressure exerted on the cricoid cartilage, the laryngeal nerves are not so much excited, and less tension is produced.

The instrument which I have devised is composed simply of a flattened double tube 65 cm. in length. The optical tube is slightly larger in caliber than the other, or carrying tube, being 5 mm. in diameter. The two tubes side by side form a width of 14 mm. Beyond the tip of the optical tube is inserted the electric lamp which requires no cooling apparatus. Above this a prism and reflector is adjusted at an angle. The outer, or ocular, end is provided with the usual prism set before the objective. The other tube is to carry the gyromele cable, which can be used to sound the pylorus or duodenum by inspection instead of by palpation as I first recommended[5] in 1894. The gyromele cable may be curved by a simple mechanical contrivance previously recommended[6] in any direction desired. Thus the pylorus may be explored by the very soft flexible cable covered at the end with wool tampon encased by a soft rubber finger cot. As will be seen in the illustration the flexible curve, the soft rubber tube carrying the flexible cable, acts as a protection to the stomach during any sudden contraction of the abdominal walls, preventing the gastric wall from being suddenly thrown against the end of the upper and rigid portion of the gastroscope. It will be seen briefly this apparatus is a combination of the principle of my double stomach tube and the gyromele with the addition of an improved gastroscope.



I have been able with this instrument to inspect the pylorus, and under the direction of the eye watch the gyromele cable pass through the pyloric orifice into the duodenum. Withdrawing it back and forth one can readily watch the distance it passes into the intestines. The measurement can be made by small nodes on the cable set 10 cm. apart. I hope in a later communication to present the practical use of this instrument not only as a diagnostic aid but also in making application to specific points on the gastric mucosa.

A MODIFICATION OF THE EYE OF THE NEEDLE.

JAMES P. MARSH, M.D.
TROY, N. Y.

During the process of suturing I have been frequently very much annoyed by the needle unthreading. To obviate this difficulty I have had needles made with eyes differently formed from the ordinary, the object of this modification being to so join the suture material into the narrow part of the eye that

A, Ordinary eye; B, modified eye, enlarged 2½ times.

it will not become unthreaded by reason of any ordinary traction and at the same time to so leave it that it can be readily loosened at the end of the suturing for the purposes of tying. The drawing presented will best show the modification made. It is possible that the same means has been previously resorted to, but not to my knowledge.

THE DETECTION OF TYPHOID BACILLI IN WATER.

Although the evidence that connects sewage-polluted water supplies with outbreaks of typhoid fever is entirely convincing both in character and mass, there have been relatively few instances in which bacteriologists have succeeded in isolating the specific typhoid bacillus from suspicious waters. In view of the insufficiency of the data relied on for identification, most of the early statements concerning the finding of the typhoid organism must be regarded as of exceedingly doubtful value. The criteria on which up to a very few years ago such identification was based could by no means be accepted by bacteriologists at the present time. Especial uncertainty again has been recently introduced into the subject by the discovery of the group of dysentery and "pseudo-dysentery" bacilli, of *B. fecalis alcaligenes* and of a host of related organisms.

A survey of the literature shows that there are very few reported cases of the detection of typhoid bacilli in water which conform to present-day requirements. Lösener,[1] working in the Hygienic Institute at Berlin, isolated from the laboratory water supply an organism that agreed culturally with the typhoid bacillus in all respects, and that also responded favorably to Pfeiffer's immunity test. Remlinger and Schneider[2] found in various natural waters organisms that possessed the biologic qualities of the typhoid bacillus, and that agglutinated with typhoid serum and also conformed to Pfeiffer's immunity test. Some conservatism is shown, however, in accepting the work of these latter authors at its face value, both because of their rather sweeping statements with regard to "the ubiquity of the typhoid bacillus" and because of certain other internal evidence in the paper referred to. Hankin,[3] working in India, found typhoid-like bacilli in samples of water derived from various sources, and substantiated his cultural examination with the observation that agglutination occurred with a 1-600 dilution of anti-typhoid serum. Kübler and Neufeld[4] relate a particularly interesting case of the finding of typhoid bacilli in the water of a shallow well to which infection had been traced. In the course of the investigation it was noticed that no colon bacilli were present in the water, a fact that in the opinion of the authors points to infection with typhoid urine rather than with fecal discharges, and that explains the relative ease with which the typhoid bacillus was isolated, as well as the unusually long persistence of the organism in the water. Both the agglutination test and Pfeiffer's test were employed to establish identification. Genersich[5] isolated eleven cultures of typhoid-like bacilli from the water of incriminated cisterns. These organisms agglutinated in a dilution of 1-50 with typhoid serum obtained from a human patient, but the serum of animals inoculated with the water cultures failed to agglutinate a control typhoid culture except in a single instance. Fischer and Flatau[6] have reported an apparently unimpeachable case of the isolation of the bacillus from the water of a well at Rellingen. Both the agglutination test and Pfeiffer's test were applied with positive results.

There are, therefore, perhaps six cases where undoubted typhoid bacilli have been isolated from ordinary drinking water. If the evidence adduced by Remlinger and Schneider and by Genersich is not regarded as wholly convincing, the number of such cases is reduced to four. On the other hand, the finding of a paratyphoid bacillus in water by Sion and Negel[7] may be put practically in the same category with the discoveries of genuine typhoid bacilli.

The meagerness of the findings, despite the thousands of examinations that have been made by skilled bacteriologists in every part of the world, can probably be explained partly by the difficulties of the technic of isolation and partly by the relatively short duration of life of the typhoid bacillus in water. The period elapsing between the moment of infection and the initiation of bacterial investigation is usually at least several weeks, owing chiefly to the time occupied in incubation and in the insidious development and perhaps tardy recognition of the disease. Some time is also ordinarily consumed by the preliminaries necessary for the setting on foot of competent investigation. It is apparently only under exceptional conditions, such, for instance, as obtained in the instance reported by Kübler and Neufeld, that the life of the bacillus can extend throughout any considerable period. The history of most outbreaks of typhoid fever shows that the bacilli have disappeared from the water by the time the search is inaugurated, and it is for this reason that a negative finding is the usual result of bacterial examination.

Considerable interest attaches to the possibility of a diminution in the virulence of the bacillus through a sojourn in water. The scanty evidence that exists on this head indicates that some decline in virulence probably occurs. Hankin mentions that on a number of occasions he has found typhoid bacilli in waters at a time when these waters were being used for drinking, and that in several instances no cases of fever developed among the users of such water. Indeed, he specifically

takes the ground that "my finding typhoid microbes in a water supply gives no proof that the microbes were there present in a condition in which they could produce infection." Remlinger and Schneider also encountered typhoid bacilli in waters that were not giving rise to the fever and that were designated by them as being chemically "very pure." Kübler and Neufeld state that the typhoid bacillus that was first isolated by them from well water would kill a guinea-pig in a dose of one-fifth of a loop, whereas a culture isolated from the water of the same well four weeks later did not prove fatal to a guinea-pig in a dose five times as great. There thus seems to be some reason for believing that by prolonged aquatic life typhoid bacilli may be rendered innocuous or at least less virulent, even where they are enabled to survive at all. The likelihood of attenuation appears to have been singularly neglected on the experimental side and is deserving of further investigation.

PROPHYLACTIC DISINFECTANT INHALATIONS IN MEASLES AND SCARLET FEVER.

At present the chief measure for the prevention of the spread of the acute eruptive diseases is the isolation of the patient. This form of prophylaxis is based on rather rude empirical ideas. Nevertheless, this is undoubtedly a most excellent method, provided the patient can be isolated from the beginning of the disease; but this is often difficult, if not impossible. This delay leads to infection of the surroundings, and thus the value of a later isolation is materially reduced. Then, again, the prolonged isolation at present in vogue, especially in the case of scarlet fever, is, to say the least, irksome and at times seriously taxes the capacity of the hospital to care for the acute cases that stand in greater need of the advantages of hospital treatment. There is consequently great need for an efficient prophylaxis based on more rational principles than the purely empirical now in vogue. But we can not look with much hope for a rational prophylaxis so long as we are ignorant of the etiology of these diseases, and of the point or points of entrance into and departure from the body of the infecting agents as well as of the places in the infected body in which the virus accumulates and probably multiplies.

Egart,[1] in discussing this question, is inclined to assume that in measles and scarlet fever the earliest local symptoms indicate the point of localization of the specific virus, that is, at the upper end of the respiratory tract. If this be the case it should be possible by means of suitable anti-infectious agents to prevent generalization of the virus and thus lighten the attack. Furthermore, it should also be possible by such measures to prevent the development of diseases in exposed persons. On account of the lack of facilities for proper isolation, outbreaks of measles and scarlet fever were frequent in the hospital under Egart's care at Brünner. He therefore set about to introduce a method of prophylactic disinfection of the respiratory tract by means of sprays and inhalations, most of the patients being children. Non-toxic and non-irritating substances, such as limewater mixed with equal parts of water, boric acid solution of 3 per cent., trichlorid of iron solution, .05 per cent., and sodium chlorid solution, 3 per cent., were used. He used all these four solutions alternately for five minutes, twice daily. His comparative statistics appear to show that by these methods measles and scarlet fever are held in check much better than before the effort of disinfection of the respiratory tract. He believes that he is justified in ascribing to disinfecting inhalations distinct value in lessening the severity of the attack in the individual patient and in preventing attacks in exposed persons,

The method introduced by Egart is surely worthy of the consideration of physicians. It should be given further trial in hospitals for eruptive diseases so that it may be possible to form a more definite opinion as to its real value than is justifiable from the experience of a single observer. The methods advocated are certainly simple and harmless.

LATENT SYPHILIS.

There are often expressions of surprise on the part of general practitioners when the neurologists insist on the possibility of syphilis running its course in absolute latency, and without giving any manifestations by which an ordinarily careless patient would be bound to recognize it. The general rule in the development of the disease is that patients are so anxious as to the possibility of its occurrence that they actually anticipate symptoms, and some of them at least become confident that they have the disease when it does not exist. There are too many cases on record now, however, of undoubted tertiary lesions of syphilis without any history of previous stages of the disease to leave any room for doubt that the disease may, exceptionally at least, run its earlier course without attracting the patient's attention. This is all the more important, since many of the supposed nervous sequelæ of the disease are known to develop with more frequency in patients that have been insufficiently treated or that have been negligent of treatment from the beginning.

In two lectures recently delivered in London,[1] Jonathan Hutchinson, whose experience in syphilis amply justifies the acceptance of his opinion as of great value, dwells with considerable insistence on the teaching that the two earlier stages of syphilis may run a practically latent course. He emphasizes the fact that the primary sore of syphilis is not necessarily indurated in all cases, and that those who judge of it entirely by this characteristic may be deceived. As a matter of fact, the primary syphilitic lesion may be so small, so little complicated by inflammatory reaction in the surrounding tis-

1. The Clinical Journal, Aug. 5, 1903.

sues, so painless and indolent in its course as not to attract any unusual attention, especially if it should occur in the neighborhood of the nails where slight sores that run a slow course are not unusual.

Dr. Hutchinson even claims that the infection of syphilis may enter in certain cases without any breach of the cutaneous surface, and certainly without any obvious chancrous induration. He refers to instances of surgeons who have acquired the disease from a slight needle prick in operating on syphilitic patients, or in midwifery practice, without the occurrence of any local sore sufficient to arouse suspicion of its nature. As a chancre will disappear spontaneously, as a rule, in a little over four weeks, it is perfectly possible that this stage of the disease should be entirely missed. Anyone familiar with the treatment of syphilitics knows that at times the secondary symptoms are so slight and so few that they may well escape ordinary observation. It is not an unusual thing for a patient to assert positively that he has no cutaneous eruption, when the removal of his clothing discloses a blooming macular syphilid.

It is evident, then, that the possibility of latent syphilis will have to be accepted, and that certain of the nervous and other lesions which are usually connected with this disease, but which occur not infrequently in persons with regard to whom no history of syphilitic infection can be obtained, may yet be considered to be of syphilitic origin, or at least to have developed on a syphilitic basis. Visceral lesions of suspicious character occurring in individuals without a syphilitic history, must on this principle be treated first by antisyphilitic remedies, since, after all, the therapeutic test is the best possible diagnostic sign, and the therapeutics of syphilis is so hopeful as compared with any other pathologic condition as to make the trial justifiable.

ANTITYPHOID SERUM.

It is comparatively easy to immunize laboratory animals against a virulent typhoid bacillus by injecting them intraperitoneally or subcutaneously with gradually increasing doses of young, living cultures. These animals soon become resistant toward many times the minimum fatal dose of the organism, and their sera acquire high agglutinative and bacteriolytic properties. Small doses of serum of the immunized animals protect other animals against several times the minimum fatal dose of typhoid cultures, even if the serum is injected several hours after the inoculation.

Although the laboratory experiments are very encouraging, it has been found that the clinical results from these antityphoid sera are practically nil. Stokes and Fulton, for instance, immunized a hog and got very good results in laboratory animals with this serum. Half a cubic centimeter protected a guinea-pig against seven times the minimum lethal dose of a virulent culture. They treated five typhoid fever patients with this serum and noticed no special results in two. In the other three it is supposed that the serum treatment shortened the disease somewhat. Chantemesse immunized a horse with the filtered cultures and claims to have obtained slight clinical results with this serum. The unsatisfactory clinical results may be due to several causes: (1) The antisera thus far prepared may not be strong enough; (2) it is said that highly immune sera contain little or no complement, and as the human complement often disappears in the course of the disease,[1] the injection of immune bodies alone can be of no value; (3) it is also possible that the human complement does not fit into the immune bodies that have been injected.

Recently Macfadyen and Rowland[2] have obtained very encouraging results from laboratory experiments. They prepared a powerful extract of typhoid bacilli by grinding up a large quantity of organisms at a very low temperature (obtained with the aid of liquid air), and exhausting the mass thus obtained with physiologic salt solution. This extract is highly toxic for guinea-pigs, proving fatal in doses of .003 to .05 c.c. of a 10 per cent. extract. It is also toxic for monkeys. The experimenters successfully immunized a rabbit and a monkey against this extract and got agglutination of the living cultures with the serum after one injection. The animals soon tolerated larger doses, and their sera protected other animals against several times the fatal dose of the extract and of the living typhoid cultures. These sera also possess curative properties, as is shown by the fact that an animal can be saved when the serum treatment is instituted eight hours after the inoculation with living cultures.

Horses are now being immunized with this toxin, and it remains to be seen what will be the clinical results with serum thus prepared. The most interesting feature of this work is that an attempt is here made to produce an antiserum which shall be at one and the same time antitoxic and bactericidal.

THE FINANCIAL WANING OF DOWIEISM.

Dowieism has reached a crisis that may be fatal. As a religion, like its congeneric delusion, Eddyism, it has depended altogether too much on filthy lucre, and the methods of the "profit" have apparently failed to meet the requirements of honorable business. Dowie's luxurious tendencies and the late fiasco of his New York crusade have, it seems, overtaxed the resources of his credulous followers, of whom he takes such shrewd advantage. He has been the defendant in a number of suits for debt, and now a receiver has been appointed by the U. S. courts. He may weather the storm, but the probabilities are that we have seen the end of Dowie as a financier, and the end of him as a prophet is a necessary consequence. What will become of his dupes is not a pleasant thing to contemplate. Many of them, we understand, have been exhausted of all their means through his demands, and their faith will almost certainly receive a rude shock, which is likely to be more or less serious in its effects on their moral and mental future.

THE ABUSE OF HELPLESS CHILDREN IN OHIO.

A society for the prevention of cruelty to children is much needed in Ohio. In that state, human sacrifices in the name of religion are apparently authorized by law. A man allowed his 8-year-old daughter, who had been badly burned, to die without medical treatment, save that administered by Eddyites, and we know what that means. The grand jury naturally indicted the parents for manslaughter. In the trial the judge charged the jury to bring in a verdict of acquittal on the ground that no law existed in Ohio under which the parents could be prosecuted. The jury did so and the Supreme Court, to which the case was carried, ruled that the charge and the verdict were without error. It would seem that the State of Ohio is in bad shape as regards its laws protecting infant life; legislation in this regard is one of the present needs of that community.

LEGISLATION ON SANATORIUMS—PRO AND CON.

Considerable comment has been caused by the passage of an act[1] by the last New York legislature making it essential that before any hospital, camp or other establishment for the treatment of patients with pulmonary tuberculosis be established, the county board of supervisors and the town board shall both authorize such establishment and describe the limits or locality in which it may be established. This practically means a prohibition of the establishment of sanatoriums over a large section of the state, and restricts to a considerable extent the benevolent intentions of various individuals. The peculiar regulations adopted by the town of Liberty in regard to the Loomis Sanatorium are well known. All these are evidences of the irrational fears that have been excited by statements as regards the contagiousness of consumption and the dangers to the well from association with those affected by it. It is very unfortunate that the medical profession as a whole has not given out a judicial opinion on this subject or perhaps rather that so many members of it are constantly giving out injudicious statements. The public is easily misled and it takes some time for it to get its right mind in regard to questions that excite public apprehension and terror. As a contrast to this state of affairs in New York, we may notice the action of the late New Mexico legislature which offers a premium in an exemption from all taxes for sanatoriums for consumptives that may be established within a certain period and with the expenditure of a certain amount of money.[1] This, of course, is a business proposition, but it shows that the panicky fears as regards the communicability of tuberculosis have not seriously affected the legislators of New Mexico. They are willing to have consumptives come among them, and for the good of the state will take whatever risks there may be. The basis for the liberal action of the New Mexicans is not pure philanthropy, probably, but in so far as it is an index of enlightenment the "wild and woolly West" is ahead.

GERMANY'S IGNORANCE OF AMERICAN WORK.

We have on more than one occasion called attention to the persistency with which foreign investigators and writers ignore American work. The Germans have been and are, we think, the greatest offenders in this respect, and some of the most decided protests against such omissions have been made by the German-American physicians in this country. American work has been rediscovered repeatedly by Germans, and with the common reverence for the "made-in-Germany" mark, the credit has been attributed to Germans by the mass of the medical profession of the world, sometimes even after a thorough exposure of the real facts. It is a little refreshing, therefore, to read a foreign showing up of this same German ignorance of American literature. Such a satisfaction can be derived from the recent leading article in the *Semaine Medicale* (November 11), which points out that the spondylitis typhosa of Quincke, which is accepted by the Germans as a clinical discovery due to German research, was well described in all respects by an American years before Quincke's publications. Cheinisse, the author of the article, makes this very clear, and proves that Gibney pointed out the same facts and gave a correct interpretation of them ten years before Quincke's publication. Although Osler disagreed as to the spondylitic nature of the lesions which Gibney, Lovett, Withington, Cutler, Ely and others in the United States pointed out, yet the disorder is one that clearly belongs to the same category as the so-called discovery of Quincke. Cheinisse further shows that Germans also ignore the Swiss authors and refers to the work of Pallard on the same subject as evidence. Apparently, there is not a point made by Quincke and his German followers in regard to this disease that has not been previously made by American authors. Whether the Germans will at once accept this correction or not perhaps makes little difference. In the long run they will have to admit the facts. In the meantime, however, a certain amount of credit is wrongly attributed, and it is well to call attention to this state of affairs. As Cheinisse says, the saying of Solomon is still true: "There is nothing new under the sun." This especially applies to several German medical discoveries of recent years.

CIRCULATION IN THE NERVOUS SYSTEM.

At the October meeting of the New York Society for Experimental Biology and Medicine, Dr. S. J. Meltzer, the president, demonstrated some interesting specimens which seem to throw a new light on the circulation in the peripheral nervous system. His paper was on the effect of ligation on the vital staining of nerves. He demonstrated a series of pieces of dried sciatic nerves of rabbits which had received during life intravenous infusions of methylene blue. As is well known, this substance is carried all over the system by the circulation and stains all tissues, even the most delicate parts of the nerve centers, with a distinct blue tinge. By this means the course of the circulation in the nervous system and even certain peculiarities of the anatomic finer structure have been demonstrated. Dr Meltzer found that when single ligatures are applied to the trunks of sciatic nerves in animals intravenously injected with methylene blue, they are without any influence on the color of the nerve that develops after the use of methylene blue on both sides of the ligature.

1. See page 1432 of this issue.

When the sciatic nerves are ligated at two places, however, the section lying between the two ligatures remains free of color, though the central and peripheral ends of the nerves turn blue in the usual manner. This effect is produced, no matter how far apart the ligatures are applied. It is clear, then, that during life the nerve receives its circulation only from its central and peripheral ends. This seems to demonstrate how important is the influence of the circulation on the outside of the body as regards the blood supply of the nervous system. When the peripheral circulation is weak or seriously disturbed for any reason, the nerves must fail to get their due proportion of nutritious material and must serve rather to exhaust the central nervous system by draining away some of the nutritious material intended for it. This set of experiments is also wonderfully suggestive as regards the relationship of the skin and nervous systems to one another. Probably nothing that has been discovered in recent years illustrates better their interdependence.

Medical News.

CALIFORNIA.

Personal.—Dr. George S. Harkness, Stockton, whose appendix was removed November 9, is making a good recovery.——Dr. F. Henry Ottmer has succeeded Dr. O. W. Sinclair as physician-in-charge at Murray's Hospital, Eureka.

Spitting Ordinance.—The Oakland City Council has passed an ordinance prohibiting spitting on the floor or steps of any public car or conveyance, or on the floor or steps of any public building, or on any sidewalk or crosswalk, under penalty of a fine not to exceed six dollars.

Late, Yet Timely.—At a session of the California Northern District Medical Society recently held at Sacramento, where there has been a mild epidemic of smallpox, a lay journal solemnly announces the physicians "decided that the Manila itch, Cuban scratch and prairie dig, which has been afflicting the country for two or three years, and is still with us, resembles smallpox so exactly as to be smallpox, and nothing else."

More Plague.—The secretary of the State Board of Health reports a death from plague, November 6. The patient was a Chinaman, and died on the river steamer *J. D. Peters* between Bouldin Island and San Francisco.——Two deaths among Chinese women in San Francisco were reported during November. The last case was No. 109, and was reported to the San Francisco Health Office November 13. The patient died the next day.

DISTRICT OF COLUMBIA.

Personal.—Dr. William Richardson of the resident staff of St. Elizabeth's Hospital, Washington, has been appointed to a similar position at the Columbus (Ohio) State Hospital for Insane.

Kappa Psi Fraternity.—The annual convention of this society was held in Washington under the auspices of Zeta Chapter, medical department of Georgetown University, November 26 and 27. The meeting was successful, and the reports from the various chapters showed increased interest in medical fraternalism. The visiting delegates were entertained at a theater party and a banquet, which was presided over by Dr. F. H. McKeon as toastmaster. Philadelphia was chosen as the next place for meeting.

Report of Health Officer.—The report of the health officer for the week ended November 14 shows the total number of deaths to have been 121, of which number 74 were white and 47 colored. There were reported 24 new cases of typhoid fever, 10 of diphtheria, and 5 of scarlet fever. The health officer calls attention to the fact that there were reported 75 white births and 74 white deaths, 34 colored births and 47 colored deaths. There are 1,257 registered physicians in practice in the District of Columbia, while only 84 births were reported by physicians. There are 136 midwives registered and during the week only 23 reported births.

GEORGIA.

Hospital Loss Adjusted.—The loss in the recent fire at Grady Hospital, Atlanta, has been adjusted at $6,200.

Johnson Monument Unveiled.—The shaft erected in Oakland cemetery in memory of the late Dr. Walter K. Johnson, Atlanta, was unveiled November 15.

Personal.—Dr. Obadiah C. Gibson, for many years city physician of Macon, has been appointed by the State Board of Health to manage all epidemics in Bibb County.

Smallpox.—The disease is causing such alarm around Albany that the municipality has instituted compulsory vaccination. More than 200 cases exist, mostly among negroes.——Several cases are reported in Collins, Tattnall County.

ILLINOIS.

Smallpox Increases.—Smallpox has been reported in twenty counties and thirty localities. About 300 cases are said to exist at present.

Membranous Croup is Diphtheria.—In the future all cases of membranous croup in Rockford must be reported to the health officer and treated as a form of diphtheria, according to a ruling of the city health department.

Fire at Insane Hospital.—A live wire set fire to a college at the Illinois Hospital for the Incurable Insane, Bartonville, November 27. Until all danger was past Dr. George A. Zeller, the superintendent, took the 60 occupants of the cottage to the library.

Typhoid at Canton.—Canton has nearly 100 cases of typhoid fever and 5 deaths have occurred. The majority of cases are among the employes of the Parlin and Orendorff plow factory. The State Board of Health has been requested to send an official to investigate the sanitary conditions at the factory.

St. Mary's Hospital Staff.—The newly-appointed medical staff of St. Mary's Hospital, Quincy, is made up as follows: Drs. Joseph Robbins, Robert J. Christie, Sarah Vasen, John H. Rice, Henry Hatch, E. B. Montgomery, Ernest Zimmerman, William S. Knapheide, Robert J. Christie, Jr., L. H. A. Nickerson, William W. Williams, Charles E. Center and H. L. O. Whipple.

Chicago.

Bequest.—The endowment fund of St. Luke's Hospital is given $3,000 by the will of Mrs. Annie J. Tree.

More Money for Hospital.—The net proceeds of the fifth benefit concert for the Presbyterian Hospital were $8,083.

Personal.—Dr. Joseph E. Raycroft has been appointed director of the physical culture exhibit at the Louisiana Purchase Exposition.——Dr. John C. Outhet has sailed for the Orient.

City Bacteriologists' Examination.—Nine candidates for the position of superintendent of the city laboratory, vacated by the resignation of Dr. William K. Jaques, took the civil service examination November 17.

Dr. Senn's Illness.—Dr. Nicholas Senn, who was reported as seriously ill with septicemia from an infected operation wound of the right hand, has returned to Chicago and is reported much improved and progressing rapidly toward recovery.

Herzog to Manila.—Dr. Maximilian Herzog, for more than seven years professor of pathology and bacteriology in the Chicago Policlinic, has been appointed pathologist in the Bureau of the Government Laboratory, Manila, and will sail from San Francisco about December 30.

Addition to St. Luke's Hospital.—A plot of ground 40 by 161 feet, adjoining St. Luke's Hospital, has been purchased for $28,000 and will be used as a site for an addition, to cost about $300,000. It will consist of rooms and suites to be occupied by patients and possibly by their relatives, thus combining the idea of a hospital and a hotel.

Deaths of the Week.—Barely half a dozen diseases together with suicide and violence contribute 309 out of the total 512 deaths reported last week, while the same causes contributed 215 out of the total 467 reported the week before. Deaths from nervous diseases increased from 19 to 32; pneumonia from 70 to 94; and violence, including suicide, from 29 to 50. The mortality was at the annual rate of 14.15 per 1,000.

INDIANA.

Nearly Seven Thousand.—The report of the State Board of Registration will be issued in a few days. It will contain the names of nearly 7,000 physicians, 600 of whom are registered in Marion County.

Hospital Dedicated.—The Flower Mission Hospital for Incurables, Indianapolis, was formally dedicated, November 25. Morris Ross made the presentation address, and the mayor accepted the hospital on behalf of the city.

Gifts to Richmond Hospital.—William B. Leeds has given $10,000 toward the new public hospital at Richmond and Daniel G. Reid has given $50,000. The building will probably be known as the Reid Memorial Hospital. The Morrison bequest of $10,000 was turned over to the hospital trustees, November 18.

Health Officers' School.—The legislature of 1903 authorized the State Board of Health to require a certain sanitary training of health officers and also authorized the holding of a school for health officers. The health officers of the state number 516, and two schools are held annually to accommodate this number. The first school was held in June, and to it were summoned all county and city health officers. The second school, which is exclusively for town health officers, will be held December 16 and 17 at Indianapolis. Among the teachers for this school are ex-Surgeon-General George M. Sternberg, U. S. Army; Surgeon-General Walter Wyman, U. S. P. H. and M.-H. Service; Dr. Frank G. Novy, University of Michigan; Dr. Charles O. Probst, secretary American Public Health Association and secretary Ohio State Board of Health; Dr. Frank Allport, Chicago; Prof. David Dennis of Earlham College and Prof. Coulter and Prof. Burrage of Purdue University. The lectures will all relate to subjects pertaining to the practical application of disease-prevention measures. The Hon. William L. Taylor, ex-attorney-general, who has written and revised the health and medical laws of the state, will expound the state and national laws relating to public health and quarantine.

Sickness and Death in October.—The health in October, 1903, was not as good as in the same month last year. It was better, however, as compared with September. Typhoid fever is reported as being the most prevalent disease, 78 counties reporting the disease present, deaths being reported from 64 counties. It was also the most prevalent malady last month. Rheumatism was reported as second in area of prevalence, while diarrhea occupied this position last month, but it has fallen this month to seventh place. The order of prevalence was: Typhoid fever, rheumatism, intermittent fever, bronchitis, tonsillitis, scarlet fever, diarrhea, diphtheria, pneumonia, influenza, pleuritis, erysipelas, measles, dysentery, cholera morbus, inflammation of bowels, whooping cough, cholera infantum and cerebrospinal meningitis. During the month 324 cases and 1 death from smallpox in 38 counties were reported. This is a decided increase in the number of cases and area as compared with the preceding month, but a decrease as far as deaths are concerned. In the corresponding month last year 298 cases were reported, with 19 deaths in 35 counties. We have, therefore, to record an increase so far as cases and area covered is concerned, but a decided decrease in deaths. The total number of deaths from all causes reported was 2,572, a rate of 12 per 1,000 per annum. The city death rate was 15.4 and the country death rate was 10.3. Tuberculosis claimed 256 victims; 160 typhoid deaths were reported; diphtheria caused 63 deaths; pneumonia deaths numbered 132; influenza, 8; cerebrospinal meningitis, 25; puerperal septicemia, 10; cancer, 105; and violence, 146.

IOWA.

Smallpox at Corning.—It is reported that there are twenty cases of smallpox at Corning and that schools and churches are to be closed.

Acquitted.—Dr. B. A. Wilder, Sibley, charged with having caused the death of Anna Gedneka by a criminal operation, was found not guilty November 9.

New College Building Dedicated.—The new medical college building of Drake University, Des Moines, was formally dedicated December 3. The building has been completed and in use by the students for some time.

License Revoked.—The State Board of Medical Examiners, on November 14, considered the case of Dr. R. A. Snook of Sandyville, Warren County, who plead guilty of immorality. He promised not to offend in future, but the board decided not to accept his offer of reformation and his license was revoked.

MAINE.

Bangor Personal.—Dr. Galen M. Woodcock has resigned as member of the board of health.——Dr. George L. Hilton has been elected city physician, vice Dr. Edson E. Goodrich.

Smallpox.—Keeneville has been found to be the center of a fresh outbreak. Cases were discovered in Skowhegan and traced to Keeneville, where several families were found to be infected.——Fifty cases of a mild type are reported in Bangor. General vaccination has been ordered, but neither schools nor public places have been ordered closed.

"Holy Ghosters" Quarantined.—The State Board of Health has put the Bible School of the Holy Ghost and Us Society under strict quarantine. So many cases of smallpox have developed there that it has been made the pesthouse for the surrounding country. These "Sanfordites" protest against any medicinal aid, and through their belief that the Lord will heal, have been the means of disseminating the disease widely in that region.

MARYLAND.

Baltimore Personal.—Dr. N. G. Keirle, Jr., left London last week for Paris to study at the Pasteur Institute. On his return he will be assistant of the Pasteur department at the City Hospital, which is under the charge of his father.

Deaths in Baltimore.—For the week ended November 28, 177 deaths and 79 births were reported. The annual death rate was 16.50 per 1,000. Among the causes of death were consumption, 23; Bright's disease, 21; pneumonia, 14; cancer, 6, and typhoid fever, 5.

Section Officers Elected.—At the inaugural meeting of the section on ophthalmology, otology and laryngology of the Medical and Chirurgical Faculty of Maryland for 1903-4, held November 27, at Baltimore, Dr. Harry Friedenwald was elected chairman, and Dr. James J. Carroll, secretary-treasurer.

House Staff Appointed.—The following have been appointed house staff of the Frederick County Emergency Hospital recently established at Frederick by the county medical society: Drs. Franklin B. Smith, William C. Johnson, Henry P. Fahrney, Ira J. McCurdy, Samuel T. Haffner, Wilson A. Long and Harvey Getzendanner.

Charges Dismissed.—The county commissioners of Baltimore county dismissed the charges against Dr. John C. Schofield, health officer of the Twelfth District, preferred against him by Dr. John S. Fulton, secretary of the State Board of Health. It was alleged that Dr. Schofield neglected his duty in allowing suspects to escape from the camp of detention at Hombergville during the late smallpox epidemic, and had not reported deaths at Bayview Asylum in the proper form to the health office in Baltimore.

NEW YORK.

Diphtheria in Auburn Abating.—The epidemic of diphtheria in the western portion of Auburn is abating, and schools were reopened this week.

Convicted of Attempted Abortion.—Dr. Henry C. Chapin, Findley Lake, was convicted, November 22, of attempted abortion. This is a compromise verdict, as he was charged with manslaughter in the first degree.

Smallpox at Corinth.—Dr. Frederick C. Curtis, Albany, medical officer of the State Department of Health, reports that he found several mild cases of smallpox at Corinth, Saratoga County, and that all are properly quarantined.

New York City.

Nurses of St. Luke's Hospital.—The Alumnæ Association of this hospital has realized about $4,000 from a fair to endow a room for the use of the nurses when sick.

Fewer Deaths from Tuberculosis.—According to a circular just issued by the health department the death rate from pulmonary tuberculosis in New York City has fallen from 4.2 per 1,000 in 1881 to 2.29, or a reduction of more than 40 per cent.

Personal.—Dr. John W. S. Gouley is giving a course of lectures on Wednesday evenings at Bellevue Hospital on "The Principles of Conduct Adapted to Medical Students and Physicians."——Dr. and Mrs. William T. Bull have sailed for Europe.

Family Exterminated by Pneumonia.—It is reported that a whole family has been wiped out by the ravages of pneumonia. The disease first attacked a young girl, who died in St. Peter's Hospital. Her father, mother, sister and uncle called at the hospital to see her, and all of them, as well as a brother, died of the same disease within a few days.

Abortionist Arrested.—Through the combined efforts of the New York County Medical Society, the health commissioner and the Society for the Prevention of Cruelty to Children, Dr. Francis Gray Blinn was arrested in his own sanitarium, charged

with attempting to perform an illegal operation. A medical student named Edwin Watkins, impersonating "Dr. J. Sterling Loomis" of Bayonne, took a prominent part in the procedures leading to this arrest. Dr. Blinn agreed to pay "Dr. Loomis" a commission of $100, the fee asked for the operation being $500. Dr. Blinn was arrested in January, 1893, and in March, 1902, on similar charges, but was discharged for lack of evidence. He has now fled from the city, forfeiting his bail of $1,000.

OHIO.

Sisters' Hospital Soon to Open.—The building at Clifton which the Sisters of Charity have remodeled and equipped as a hospital, is now almost ready to receive patients.

Medical Libraries Consolidated.—The books formerly in the medical department of the Cincinnati Public Library have been removed to the City Hospital, and, with the library already accumulated there, will make a large and useful library.

Personal.—Dr. Charles H. Willgohs, Akron, celebrated his centenary on November 20.——Dr. Dudley P. Allen, Cleveland, gave a dinner, November 21, in honor of Dr. William Mayo, Rochester, Minn.——Dr. Adam H. McCullough has been inducted into the office of health officer of Mansfield, vice Dr. J. Harvey Craig.——Dr. Walter W. Brand was re-elected health officer of Toledo, November 24.

Epidemics.—MEASLES at Columbus Barracks, 22 cases; SCARLET FEVER at the Institution for the Blind, Columbus, 25 or more cases; at Bowling Green and at McArthur the public schools have been closed; SMALLPOX, 13 cases at Steubenville, 40 cases at Cambridge, 3 cases at Washingtonville, schools and churches closed; Marysville has quarantined against Union County and has prohibited public gatherings; Youngstown has 21 cases.

PENNSYLVANIA.

Trained Nurse Convicted.—Daisy Goeing, a trained nurse, was recently sentenced to five years' imprisonment on pleas of guilty to robbing the safe of the West Philadelphia Hospital for Women, and obtaining goods by false pretenses.

The Typhoid Situation at Butler.—On November 28 the State Board of Health held an adjourned session in Butler, Pa., to investigate the cause of an epidemic of typhoid fever at that place, which has affected more than 1,200 people. The cause is charged to polluted water furnished by the Butler Water Company. It is claimed that because of the loss of a dam the company for a time pumped water directly from a creek when there were many typhoid cases on the tributaries of the stream. Because of the epidemic many families are in destitute circumstances, and a public meeting has been held to raise a fund to support emergency hospitals and to aid other relief work. Later information has been received to the effect that diphtheria has made its appearance among the fever-stricken children in St. Paul's Orphan Home. A physician and four nurses have been detailed for the institution and strict quarantine has been established. So far 3 cases have been discovered. Six physicians and more than 50 nurses have come to Butler to aid in care of the sick. Twenty-five new cases of typhoid fever were reported December 1, with 4 deaths.

State Board Meets.—The State Board of Health met in Pittsburg, November 27. Dr. Benjamin Lee, secretary, in his annual report gave particular attention to the status of smallpox in Pennsylvania. During the year ending November 1 there were 6,504 cases of smallpox and 503 deaths from the disease. The largest number occurred in Pittsburg, where there were 1,234 cases and 238 deaths. In Philadelphia, up to October 1, there have been 948 cases and 138 deaths. A careful calculation leads to the conclusion that outside of the large cities about 1,500,000 school-days were lost because of the disease, while the inclusion of the large cities would swell the figures enormously. In Philadelphia, for example, seven elementary schools, with an enrollment of more than 5,000 pupils, were closed in a single day. The report deals also with measures taken to prevent the pollution of streams, tuberculosis, tetanus and proposed legislation to stop the sale of toy pistols and dangerous explosives. Chairmen of the standing committees are as follows: Charles H. Harvey, Philadelphia, executive; Benjamin Lee, Philadelphia, registration and vital statistics; George G. Graff, Bucknell College, preventable diseases; A. M. Embrick, Boiling Springs, adulteration, etc.; John Fulton, Johnstown, water supply and sanitation; Samuel T. Davis, Lancaster, public institutions and school hygiene; H. J. McClelland, Pittsburg, sanitary legislation.

Philadelphia.

The Muetter lecture on surgical pathology, College of Physicians for 1903, was delivered in the lecture hall of the college, December 1, by Dr. Charles N. B. Camac of Cornell University, New York City, the subject being "Some Observations on Aneurism and Arteriosclerosis."

Smallpox and Deaths.—For the week ended November 28, new smallpox cases were reported from 26 of the 42 wards of the city. There was a total of 70 new cases with 11 deaths. Deaths from all causes numbered 495, compared with 409 the week before and 454 for the corresponding period of last year.

Dispensary Burns.—On the evening of November 29 a building used by the Children's Homeopathic Hospital for dispensary purposes and for sleeping apartments for servants was destroyed by fire, involving a loss of some $4,000. A threatened panic of the inmates was prevented by the prompt and cool action of the nurses.

City Not Responsible.—A man recently brought suit against the city to recover damages because of the illness of members of his family asserting that they had contracted typhoid fever as a result of foul gases arising from garbage. Attempt was made to hold the city responsible for the deposit of this noxious matter. The plaintiff lost the suit, the defense producing expert testimony to prove that typhoid germs can not be introduced into the system by breathing impure air.

RHODE ISLAND.

Typhoid at Brown.—Brown University, Providence, is having a small epidemic of typhoid fever. Nine cases have so far developed, but the source of infection has not been discovered.

Personal.—Dr. Craig Cameron, Olneyville, was seriously burned about the face by carbolic acid.——Dr. Lucius F. C. Garvin, Lonsdale, has been re-elected governor of the state by 5,000 plurality.

Verdict Against Physician.—A Providence jury has given a verdict for $2,375 against Dr. J. Leroy Fisher of that city in favor of a boy whom he treated for a fracture of the leg, which the complainant claimed was not properly treated, as ulceration and shortening followed.

Vanderbilt Donation to Hospital.—Mrs. Cornelius Vanderbilt, Sr., has transferred to the trustees of the Newport Hospital the memorial edifice to her husband which she has erected and equipped on the grounds of the institution, at a cost of $250,000. It is to be known as the Cornelius Vanderbilt Pavilion.

TEXAS.

Quarantine Raised.—The quarantine maintained by Denison and McKinney against Sherman, on account of smallpox in the latter city, has been raised on the advice of the state health officer.

Increases Scope and Stock.—Dallas Medical College has filed an amendment to its charter, adding to its purpose clause the right to maintain a medical dispensary, and also increasing its capital stock from $3,000 to $6,000.

State Health Officer Supreme.—The attorney general has rendered an opinion that all county and city quarantine authorities are subordinate to the state health officer and that health certificates issued by him must be respected by local authorities.

Laredo Fever-free.—Laredo has had no case of yellow fever since November 25, and should this favorable condition continue, the health authorities will soon give the city a clean bill of health and raise the quarantine. The total cases have numbered 1,022, with 99 deaths, a mortality of 9.7 per cent.

To Decrease Degeneracy.—Dr. Marvin L. Grayes, San Antonio, superintendent of the Southwestern Insane Asylum, in his annual report says there are 3,200 insane persons in asylums and 2,000 at large in Texas. He believes the time is near when some humane means, surgical or otherwise, will be demanded to prevent the continuation of a race of degenerates and dependents.

FOREIGN.

Santiago, Chili, Sewer System.—The government of Chili has provided for the appropriation of $5,000,000 to establish a drainage and sewage system in the city of Santiago.

Sleeping Sickness at Paris.—The three negroes from the Congo exhibited at the Paris Académie de Médecine, as mentioned on page 1335, are attracting much interest. They spend most of their time in bed, but do not suffer at all, and are confident that they will soon be cured. Each has a remarkable appetite and digestion is good. The Association des Dames Françaises has placed its small hospital at the service of the Institute of Colonial Medicine, and the negroes are cheerful in their new surroundings.

Italian Regulations for Notification of Disease.—The Italian government has recently ordered that when the authorities are notified in regard to the presence of a case of contagious disease in a house the notice must state whether the patient is attending school and mention the school and also whether there are other school children in the family or house or persons employed in a school. The local authorities will then notify the principal of the school mentioned so that he will debar persons from the infected home in case they come to school. Another regulation is to the effect that children with chronic affections such as trachoma, impetigo, tinea and tuberculous affections of the skin or bones, may attend school, but must sit apart from the other children, without any possible contact between them and their mates. Children with suppurating tuberculous lesions of the skin, bones or glands, are also allowed to attend school if their lesions are kept covered and if they are seated at isolated desks.

Marmorek's Antituberculosis Serum.—Dr. Marmorek has long been connected with the Pasteur Institute at Paris as chief of the chemical laboratory. During the past year he has been experimenting with an antituberculosis serum whose effects on lower animals have been so good that he is encouraged to propose it for the treatment of humans. The other scientists connected with the institute refused to sanction its publication at this early date and wished to wait for further experience. Marmorek has consequently withdrawn from the Pasteur Institute, and read a communication before the Académie de Médecine, November 17, describing his technic and results to date. The *Bulletin* for that meeting has not yet been received. His communication had been announced for November 10, but Roux of the Pasteur Institute secured its withdrawal. On deliberation, however, the Académie gave audience to Marmorek at the following meeting. Roux stated that the results of control tests at the Pasteur Institute were entirely opposite to those which Marmorek asserts to have obtained. A cable dispatch from Paris in the daily press December 2, announces that Prof. G. Dieulafoy reported to the Académie that he had tested the Marmorek serum on seven patients, Marmorek operating. Instead of becoming better, he says, they became worse and five died. Le Dentu made a similar report.

Tuberculosis Conference at Berlin.—The physicians in charge of the tuberculosis sanatoriums in Germany meet annually at Berlin to discuss matters connected with their specialty. This year all medical men officially engaged in the campaign against tuberculosis were invited to the meeting, which was, therefore, an exceptionally interesting one. B. Fraenkel, in his opening address, considered it necessary to defend the sanatoriums against certain aspersions. He stated that the influence of climate is not important as more than 30 per cent. of the patients treated in sanatoriums at the ordinary altitude have had their working capacity restored for more than four years. He referred to immunization against tuberculosis as a dream for the future without practical value for the present, and offering no prospects as yet of rendering the sanatoriums superfluous. Their value as a means of educating the people in the prophylaxis of tuberculosis can not be overestimated. Treatment with tuberculin was discussed at great length, the general opinion seeming to be growing more and more favorable to it, especially for tuberculosis in children. Sanatorium treatment for tuberculous children was qualified as indispensable and blessed in its results. Children need especial care when they are leaving school to enter apprenticeships, also during convalescence from infectious diseases. Heubner made an impassioned appeal for more convalescent homes and sanatoriums for children, and it was decided after long discussion that the expense of such institutions ought to be borne by the community or group of communities. Brandenburg already has organized an association for the purpose. Germany also has one or two sanatoriums for tuberculous children, recently opened, and the gain in weight of all the children has been remarkable. One of the sickness insurance societies has opened a home at Berlin for incurable consumptives, with accommodations for 20. It is designed for those whose home environment favors contagion of others. The inmates are allowed to see their friends every day at certain hours, and are given leave of absence for half a day twice a week. Only 8 of the 35 taken in have died; 2 others have left to resume work.

LONDON LETTER.

The Etiology of Sleeping Sickness.

We have recently referred to the "progress report" of the commission appointed by the Royal Society to investigate sleeping sickness (The Journal, October 10, p. 918). Their provisional conclusion—that sleeping sickness is caused by the entrance into the blood and thence into the cerebrospinal fluid of a species of trypanosoma which is transmitted from the sick to the healthy by a species of tsetse fly—is now fully borne out by the complete report and constitutes a discovery which ranks with those of the mosquito origin of malaria and yellow fever. Some conception of the ravages wrought by this disease among the native population in Uganda may be formed from the condition of the Buvuma Island, where a population of 22,000 has been reduced to 8,000 since the outbreak of the disease, while the province of Busoga has been almost depopulated in the southern parts. Colonel Bruce was dispatched by the government to superintend a further investigation into this disease, on which some work had already been done by the previous commission sent out by the Royal Society. He was accompanied by Dr. Nabarro as bacteriologist, and while in Uganda was joined by Captain Grieg, I. M. S., who had been sent out by the Indian Government to study the disease. Colonel Bruce and his party reached Entebbe on March 16, and found that Dr. Castellani, a member of the previous commission who had remained at work on the investigation, had observed in 5 cases of sleeping sickness trypanosomes in the cerebrospinal fluid, and in one case in the blood. At that time Dr. Castellani did not consider that this parasite had any causal relationship to the disease. As soon as it was reported to Colonel Bruce, whose investigations into the tsetse fly disease in South Africa are well known, the whole party, with the assistance of Dr. Moffat, the principal medical officer, and his assistant medical officer, addressed themselves with ardor to this line of investigation with the result that by the first week in April, out of 34 cases of sickness examined, 70 per cent. were found to have this parasite in the cerebrospinal fluid, whereas control cases of patients under treatment for other diseases in the native hospital, when examined in the same way, showed no trypanosomes in their cerebrospinal fluid. The further progress of the investigation increased this proportion to 100 per cent. of cases examined, in all of which the parasite was found not only in the cerebrospinal fluid, but also in the circulating blood. A series of experiments was carried out in which it was discovered that monkeys inoculated with cerebrospinal fluid from sleeping sickness patients, or with blood from natives not as yet showing symptoms of sleeping sickness, but containing a similar parasite, sickened and died, with all the symptoms of sleeping sickness. From the analogy of the closely related disease in cattle, the nagana or tsetse fly disease of South Africa, it was suspected that in sleeping sickness a like method of infection took place. Along the lake shore numbers of tsetse fly (*Glossina palpalis*) were found, and it was demonstrated by experiment that not only were these flies, fed on sleeping sickness cases, capable of conveying the disease to healthy monkeys, but that the freshly-caught flies from an infected area, without any artificial feeding, were also capable of conveying the disease. It was further discovered that this fly, like its congener the tsetse fly of South Africa, is confined to well-defined areas, which correspond absolutely with the distribution of sleeping sickness, whereas, in regions where no *Glossina palpalis* is found, although other biting flies abound, there is no sleeping sickness. Moreover, a large percentage of the inhabitants of the sleeping sickness areas have in their blood the trypanosoma, but in not a single case taken from inhabitants of non-sleeping sickness areas was this parasite found.

Correspondence.

American and International Congresses on Tuberculosis and Tuberculosis Exhibits for the Years 1904 and 1905.

New York, Nov. 27, 1903.

To the Editor:—During the past few months I have received many inquiries concerning the various tuberculosis congresses (American and international) which have been projected for the years 1904-5. The multiplicity of these various congresses and the similarity of their names lead naturally to great confusion.

It is announced that a congress on tuberculosis is to be held in St. Louis in October, 1904, under the name of "International Congress on Tuberculosis." On careful inquiry I learned the following facts about this congress: Mr. Francis, the president of the St. Louis Exhibition, has been approached by the officers of the "American Congress on Tuberculosis,"

which was founded some years ago by Clark Bell, a lawyer of the city of New York, to sanction the holding of an international congress on tuberculosis in connection with the Louisiana Purchase Exposition. From a letter received from Dr. E. J. Barrick of Toronto, Canada, the president of this congress, I learn that Mr. Francis has appointed the above-mentioned Mr. Clark Bell chairman of the committeé on organization. Mr. Clark Bell is also the treasurer and chairman of the executive committee of the "American Congress on Tuberculosis," season 1903-1904; a Mr. Samuel Bell Thomas of 290 Broadway, New York, is the secretary of the latter. The officers of the international congress are not yet elected. I was desirous to learn the names of other medical men interested in this congress, and Dr. Barrick very kindly wrote me November 16, that he had asked Mr. Bell to furnish me the desired additional information, but nothing has thus far been received.

The other international tuberculosis congress announced is the one to meet in Washington, D. C., April, 1905. It is to be held under the auspices of "The American Congress on Tuberculosis for the Prevention of Consumption," of which Dr. Daniel Lewis, New York, is president, and Dr. George Brown, Atlanta, Ga., is secretary.

I want to call attention to the difference in name of the two American congresses, one is "American Congress on Tuberculosis," the other "The American Congress on Tuberculosis for the Prevention of Consumption."

The congress which was to meet under the name of "Congrès International de la Tuberculose" at Paris from Sept. 26 to Oct. 1, 1904, has been recently postponed to the year 1905. The president of this congress is Professor Brouardel, honorary dean of the Faculty of Medicine of Paris. The general secretary is Dr. M. Letulle, professor agrégé of the Faculty of Medicine, residing at 7 rue Magdebourg, Paris.

There will be held during the coming year independently of the above-mentioned congresses two tuberculosis exhibitions, one in Baltimore, and the other in St. Louis. The Baltimore Tuberculosis Exhibition will be held in January, 1904, under the combined auspices of the tuberculosis commission, the Maryland Board of Health, and the Maryland Public Health Association.

The other tuberculosis exhibition will be held in St. Louis, in connection with the Exhibition of Social Economy and under the subsection of hygiene, of which Dr. J. N. Hurty of Indianapolis is superintendent.

All indications point toward success of both exhibits, and it is to be hoped that they will fulfill their high purpose and at the same time be a credit to American physicians and hygienists.

Considering the various congresses I do not hesitate to express a feeling of deep anxiety. The first one mentioned, which for reason of brevity I will call "The Bell Congress," because it owes its inception to Mr. Clark Bell, has, to my knowledge, not the support of our best men. The second congress in point of time, which again, for the sake of brevity and clearness, I may call "The Lewis-Brown Congress" (names of the president and secretary), while it has many distinguished men of various state and provincial boards of health among the members, has, like the Bell congress, thus far not among them the men we are wont to look up to as leaders in movements of this kind.

What are our confrères across the water to think if they hear of two American congresses on tuberculosis and each having an international one under its auspices? The European authorities found it best, instead of having a triennial congress, to have one more year to intervene. This will make the congress in Washington and the one in Paris convene in the same year (1905).

If President Francis of the St. Louis Exposition desires that a tuberculosis congress shall be held in St. Louis, let him call to his aid some of the men who are recognized as leaders in our profession. They will counsel with him on the advisability of such a congress, and if it is decided that one should be held, Mr. Francis can be assured that the best element of Europe and America will come to St. Louis to contribute to its success.

The officers and members of the Lewis-Brown congress must realize that they can not expect to have their international meeting in Washington to be successful, when, six months later, there will be an international congress in Paris. I hope that there will be enough patriotism and national pride for all interested to realize that two American congresses on tuberculosis is an anomaly, and that, if the St. Louis congress is to be a success, it must be in the hands of medical men well and favorably known in this country and abroad.

As a solution of the problem I beg leave to suggest the following: During the Tuberculosis Exposition in Baltimore next January all interested should meet on a certain date on this neutral ground for the purpose of coming to an agreement about a single representative national or international tuberculosis congress to be held in America. There, too, should be formed a national committee on tuberculosis which is to be in touch with the international tuberculosis congress which will convene in Paris in 1905.

S. A. KNOPF, M.D.

16 West Ninety-fifth Street.

Mercuric Cataphoresis.

PHILADELPHIA, Nov. 25, 1903.

To the Editor:—I wish to correct a mistake which I allowed to remain when correcting the report of my remarks on the papers of Drs. Dunning and Bovée. This discussion appeared in THE JOURNAL, November 14, page 1194. I was reported as speaking of a method of diffusion of mercury through the "abdominal wall" for chronic inflammation of the uterine appendages. It should have been "vaginal wall." The method referred to is described in a paper in THE JOURNAL, Aug. 30, 1902, and I will be glad to send reprints to those who wish them.

G. BETTON MASSEY.

Marriages.

EMMETT M. HARRISON, M.D., to Miss Salome Bradley, both of Knoxville, Tenn., September 7.

ARTHUR GILBERT BARRETT, M.D., to Miss Alice Hollander, both of Baltimore, November 18.

OMAR H. REES, M.D., Ogden, Ill., to Miss Lydia Matilda Georg of Indianapolis, November 11.

FRANK H. THOMAS, M.D., Valdosta, Ga., to Miss Ann E. McKay of Riverton, Va., November 18.

SAMUEL H. NEAL, M.D., Elkhorn, W. Va., to Miss Bertha M. Jones of Philadelphia, November 18.

JAMES MORRISON BODINE, M.D., to Mrs. Laura M. Williams, both of Louisville, Ky., November 25.

JULIA SEATON KAPP, M.D., Denver, Colo., to Frank W. Sears of Lynn, Mass., at Boston, November 15.

FRANK CLINE FERGUSON, M.D., Spartansburg, S. C., to Miss Edith Seward, at Baltimore, November 18.

EDWIN ELLIOTT ARMSTRONG, M.D., Sylvania, Ohio, to Miss Myrtle Demuth of Toledo, Ohio, October 21.

JAMES R. RICHARDS, M.D., Thermopolis, Wyo., to Miss Edith M. Blatchford of Terry, S. D., November 14.

ROBERT A. MARTIN, M.D., Pell City, Ala., to Miss Mary Lee Campbell of Birmingham, Ala., November 18.

GEORGE C. MOREY, M.D., Remsen, N. Y., to Miss Edna Richards of Steuben, N. Y., at Remsen, November 10.

GEORGE LAWRENCE STEVENSON, M.D., Sacramento, Cal., to Miss Frances Burt of San Francisco, November 14.

JESSE NEWMAN REEVE, M.D., Washington, D. C., to Miss Ashley Macon Miller of Richmond, Va., November 17.

THEOPHILUS LACY MASTIN, M.D., Huntsville, Ala., to Miss Mary Cyrene Burch, at her home near Versailles, Ky., November 17.

Deaths.

Horace C. White, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1859, one of the most prominent physicians of Somerville, Mass.; assistant surgeon of the Eighth Maine Volunteer Infantry during the Civil War; a member of the American Medical Association, Massachusetts Medical Society,

Maine Medical Association, ninth International Medical Congress, and sometime president of the Boston Gynecological Society, and the Somerville Medical Society, for two terms a member of the state legislature and a trustee of the Somerville Hospital since its organization, died at his home, November 26, after a long illness, from heart disease, aged 67.

Henry Eugene Winslow, M.D. College of Physicians and Surgeons, New York, 1894, surgeon U. S. Constabulary in the Philippine Islands, formerly of West Oakland, Cal., at one time medical inspector of the Manila Board of Health, and a medical officer of great promise, died from amebic dysentery in the Civil Hospital, Manila, October 8. The council of the Manila Medical Society, at a meeting held October 10, adopted resolutions eulogistic of the ability, modesty and simplicity of the deceased officer and deploring his untimely death.

Hawkins Brown, M.D. University of Louisville, 1854, a venerable and honored practitioner of Kentucky; once president of the Kentucky State Medical Society; a member of the American Medical Association, died at his home in Hustonville, December 1, aged 73. He was surgeon of the First Kentucky Cavalry, and served on General Stoneman's staff during the Civil War.

Charles Schaeffer, M.D. University of Pennsylvania, Philadelphia, 1859, the well-known scientist, and member of many learned societies, who devoted himself especially to botany, died at his home in Philadelphia, November 23, from heart disease, aged 65. He was in active practice until 1898.

Frank L. Swallow, M.D. University of Pennsylvania, Philadelphia, 1900, of Pittsburg, Pa., died suddenly, November 17, at Manor, Pa., whence he was to be taken to the West Penn Hospital to be treated for neurasthenia, aged 27.

Allen Hazen, M.D. College of Physicians and Surgeons, New York, 1895, of New York City, a member of the Society of Alumni of the City Hospital, died at Jericho Center, Vt., November 17, after an operation for appendicitis.

John W. Van Osdol, M.D. Miami Medical College, Cincinnati, 1879, of Dillsborough, Ind., died at the home of his son in Rushville, Ind., November 2, from paralysis, after an illness of 11 days, aged 58.

Charles A. H. De Szigethy, M.D. University of Giessen, Germany, 1867, a member of the American Medical Association, died at his home in Brooklyn, November 17, from heart disease, aged 65.

Theodore A. Trulson, M.D. College of Physicians and Surgeons of Chicago, 1885, died from paralysis of the heart following diphtheria, November 18, after an illness of thirteen days, aged 42.

Carrie L. Heald, M.D. Northwestern University Woman's Medical School, Chicago, 1897, died at her home in Osceola, Neb., November 18, from typhoid fever, after an illness of four weeks.

William Hutton, M.D. University of Michigan, Ann Arbor, 1874, was drowned November 22, by breaking through the ice while crossing Apple River at his home in Elizabeth, Ill., aged 58.

Louis H. Dravo, M.D. Jefferson Medical College, Philadelphia, 1881, who had suffered from asthma for several years, was found dead at his home in Pittsburg, November 18, aged 50.

Samuel Talmage, M.D. New York University, 1870, a member of the Kings County (N. Y.) Medical Society, died at his home in Brooklyn, November 20, from paralysis, aged 72.

Thomas A. Barr, M.D. Eclectic Medical Institute, Cincinnati, 1864, died at his home in Lebanon, Mo., November 15, after a lingering illness, from Bright's disease, aged 62.

Alphonse J. Mervy, M.D. Cooper Medical College, San Francisco, 1876, of San Francisco, died at San Diego, Cal., November 17, after an illness of three months, aged 56.

Benjamin F. Sippy, M.D. St. Louis College of Physicians and Surgeons, 1884, died at his home in Belle Plaine, Kan., November 19, from cancer of the stomach, aged 55.

John Tascher, M.D. Eclectic Medical Institute, Cincinnati, 1878, formerly of Chicago, died at Albuquerque, N. M., November 16, from nephritis, after a long illness.

Henry T. Templeton, M.D. Medical College of Georgia, Augusta, 1867, died suddenly at his home in Laurens, S. C., November 10, from heart disease, aged 62.

Raymond P. Eddy, M.D. Eclectic Medical Institute, Cincinnati, 1860, died at his home in Providence, R. I., November 11, after an illness of about one year, aged 80.

Douglas W. Tice, M.D. St. Louis Medical College, 1860, a practitioner in Troy, Mo., for more than 40 years, died at his home in St. Louis, November 11, aged 70.

B. Brown Henry, M.D. University College of Medicine, Richmond, 1900, of West Newton, Pa., was struck by a train at that place, November 17, and instantly killed.

James G. Dickson, M.D. Jefferson Medical College, Philadelphia, 1851, died suddenly from heart disease at his home in Canonsburg, Pa. November 14, aged 78.

Jefferson K. Heltman, M.D. Medical College of Indiana, Indianapolis, 1875, died suddenly from heart disease, November 8, at his home in Oaklandon, Ohio.

Herbert A. Starkey, M.D. Medico-Chirurgical College of Philadelphia, 1889, died suddenly at his home in Kingston, N. Y., November 21, aged 35.

Willard L. Collins, M.D. Western Pennsylvania Medical College, Pittsburg, 1892, died suddenly at his home in Girardville, Pa., November 2, aged 38.

T. Clayton Williams, M.D. University of Maryland, Baltimore, 1868, died at Winchester, Va., October 29, from acute Bright's disease, aged 59.

John L. Watkins, M.D., assistant surgeon in the Confederate Army during the Civil War, died at his home in Milton, N. C., October 24.

Matthew A. Schweeters, M.D. Western Reserve University, Cleveland, 1890, died suddenly from heart diseases at his home in Leesville, Ohio.

John A. Hickman, M.D., surgeon in the Confederate service, died at his home in Cynthiana, Ky., November 18, after a short illness, aged 76.

Daniel J. Turner, M.D. University of Maryland, Baltimore, 1894, died at his home in Front Royal, Va., November 10, aged 38.

Thomas J. West, M.D. Charity Hospital Medical College, Cleveland, 1868, died at his home in Tiffin, Ohio, November 18, aged 68.

Zera W. Monroe, M.D. Rush Medical College, Chicago, 1890, died at his home in Monroe, Wis., November 20, from tuberculosis.

Edward E. Smart, M.D. Tulane University, New Orleans, 1856, died recently at his home in Leesville, La.

William Joseph von Mitden Einerhand, M.D., died November 10 at his home in Newport, Ky., aged 81.

Orion M. Cox, M.D., died from pneumonia at his home in Cox's Creek, Ky., November 21, aged 74.

L. F. Watson, M.D., died at an advanced age at his home in Springfield, Mo., November 18.

Book Notices.

PRACTICAL GYNECOLOGY. A Comprehensive Text-Book for Students and Physicians. By E. E. Montgomery, M.D., LL.D., Professor of Gynecology, Jefferson Medical College. Second Revised Edition. With 539 Illustrations, the Greater Number of Which Have Been Drawn and Engraved Especially for This Work, for the Most Part from Original Sources. Cloth. Pp. 900. Price, $5.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

While it is only three years since the first edition of this book was issued the author has found it necessary to revise many parts so as to bring it well up to date, and to include all the later important operative procedures. Several changes have been made in the arrangement. In our review of the book on its first appearance we criticised the classifying of the various lacerations of the pelvic floor, vaginal fistula, etc., under malformations; in this edition these and similar conditions are grouped under a new general division of traumatisms. Other minor changes are also to be observed, all bettering the book. Many new illustrations have been added, and not a few of the old ones have been redrawn. The book is unusually well gotten up and the binding has been especially improved. As we said in noticing the work on its first appearance, the author is neither too radical nor too conservative in the consideration of the conditions that may need radical operations. In the introduction he tells us that the true gynecologist must be "so conservative that he will sacrifice no organ whose physiologic integrity is capable of being restored; so bold and courageous that his patient shall not forfeit her opportunity for life or restored health through his failure to assume the

responsibility of any operative procedure necessary to secure the object." This is the basal idea that permeates the book; the ultraradical operator will find no endorsement, and the "tinkering" gynecologist—he who treats all diseases of women by means of a pledget of cotton and a speculum—no encouragement in its pages. The book is one that we can recommend to the student, to the general practitioner—who must sometimes be a gynecologist to a certain extent whether he will or not—and to the specialist, as an ideal and in every way complete work—a practical work for practical workers.

A DICTIONARY OF MEDICAL SCIENCE. Containing a Full Explanation of the Various Subjects and Terms of Anatomy, Physiology, Medical Chemistry, Pharmacy, Pharmacology, Therapeutics, Medicine, Hygiene, Dietetics, Pathology, Bacteriology, Surgery, Ophthalmology, Otology, Laryngology, Dermatology, Gynecology, Obstetrics, Pediatrics, Medical Jurisprudence, Dentistry, Veterinary Science, etc. By Robley Dunglison, M.D., L.L.D., Late Professor of Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College of Philadelphia. Twenty-third Edition, Thoroughly Revised, with the Pronunciation, Accentuation and Derivation of the Terms. By Thomas L. Stedman, A.M., M.D., Fellow of the New York Academy of Medicine. Cloth. Pp. 1212. Price, $8.00. Philadelphia and New York: Lea Brothers & Co. 1903.

For seventy years Dunglison's Dictionary, like Gray's Anatomy, has been a standard. It has held first place—and the only place for many years—as the medical dictionary of our country. Others have appeared and held high rank for awhile, and then have vanished. But Dunglison's still hung on and became an institution in medicine. And now we have the twenty-third edition "thoroughly revised," as the title-page says, which examination shows to be a fact. It is the old standby with all its old associations clinging to it, but nevertheless it is a thorough exemplar of twentieth century medicine. A critical examination for the discovery of the omission of recently created words has resulted in a failure to find the omission; the new words are there. Over 1,500 new definitions, according to the preface, have been introduced in this edition. A few of the old definitions have been rewritten in a more concise form, but most of the old ones have been left as they were originally. The illustrations are more of a feature than in previous editions. Many are in colors, and those illustrating the arteries (19) and the veins (10) are especially to be commended. Those of us who in our younger days dug out of "Dunglison" not a little of medical lore will welcome the old book made new again and will thank Stedman and Lea Brothers for making it possible still to refer with confidence and satisfaction to the friend of our youth.

PSYCHOTHERAPY in the Practice of Medicine and Surgery. By Sheldon Leavitt, M.D. Cloth. Pp. 247. Price, $2.00. Chicago: Gardner-Taylor Press. 1903.

The principles of psychic healing as laid down by Leavitt seem to be very near to the teaching of Mrs. Eddy, divested, however, of their pseudo-religious and other fraudulent accessories. He believes in subjective and objective minds; the former controlling the vital action being in itself controllable to some extent by the objective mind. In his treatise he says that "all disease has its origin in the mind, the subjective taking its cue from its environment" and that "the prevention of disease consists in keeping the subjective mind under the power of wholesome suggestion." "The cure of disease consists in the use of suggestion running counter to disease and the establishment of subconscious thoughts of health inculcated by unconscious volition." "All cures are essentially self cures." This is pretty near pure Eddyism. The author believes, nevertheless, in the use of drugs and thinks that they are practically only aids to suggestion. The book is a readable one, and has, it seems to us, some literary pretensions, but as a scientific work we would not give it a very high place.

HUNTINGTON'S ABDOMINAL ANATOMY. The Anatomy of the Human Peritoneum and Abdominal Cavity Considered from the Standpoint of Development and Comparative Anatomy. By George S. Huntington, M.D., Professor of Anatomy in the College of Physicians and Surgeons, Columbia University, New York City. Pp. 590, Including 300 Full-page Plates in Colors and Monochrome. De Luxe Edition. Price, $10.00 net. Philadelphia and New York: Lea Brothers & Co. 1903.

In this work the author says: "An attempt has been made to emphasize the value of embryology and comparative anatomy in elucidating the difficult and often complicated morphologic problems encountered in the study of human adult anatomy." The first chapter, or introduction, contains a concise statement of the main facts of vertebrate embryology in so far as they relate to the abdominal cavity and its contents. The work is then subdivided into four parts: "Anatomy of the Peritoneum and Abdominal Cavity, Comparative Anatomy of Foregut and Stomach"; "Anatomy of the Peritoneum in the Supracolic Compartment of the Abdomen"; "Large and Small Intestine, Ileocolic Junction and Cecum"; "Morphology of the Human Cecum and Vermiform Appendix." Of course, no attempt is made to cover the entire subject of comparative anatomy, but such examples are considered as may lead to a clearer and better understanding of the human adult form. The author shows not only a thorough knowledge of the entire subject from a scientific point of view, but has presented the matter in such an attractive and instructive form as to enable the surgeon and physician to make many deductions of the greatest practical value. It is seldom that one has the pleasure of reviewing a work which is so thoroughly scientific and so replete with the practical and important. It is an excellent work and can be heartily recommended.

VEASEY'S OPHTHALMOLOGY. A Manual of Diseases of the Eye. For Students and General Practitioners. By Clarence A. Veasey, A.M., M.D., Demonstrator of Ophthalmology in Jefferson Medical College, Philadelphia. 12mo. Pp. 410. With 194 Engravings and 10 Full-page Colored Plates. Cloth. Price, $2.00 net. Philadelphia and New York: Lea Brothers & Co. 1903.

Dr. Veasey has given us a most valuable text-book, which will be useful to both student and practitioner. Veasey has had a long experience as a teacher, and consequently is capable of producing, in a condensed form, an excellent volume on the subject of ophthalmology. The volume is made attractive as well as more valuable by the color plates and by the two hundred engravings which are well executed. The publishers have presented the book in an attractive form and free from typographic errors. The chapter on the affection of the ocular muscles is one of the best, clearest and most concise that has yet been written. The author has evidently made a careful study of sympathetic ophthalmitis, as he has under that head given a condensed but at the same time a careful and thorough description of this most interesting disease.

THE MEDICAL NEWS VISITING LIST FOR 1904. Weekly (Dated for 30 Patients); Monthly (Undated, for 120 Patients per Month); Perpetual (Undated, for 30 Patients Weekly per Year); 60-Patients (Undated, for 60 Patients Weekly per Year). The Weekly, Monthly and 30 Patient Perpetual Contain 32 Pages of Data and 160 Pages of Classified Blanks. The 60-Patient Perpetual Consists of 256 Pages of Blanks Alone. Bound in Flexible Leather, with Flap and Pocket, Pencil and Rubber, and Calendar for Two years. Price, $1.25. Thumb-letter Index, 25 cents Extra. Philadelphia and New York: Lea Brothers & Co. 1903.

This excellent pocket companion comes to us in practically the same form as in former years. The matter has been revised and brought thoroughly up to date. It is one of the most useful pocket visiting lists that is issued and contains important tables, poisons and antidotes, etc., in a compact form.

PHYSICIANS' POCKET ACCOUNT BOOK. By J. J. Taylor, M.D. Leather. Pp. 200. Price, $1.00. Philadelphia: Published by the Medical Council.

This is a neat, compact, easily kept account book that can be carried in the pocket without inconvenience and contains a large amount of information for the general practitioner. The form of keeping the accounts is in compliance with the legal requirements of practically all the states, making it especially valuable on this account.

SUCCESS IN DENTAL PRACTICE. A Few Suggestions Relative to the Most Approved Methods of Conducting a Practice. By C. N. Johnson, M.A., L.D.S., D.D.S., Professor of Operative Dentistry in the Chicago College of Dental Surgery. Cloth. Pp. 159. Price. $1.25. Philadelphia and London: J. B. Lippincott Co. 1903.

This little work is full of useful hints to the dental practitioner. Written by a man of years of ripe experience, it can not but be of great benefit to the dentist, especially to those about to begin practice. Every dental practitioner should have it conveniently at hand to peruse at his leisure moments.

ELECTRO-STATIC MODES OF APPLICATION, THERAPEUTICS AND THE USES OF THE RÖENTGEN RAY. By William Benham Snow, M.D., Professor of Electro-Therapeutics and Radiotherapy in the New York School of Physical Therapeutics. Second Edition. Revised and Enlarged. Contains More Than 100 Illustrations. Including Ten Full-page Half-tones, Showing the Various Methods of Posturing and Treating Conditions. Cloth. Pp. 302. Price, $3.00. New York: A. L. Chatterton & Co.

This work first appeared about two years ago, and has now been corrected and brought up to date.

Miscellany.

We need to educate the medical profession at large as well as the public on the extreme value of postmortem examinations. These examinations . . . would help us at every step of our work and do more to advance our profession than any other one thing.—*Journal of the Kansas Medical Society.*

The local medical society ought to know all about the doings of its local board of health, about its community water supply, the sewerage system, the sanitation of its school houses. It ought to lend its influence toward making clean, beautiful streets, regulating various nuisances, smoke, unnecessary noises, etc. The local society ought to have something actively to say and to do about the grossly immoral advertising and the nauseating patent medicine notices that appear in the local papers.—*Iowa Medical Journal.*

A Useful Discovery.—For 40 years physicists have been seeking some substance to serve as a screen, cutting off all the light and heat-giving rays of the spectrum, while allowing the invisible ultra-violet rays to pass. Finally, Prof. R. W. Wood of the Johns Hopkins University, has discovered the long-sought substance, which bears the name of nitrosodimethylanilin. When combined with cobalt glass, this substance furnishes a screen which allows only ultra-violet rays to pass through. The discovery is of importance for some difficult scientific investigations.—*Carolina Med. Jour.*

Opium in Infantile Diarrhea.—Kerr, in the *Brooklyn Medical Journal*, gives these rules: Use opium "always alone, never in combination." The indications for its use are: "1. When the evacuations are large and watery. 2. When they are small and nagging. 3. When, late in the disorder, the taking of food causes an almost immediate evacuation. Its use is contraindicated in the stage of active diarrhea before the bowel has been cleared out, or where the passages are foul smelling. It should never be used in the presence of high temperature and cerebral symptoms."

Physiologic Importance of Abundant Light.—The habit of keeping the window-shades down, which is so common a practice even when there is no direct sun-glare on the window, is a direct setting at naught of physiologic principles, which teach the importance to health of both body and mind of an abundance of light. Sir James Crichton-Browne, in an address on "Light and Sanitation" delivered at the jubilee conference of the Manchester and Salford Sanitary Association, said: "I have spoken of light as purifying our atmospheric environment and as freeing us from certain superficial parasitic distempers, and I wish now to remind you that it has still more deep and intimate human relations of a sanitary nature; for light is a necessary condition of mental and bodily well-being. Its tonic psychical effects are everywhere recognized. All properly organized men and women love the light, and it is not merely to children that darkness brings with it a sense of powerlessness, danger, and alarm. Essential for all the purposes of life, for the supply of oxygen on which existence depends, light is a universal stimulus."—*N. Y. Medical Journal.*

An Aseptic Newspaper.—The Huron (S. D.) *Journal-World* and its managing editor, Mr. W. E. Holbein, deserve great credit for a clean sheet, and a refreshing freedom from offensive advertising. This paper does not carry in its columns the advertisement of a patent medicine or a medical faker. A country newspaper that has the courage to exclude such matter and the moral strength to decline a source of revenue from such advertising should receive applause, commendation and support from every right-minded physician. The people of Huron are to be congratulated on the presence of such a man as Mr. Holbein, and Mr. Holbein is to be congratulated for living in a community that will support a clean and reputable paper. The *Lancet* extends its compliments, and expresses the hope that more country papers will follow this good example. It is vain to expect that the city dailies will follow this twentieth century leader—the revenue is too great from photographically illustrated testimonials, fakers of nauseating fame, and luring advice for criminal acts. Let us look forward to the time when the people shall be educated to read the news and not to waste their gray matter on useless, nasty and body-destroying advertisements.—*Northwestern Lancet.*

No Contract Practice.—The following resolutions were adopted by the Hillsborough (Fla.) County Medical Society, at its November meeting:

WHEREAS, Some of the principal objects of our organization are to enable its members to receive just and full compensation for their services, and to maintain fair and equal ethical relations among its members, and to maintain dignified professional relations toward each other, and to promote the practice of more scientific medicine, and to protect its members from unjust discriminations in acquiring practice;

WHEREAS, There are present among us certain companies or societies conducted on the mutual benefit plan, which make and offer to make exclusive contracts with physicians and surgeons wherein the compensation for their services is less than the conventional fees for such services, and

WHEREAS, These societies have come to be recognized the world over as being demoralizing and baneful to the interests of the profession of medicine; therefore, be it

Resolved, That it is the sense of this society that entering into contracts to do medical and surgical service with any society, company, corporation or association, to the exclusion of any other physician or physicians or for compensation less than the conventional fees for such services, is undignified and unprofessional conduct and is injurious to the profession, and that the members of this society shall not enter into such contracts, *Provided*, That this resolution does not apply to United States Army surgeons, United States Marine-Hospital surgeons, United States Navy surgeons, nor to any city, county, state or national health officer nor to railroad surgeons.

Resolved, That we send a copy of these resolutions to each physician in Hillsborough County, requesting his co-operation in carrying out the same. Be it further

Resolved, That this resolution shall be and is by its adoption a part of the constitution and by-laws of this society, the same to be known as Amendment 1 of the by-laws.

Mrs. Eddy As She Really Is.

CLARENCE L. WHEATON, M.D.
DENVER.

A well-known lay journal* recently published an article under the above caption, referring to incidents in Mrs. Eddy's home life, in which appears the following:

Promptly at 2 o'clock the carriage appears every day, a handsome turnout; but unless it be for the heavy silver mountings of the harness with the small ornamental letter E here and there, there is nothing whatever about to attract special attention. It is a closed carriage and the driver himself wears no livery other than the silk hat and black coat. Her secretary always sits on the seat by the driver.

This brief description of Mrs. Eddy's livery is preceded by an account of her palatial home. Mrs. Eddy has indeed sown well the seed that could bring forth this luxurious harvest. I was not blinded, however, by the glare and glitter of it all; I thought of other things. I thought of the ignorant multitude who daily worship at the shrine of this self-appointed goddess of a new faith. I thought of the millions of homes on which the shadows nightly fall and the thousands of weeping mothers with broken hearts whose loved ones have journeyed thither "across the black interminable ocean, unfluctuating and voiceless, which perchance stretches between these earthly coasts and those invisible shores," a sacrifice on the altar of the new faith.

I could see the empty trundle-bed, which so often lulled to sweet dreams the little boy blue of that home, and I thought of the countless thousands of innocents sacrificed to this delusion of the Twentieth Century, that stalks about in the garb of a "Christian" science. I thought of the millions and millions of followers of a faith that belongs to a voiceless age; to an age of darkness, ignorance and superstition; to an age in which there shines no star, where laws were neglected, an age of injustice and agony. I thought of this faith that offers a hope to the weary invalid, a hope that must fade away as the dew on the sun-kissed petals of the meadow flower, a hope that must vanish like the Magic Lake in mirage, above the silent and lonely sand-shrouded desert.

The Hygienic Laboratory of the U. S. Public Health and Marine-Hospital Service.

In August, 1887, the Hygienic Laboratory of this service was established in New York at the Marine Hospital, Staten

* The Ladies' Home Journal, November. The standing of this magazine would lead one to expect better things of it than endorsing this idiotic travesty on religion and lending its columns to help on such money-making schemes. The article should have appeared in the advertising pages: it was accompanied by an editorial note stating that it was approved for publication by the "profitess."—Ed.

Island. It was transferred to Washington, with headquarters on the upper floor of the Butler Building, on June 11, 1891. Five acres of the reservation of the Naval Museum of Hygiene were set aside for a site, and an appropriation of $35,000 was made by Congress, March 3, 1901, for a new building. This building is now completed and is being equipped. It will be occupied about Jan. 1, 1904.

The building is constructed of dark, hard-burned brick, with a basement, two stories and an attic. On the first floor are located the general office, the private offices of the director and assistant director, the zoologic laboratory, and the private office of the chief of that division. At the western end of this floor is the room devoted to photography. In this room will be placed the microphotographic apparatus, cases for the preservation of negatives and for the storage of special apparatus. This room is provided with a roll curtain, for lantern exhibitions to be given in connection with the instruction of student-officers. South of the main entrance, on this floor, is the library, which will contain shelf room for about 10,000 volumes. This room is provided with a long table in order that it may be used for board meetings.

The second floor has in the center, facing north, three rooms devoted to the private offices of the chiefs of the divisions of chemistry, pharmacology, and pathology and bacteriology, respectively. The west room is for the division of pathology and bacteriology. This room has benches so arranged that nine officers may be accommodated, each with an entire window for his own use. The small sterilizers, postmortem table, tables for the microtomes and the paraffin bath are placed in this room. By an ingenious arrangement, at each desk there is delivered a solution of trikresol, distilled water, tap water, and gas for a Bunsen burner. The east room on this floor is for the use of the divisions of chemistry and pharmacology. Benches, with necessary lockers, drawers, hoods and sinks are provided. This floor also contains the incubator and cold rooms. The incubator is maintained at a uniform temperature by means of an electric heater. The cold room is cooled by means of a special system of cold-air pipes.

In the basement are located the heating plant, necessary storage for coal and the large sterilizers. The building is provided with two elevators running from the basement to the attic.

An Act of Congress, approved July 1, 1902, provided that there should be an advisory board for the Hygienic Laboratory; this board to consist of three competent experts detailed from the Army, the Navy and the Bureau of Animal Industry, respectively, together with the director of the laboratory and five additional members on said board, to be appointed by the surgeon-general of the Public Health and Marine-Hospital Service, with the approval of the Secretary of the Treasury, who shall be skilled in laboratory work in its relation to public health. This act also provided that there shall be appointed, whenever in the opinion of the surgeon-general commissioned medical officers are not available for duty on this detail, competent persons to take charge of the divisions of chemistry, zoology and pharmacology. These chiefs of divisions shall be men skilled in their respective lines of scientific research work, especially in relation to the public health.

The results of the researches in the laboratory are published in laboratory bulletins. During the past year nine bulletins have been issued from the laboratory. Some of them, on account of their great importance from a public health standpoint, have attracted wide attention.

Plans are now under way for the production in the laboratory of a standard diphtheritic antitoxin for distribution to manufacturers, those engaged in research work, and others.

Officers of the service are detailed to the laboratory from time to time for special instruction in bacteriology and pathology. The course given is very complete, extending over a period of about twelve months. When these officers have completed the course they are competent to do independent research work.

The Act of Congress, approved July 1, 1902, entitled "An act to regulate the sale of viruses, serums, toxins, and analogous products in the District of Columbia, to regulate interstate traffic in said articles, and for other purposes," and regulations approved in accordance with said act, placed the supervision of plants manufacturing these products under the Public Health and Marine-Hospital Service. The laboratory examination of these products is conducted in the Hygienic Laboratory.

State Boards of Registration.

COMING EXAMINATIONS.

State Board of Examiners of Alabama, Montgomery, Dec. 1 to 10. Chairman, W. H. Sanders, M.D., Montgomery.

New Mexico Board of Health, Santa Fe, Dec. 7. Secretary, Dr. D. B. Black, Las Vegas.

Examining Board of Medical Society of Delaware, Dover, Dec. 8. Secretary, Dr. P. W. Tomlinson, Wilmington.

Board of the Homeopathic Medical Society of Delaware State and Peninsula, Wilmington, Dec. 8.

Ohio State Board of Medical Registration and Examination, Columbus, Dec. 8-10. Secretary, Dr. Frank Winders, Columbus.

Missouri State Board of Health, Southern Hotel, St. Louis, Dec. 14, 15 and 16. Secretary, Dr. W. F. Morrow, Kansas City.

Medical Council, Philadelphia, Dec. 15. Secretary, Dr. Isaac B. Brown, Harrisburg.

Medical Examining Board of Virginia, Lynchburg, Dec. 15-18. Secretary, Dr. R. S. Martin, Stuart.

Colorado State Board of Medical Examiners, 1723 Tremont St., Denver, Dec. 22-24. Secretary, Dr. S. D. Van Meter, Denver.

Louisiana Report.—Dr. Felix A. Larue, secretary and treasurer of the Louisiana State Board of Medical Examiners, reports the written examination held at New Orleans, Oct. 26 and 27, 1903, as follows: Number of subjects, 10; questions, 50; percentage, 75; candidates, 30; passed, 22; failed, 8. Following are the colleges of the candidates, the years of graduation and the grades attained:

PASSED.

Tulane University, (1901) 82.6,* 88.4; (1903) 84.4, 75.2, 80.8, 78.2, 79.6.		
Memphis Hospital Med. Coll., (1903) 75.8, 77.2, 75.6, 75.		
Univ. of the South, Sewanee, Tenn., (1903) 75.6;* (1899) 77.		
Baltimore Medical College	(1903)	84.2
Jefferson Medical College	(1902)	92.8
University of Tennessee	(1903)	81.2
University Medical College, Kansas City	(1903)	78.0
Louisville Medical College	(1886)	76.6*
Fort Worth University	(1903)	86.6
New Orleans University	(1903)	77.2*
Walden University	(1903)	79.6*
Illinois Medical College, Chicago	(1903)	75.2

FAILED.

Memphis Hospital Medical College, (1903) 67.4; (1896) 66.0.*		
University of Brussels (Belgium)	(1872)	58.2
University of the South (Sewanee)	(1903)	69.0
Kentucky School of Medicine	(1898)	64.2*
Vanderbilt University	(1894)	71.0
Walden University	(1903)	71.8
New Orleans University	(1902)	69.0†

* Second trial. † Third trial.

District of Columbia Report.—Dr. William C. Woodward, secretary of the Board of Medical Supervisors of the District of Columbia, reports the oral and written examination held at Washington, D. C., Oct. 9 to 14, 1903, as follows: Number of subjects, 17; questions, 80 written; percentage, 75; candidates, 28; passed, 23; failed, 5. Following are the colleges of the candidates, the years of graduation and the grades attained.

PASSED.

Bellevue Hospital Medical College	(1897)	82.62.
Chicago Homeopathic College	(1888)	75.03.
Columbian University	(1901)	86.84; (1902) 90.37, 88.93; (1903) 86.09, 86.31, 89.21, 86.18
Georgetown University	(1901)	92.00, 82.34, 82.68, 85.62, 88.81.
Howard University	(1902)	81.62; (1903) 79.21, 78.09.
Johns Hopkins Medical School	(1901)	86.62; (1902) 91.09, 84.25.
Tufts Coll. Med. School, Boston	(1897)	85.12.
University of Maryland	(1899)	88.03.
University of Pennsylvania	(1902)	77.15.

FAILED.

Cleveland Medical College	(1893)	56.50.
Coll. of Phys. and Surgs., Baltimore	(1893)	71.90.
Columbian University	(1903)	71.34.
Howard University	(1903)	72.12; (1902) 69.71.

The secretary does not send the questions asked at the examination because "the board," he says, "does not consider the publication of such questions compatible with the best interests of medical examining and licensing boards."

Illinois October Report.—Dr. James A. Egan, secretary of the Illinois State Board of Health, reports the written examination held at Chicago, October 21 to 23, 1903, as follows: Number of subjects examined in, 11; total questions, 110; percentage required to pass, 75; candidates examined, 49; passed, 43; failed, 6. The following were the colleges represented, with year of graduation and the grade attained:

PASSED.

Northwestern Univ., Chicago.....(1903) 86, 88, 84, 86, 86.
Rush Medical College, Chicago.....(1902) 85; (1903) 83, 85, 86, 90, 85, 84, 78, 86, 88, 86.
University of Michigan.....(1888) 75; (1898) 88.
Johns Hopkins Univ., Baltimore.....(1899) 85; (1903) 87.
Illinois Medical College, Chicago.....(1903) 86, 85, 83, 83, 82, 85.
Baltimore Medical College.....(1903) 85.

In addition to the above, one candidate withdrew on account of sickness and another was suspended for dishonesty in the examination.

Washington Report.—Dr. P. B. Swearingen, Tacoma, secretary, Washington State Board of Medical Examiners, reports a written examination at Spokane, July 6-7, 1903, as follows: Subjects covered, 16; questions, 139; candidates, 85; passed, 76; failed, 9. The percentage required of recent graduates was 75, of old practitioners, 70. The following is a summary by colleges:

PASSED.

Northwestern Univ., Chicago, (1893) 92 3/7; (1898) 90 3/7; (1902) 85 2/7.
Keokuk Medical College, (1901) 70 4/7.
Kansas City Medical College, (1903) 82½; (1899) 83; (1903) 77 1/21; (1900) 77.
Louisville Medical College, (1901) 78 9/14; (1890) 70 9/14.
Harvard Medical College, (1903) 81 6/7.
Boston University, (1903) 83 5/14.
Detroit Medical College, (1902) 86 13/14; (1902) 77 13/14; (1902) 83½; (1895) 78 3/14.
Ann Arbor Medical College, (1868) 73 3/7.
University of Michigan, (1886) 73 11/14.
University of Minnesota, (1892) 83½; (1903) 84 2/7; (1902) 90¼; (1902) 91 3/7; (1901) 77; (1894) 76 3/14.
University of Maryland, (1893) 85 2/7.
Medical School of Maine, (1879) 73 2/7.
Barnes Med. Coll., (1903) 81 1/84; (1897) 79 2/7.
Marion Sims Medical College, (1892) 74½.
Homeopathic Medical College, St. Louis, (1898) 78 5/14.
Missouri Medical College, (1899) 77 11/14.
St. Louis Medical College, (1873) 70 5/7.
Washington University, St. Louis, (1901) 83¼.
Bellevue Medical College, (1897) 84 1/7.
Ohio Medical College, (1901) 74 15/28.
Cleveland Medical College, (1883) 72 3/14.
Cincinnati Medical College, (1902) 75.
Eclectic Medical College, Mancelona, Mich., (?) (1879) 70 1/7.
Eclectic Medical College, Pennsylvania, (1868) 82.
University of Pennsylvania, (1895) 80 1/18; (1868) 72 1/14.
Hahnemann Medical College, Philadelphia, (1899) 93 3/14.
Cooper Medical College, (1903) 81 13/14; (1903) 87¾.
University of California, 85 3/7.
College of Physicians and Surgeons, Chicago, (1901) 85 5/7; (1903) 78 4/7; (1901) 79 1/14; (1903) 75 2/7; (1903) 91 3/14; (1896) 83 9/14; (1902) 83½.
College of Physicians and Surgeons, San Francisco, (1902) 84 3/7.
College of Physicians and Surgeons, St. Louis, (1903) 83 5/7.
Illinois Medical College, (1902) 79 5/7.
Rush Medical College, (1881) 69 9/14; (1888) 72½; (1903) 77 9/14; (1902) 85 5/7; (1901) 82 3/14.
Chicago Homeopathic Medical College, (1896) 82 4/7.
Hahnemann Medical College, Chicago, (1903) 78 6/7.
Woman's Medical College (place not given), (1903) 76 6/7.
Tennessee Medical College, (1895) 75 3/14; (1901) 75 2/7.
Washington, D. C., College (?), (1902) 81 5/7.
National University, Washington, D. C., (1901) 81 3/7.
McGill University, (1874) 82½, 85; (1902) 85 6/7; (1901) 84.
Central Medical College, St. Joseph, Mo., (1900) 89 5/7.
Trinity Medical College, (1892) 70 5/7; (1894) 82¼.
Manitoba Medical College, (1899) 96.

FAILED.

Louisville Medical College, (1898) 60 13/14; (1900) 50 1/7.
Kentucky School of Medicine, (1897) 73 1/7.
St. Joseph's Medical College, (1887) 56 6/7.
New Hampshire Medical College, (1875) 63 1/28.
Eclectic Medical Institute, Cincinnati, (1900) 65 4/7.
California Medical College, (1902) 58 4/7.
Cooper Medical College, (1897) 71 4/7.
Rush Medical College, (1896) 62 5/21.

The Public Service.

Army Changes.

Memorandum of changes of stations and duties of medical officers of the U. S. Army for the week ending Nov. 28, 1903.

Torney, G. H., deputy surgeon-general, appointed a member of examining board at San Francisco for promotion of medical officers.

Kilbourne, H. S., deputy surgeon-general, relieved as member of examining board at San Francisco for promotion of officers of the medical department.

Grubbs, R. B., asst.-surgeon, relieved from duty at General Hospital, Presidio of San Francisco, and ordered to Fort Wright, Wash.

Rand, I. W., asst.-surgeon, relieved from duty at Fort Wright, Wash., and ordered to Ord Barracks, California.

Adair, Geo. W., deputy surgeon general, having reported his arrival at San Francisco, Cal., is ordered to St. Paul, Minn., for duty as chief surgeon, Department of Dakota.

Byrne, Charles B., asst.-surgeon-general, relieved from duty as chief surgeon, Department of Dakota, and ordered to proceed to Omaha, Neb., for duty as chief surgeon, Department of Missouri.

Girard, J. B., asst.-surgeon-general, relieved from duty as chief surgeon, Department of Missouri, and ordered to San Antonio, Texas, for duty as chief surgeon, Department of Texas.

Kilbourne, H. S., deputy surgeon-general, relieved as chief surgeon, Department of California, and ordered to proceed to Manila, about Dec. 1, 1903.

Girard, A. C., asst.-surgeon-general, relieved from duty in the Division of the Philippines on the arrival of Colonel Kilbourne, and ordered to San Francisco, Cal., and on arrival to report by telegram to the Adjutant General of the Army.

Brechemin, Louis, surgeon, relieved from duty at Ord Barracks, Monterey, Cal., and ordered to San Francisco, Cal., to assume charge of the medical supply depot in that city.

Torney, G. H., deputy surgeon-general, relieved from duty at medical supply depot and to report to the commanding general, Department of California, for temporary duty as chief surgeon of that department.

Hoff, Jno. Van R., deputy surgeon-general, granted thirty days' leave, to take effect in December, 1903.

Webber, H. A., asst.-surgeon, relieved from duty in Division of the Philippines, now at San Francisco, Cal., will proceed to Fort Walla Walla, Wash., for duty.

Morse, Arthur W., asst.-surgeon, relieved from duty at Fort Walla Walla, Wash., and ordered to Vancouver Barracks, Wash.

Brooks, William H., asst.-surgeon, relieved from duty at Vancouver Barracks, Washington, and ordered to U. S. General Hospital, Washington Barracks, D. C., for duty.

Jean, Geo. W., asst.-surgeon, relieved from duty in Division of the Philippines and ordered to Fort Adams for duty.

Bushnell, Geo. E., surgeon, granted seven days' leave, with permission to apply for twenty-three days' extension.

Richards, Alfred, contract surgeon, granted one month's leave of absence and relieved from duty at Fort Hunt, Virginia.

Bailey, Edward, contract surgeon, relieved from duty at Fort Columbia, Washington, and ordered to San Francisco, Cal., to sail January 1 for Philippine service.

Turner, Samuel S., contract surgeon, ordered from Chicago, Ill., to Fort Columbia, Washington, for duty.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending Nov. 28, 1903:

Huntington, E. O., surgeon, sick leave extended for three months.

Fauntleroy, A. M., asst.-surgeon, when discharged for treatment, ordered to the *Scorpion*.

DuBose, W. R., medical inspector, ordered to duty as assistant to the Bureau of Medicine and Surgery, Navy Department.

Urie, J. F., surgeon, detached from assistant chief Bureau of Medicine and Surgery and ordered to the *Missouri*.

Grayson, C. T., A. A. surgeon, detached from the Naval Proving Ground, Indian Head, Md., and ordered to the Naval Hospital, Washington, D. C.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Nov. 26, 1903:

Sawtelle, H. W., surgeon, granted leave of absence for two days from November 27.

Gassaway, J. M., surgeon, department letter granting him leave of absence for one month, amended so that said leave shall be for twenty-five days from October 12.

Stoner, G. W., surgeon, leave of absence for five days from Nov. 24, 1903, under paragraph 189 of the Regulations.

Wickes, H. W., P. A. surgeon, granted leave of absence for five days from November 28.

Clark, T., P. A. surgeon, to proceed to St. Johns, N. B., and assume temporary charge of service during absence of A. A. Surgeon W. C. Billings.

Lumsden, L. L., P. A. surgeon, on expiration of leave of absence to remain at New Orleans and await assignment.

Billings, W. C., Corput, G. M., and Kerr, J. W., asst.-surgeons, to proceed to Washington, D. C., and report to chairman of examining board to determine their fitness for promotion to the grade of passed assistant surgeon.

Robinson, D. G., asst.-surgeon, to report to chairman of examining board, Port Townsend, Wash., to determine his fitness for promotion to the grade of passed assistant surgeon.

Currie, D. H., asst.-surgeon, to proceed to San Francisco Quarantine, and assume temporary charge of service during absence of P. A. Surgeon H. S. Cumming.

Manning, H. M., asst.-surgeon, relieved from duty at Stapleton, N. Y., and directed to proceed to Honolulu, T. H., and report to chief quarantine officer for duty.

Maguire, E. S., pharmacist, department letter granting leave of absence for thirty days from Dec. 5, 1903, amended so that said leave shall be from December 1.

BOARDS CONVENED.

Board to meet at Washington, D. C., Dec. 7, 1903, for examination of Asst.-Surgeons W. C. Billings, J. W. Kerr and G. M. Corput, to determine their fitness for promotion to the grade of passed assistant surgeon. Detail for the board: Asst.-Surgeon-General L. L. Williams, chairman; Asst.-Surgeon-General W. J. Pettus; Asst.-Surgeon-General G. T. Vaughan, recorder.

Board to meet at Port Townsend, Wash., Dec. 14, 1903, for examination of Asst.-Surgeon D. E. Robinson, to determine his fitness for promotion to the grade of passed assistant surgeon. Detail for the board: P. A. Surgeon J. H. Oakley, chairman; P. A. Surgeon H. S. Cumming; P. A. Surgeon M. H. Foster, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Nov. 27, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, Nov. 8-21, 21 cases.
Colorado: Denver, Oct. 18-31, 10 cases.
Illinois: Belleville, Nov. 8-21, 11 cases.
Louisiana: New Orleans, Nov. 15-21, 1 case.
Massachusetts: Lawrence, Nov. 15-21, 1 case.
Michigan: Detroit, Nov. 15-21, 4 cases.
New Hampshire: Manchester, Nov. 15-21, 3 cases.
New Jersey: Camden, Nov. 15-21, 4 cases, 2 deaths.
New York: New York, Nov. 15-21, 4 cases.
Ohio: Nov. 15-21, Cleveland, 1 case; Youngstown, 11 cases.
Pennsylvania: Erie, Nov. 8-21, 3 cases; Nov. 15-21, Altoona, 1 case; Carbondale, 2 cases; Johnstown, 3 cases; Philadelphia, 68 cases, 7 deaths; Pittsburg, 32 cases, 6 deaths.
Tennessee: Memphis, Nov. 15-21, 3 cases.
Utah: Salt Lake City, Nov. 8-14, 3 cases.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Nov. 1-7, 9 cases.
Brazil: Rio de Janeiro, Oct. 19-25, 40 cases, 34 deaths.
Canada: Manitoba, Winnipeg, Nov. 8-14, 1 case.
Colombia: Barranquilla, Nov. 2-18, 1 death.
Ecuador: Guayaquil, Oct. 18-31, 2 deaths.
France: Paris, Nov. 1-7, 3 cases.
Great Britain: Glasgow, Nov. 7-13, 7 cases, 1 death; Manchester, Oct. 25-Nov. 7, 7 cases; Newcastle-on-Tyne, Nov. 1-7, 6 cases.
Java: Batavia, Oct. 11-17, 21 cases, 6 deaths.
Mexico: City of Mexico, Oct. 8-15, 1 case.
Netherlands, Amsterdam, Nov. 8-14, 3 cases.
Russia: Odessa, Oct. 19-25, 5 cases, 1 death; St. Petersburg, Oct. 25-Nov. 7, 126 cases, 2 deaths; Warsaw, Oct. 18-24, 2 deaths.
Spain: Barcelona, Oct. 25-Nov. 7, 2 deaths.
Turkey: Smyrna, Oct. 19-Nov. 1, 68 deaths.

SMALLPOX—INSULAR.

Philippine Islands: Cebu, Sept. 1-30, 5 cases, 1 death; Manila, Sept. 27-Oct. 10, 1 case.

YELLOW FEVER—UNITED STATES.

Texas: Cannel, Nov. 19-23, 4 cases; Laredo, Nov. 20-23, 68 cases, 5 deaths; Minera, Nov. 14-23, 6 cases; San Antonio, Nov. 15-23, 7 cases, 2 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Oct. 19-25, 1 case.
Mexico: Ciudad Victoria, Oct. 25-Nov. 7, 14 cases, 8 deaths; Coatzacoalcos, Nov. 1-7, 2 cases, 2 imported; Oct. 25-Nov. 7, Linares, 86 cases, 17 deaths; Merida, 4 cases, 2 deaths; Tampico, 3 cases; Tehuantepec, 2 deaths; Vera Cruz, Nov. 7-14, 17 cases, 5 deaths.

CHOLERA—INSULAR.

Philippine Islands: Sept. 27-Oct. 10, Manila, 90 cases, 84 deaths; Provinces, 952 cases, 750 deaths.

CHOLERA—FOREIGN.

China: Shanghai, Oct. 3-10, 7 deaths.
Japan: Magasaki, Oct. 20-26, 49 cases, 27 deaths; Yokohama, Oct. 4-10, 1 case, 1 death.
Straits Settlements: Singapore, Sept. 1-30, 9 deaths; Singapore, Sept. 27-Oct. 3, 1 case, 1 death.
Turkey: Syria, Alexandretta, Oct. 18-24, 2 cases, 1 death.

PLAGUE—INSULAR.

Philippine Islands: Cebu, Sept. 1-30, 11 cases, 8 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Oct. 19-25, 54 cases, 20 deaths.
China: Newchwang, Sept. 26-Oct. 3, 144 cases, 142 deaths.
India: Bombay, Oct. 20-27, 64 deaths; Calcutta, Oct. 18-24, 13 deaths.
Japan: Yokohama, May 10-Oct. 17, 29 cases, 23 deaths.

Medical Organization.

California.

MERCED COUNTY MEDICAL SOCIETY.—The physicians of the county met at Merced, November 12, and organized a society on the standard plan with the following officers: Dr. Edward S. O'Brien, president; Dr. Hiram N. Rucker, vice-president; Dr. Walter E. Lilley, secretary; Dr. Herbert De Loss, treasurer, and Drs. A. M. Smith and William A. Whitlock, censors, all of Merced. Dr. Philip M. Jones, San Francisco, trustee of the state society, was present and aided in the work of organization.

Louisiana.

ST. MARY PARISH MEDICAL SOCIETY.—Dr. William M. Perkins, New Orleans, secretary of the Louisiana State Medical Society, and Dr. G. L. Williams, Oak Ridge, councilor for the Fifth District, met with the physicians of the parish, October 24, and organized a county society on the standard plan with the following officers: President, Dr. Sterling J. Gates, Franklin; vice-president, Dr. William J. McLennan, Morgan City, and secretary-treasurer, Dr. Gustave A. Sigur, Glencoe.

BI-PARISH MEDICAL SOCIETY OF ST. JOHN THE BAPTIST AND ST. CHARLES PARISHES.—The physicians of these two parishes met at Edgard, November 2, and organized a bi-parish society with the aid of Dr. Andrew G. Friedericks, councilor for the Second District, and Dr. Louis G. Le Beuf of New Orleans. The following officers were elected: President, Dr. Louis T. Donaldson, Reserve; vice-president, Dr. Newton C. Stevens, Ama, and Dr. Norbert J. Simon, Wallace, secretary and treasurer. The society includes in its membership all the physicians in these two parishes.

North Carolina.

WAKE COUNTY MEDICAL SOCIETY.—In accordance with the standard plan suggested by the American Medical Association, the physicians of Wake County met with Dr. Hubert A. Royster, councilor for the Sixth District, and organized a county society. Dr. Albert Anderson, Wilson, councilor for the Fourth District, was present, and addressed the assembly on the subject of organization. The initial membership was 24. The following officers were elected: Dr. J. J. L. McCullers, McCullers, president; Dr. Lawrence B. Young, Rolesville, vice-president; Dr. Harry G. Utley, Apex, secretary; Dr. Kemp B. Battle, Raleigh, treasurer, and Drs. James M. Templeton, Carey; Robert S. McGeachy, Raleigh, and Benjamin S. Utley, Holly Springs, censors.

Oregon.

LANE COUNTY MEDICAL SOCIETY.—At the annual meeting held in Eugene, November 14, the society decided to reorganize on the standard plan.

Washington.

PACIFIC COUNTY MEDICAL SOCIETY.—This society, of which Dr. George W. Overmeyer, South Bend, is president; Dr. Wilson Grewell, South Bend, secretary; Dr. William Klamke, Ilwaco, vice-president, and Dr. Kennedy, South Bend, treasurer, has received its charter from the State Society.

Wisconsin.

WESTERN WISCONSIN DISTRICT MEDICAL SOCIETY.—This society, which includes the physicians of Eau Claire, St. Croix, Chippewa, Pierce, Dunn and Pepin counties, was organized at Eau Claire, November 17, with Dr. Eugene L. Boothby, Hammond, as president.

Texas.

FAYETTE COUNTY MEDICAL ASSOCIATION.—On November 11 the physicians of Fayette County met at La Grange and, after Dr. Walter Shropshire, Yoakum, councilor for the Eighth (DeWitt) District, had explained the standard plan of organization, perfected the organization of a county society with the following officers: President, Dr. Henry A. Tutwiler, Flatonia; vice-president, Dr. Otto Ehlinger, La Grange; secretary, Dr. P. Chapman, Winchester, and censors, Drs. W. Allen, Flatonia; A. Posch, Round Top, and John S. Zvesper, Ammannsville.

Society Proceedings.

COMING MEETINGS.

Southern Surgical and Gynecological Association, Atlanta, Ga., Dec. 15-17.
Western Surgical and Gynecological Association, Denver, Dec. 28-29.

ACADEMY OF MEDICINE OF CLEVELAND.

Twelfth Regular Meeting, held Oct. 16, 1903.

The President, Dr. Harris G. Sherman, in the Chair.

Importance of the Etiologic Factor in the Treatment of Cystitis.

DR. WILLIAM E. LOWER, the author of this paper, deplored the fact that so many cases of cystitis were treated symp-

tomatically for long periods without having recourse to a cystoscopic examination which would often clear up the exact cause and lead to appropriate treatment and a speedy cure. Many physicians did not realize the ease and safety of this procedure in the hands of a specialist. In an extended series of cases he had failed to see any bad results from such an examination, one of the requirements, however, being an accurate knowledge of the appearance of the normal bladder. In nearly all instances bacteria are causative agents, the principal offenders being the colon bacillus, the staphylococcus, either the albus, aureus or citreus, the streptococcus, the tubercle bacillus and the gonococcus, the last two being rarely found alone. He insisted on the importance of treating urethral strictures, which often caused diverticula in the thickened bladder wall forming pockets of pus which often defied evacuation by simple vesical irrigation. When an insuperable obstacle to free drainage from below exists he advises suprapubic drainage. The value of cystoscopy in case of calculi or foreign bodies in the bladder was instanced by cases in which repeated sounding had failed to locate a stone which was at once revealed by cystoscopic examination.

Fourth of July Wounds.

DRS. DUDLEY P. ALLEN and A. I. LUDLOW presented a paper entitled "Wounds from Blank Cartridges, Observations on Sixteen Cases Cared for at Lakeside Hospital about July 4, 1903." The injuries were located in the abdominal wall once, in the scrotum once, and in the hand fourteen times; in the abdominal case the external wound was very small, but increased in size deeper down, the whole thickness of the wall was penetrated and the wad was found imbedded in the intestinal wall; on admission to the hospital several days after the accident the patient was suffering from septic peritonitis, to which he speedily succumbed. Of the remaining 15 cases, 10 were treated as soon as admitted by free opening of the wound under anesthesia, excision of the badly torn fragments of tissue, removal of the particles of wad, irrigation and packing with iodoform gauze. All of these recovered. Three had been admitted within 12 hours of the injury, 6 within 2 days, and 1 within 9 days. The remaining 5 cases, 4 of which were wounded on the hand and 1 in the scrotum, were suffering from tetanus on admission, the symptoms having appeared in 1 case within 6 days of the injury, in 2 cases within 7 days, and in 2 cases within 8 days. All had been incised and cleansed before coming to the hospital, but in no instance had this been thorough, portions of the wad being found in all of them on further exploration and cleansing. Antitetanic serum was given to all, in one case by injection into the lateral ventricles; antispasmodics and anodynes and even chloroform inhalations were also administered, but all died.

Dr. Allen was prompted to read this paper both on account of the professional interest of the subject and also by a sense of its public importance. The toy pistol of to-day is a much more dangerous weapon than that of a few years ago, which used paper caps. The injuries caused by these blank cartridges are even worse than those caused by bullets. He felt that the increasing mortality demands prohibition of the toy pistol. Dr. Ludlow presented the results of cultural and animal experiments from this series of cases. In 5 of the 10 cases of wounds of the hand primarily treated at the hospital cultures in 3 were sterile, in 2 streptococcus and staphylococcus albus were found. In the 5 cases with tetanus one proved sterile, possibly from the free use of bichlorid in the wound; 2 showed the *Bacillus aerogenes capsulatus* and the *Bacillus mucosa capsulatus;* the two just mentioned occurred with the streptococcus and a pseudotetanus bacillus in one case and in another with the tetanus bacillus. In the animal inoculations from the case showing tetanus one guinea-pig died with tetanic symptoms, but only the *Bacillus aerogenes capsulatus* was recovered from the site of inoculation. A number of dogs and guinea-pigs were experimentally shot with blank cartridges, and in others subcutaneous implantations of the contents of cartridges were made, but so far none had developed tetanus. The time elapsed has not yet been sufficient to bar the possibility of its development in some of these. Dr. Ludlow thinks the occurrence of the *Bacillus aerogenes capsulatus* in all these fatal cases may be of value in suggesting further research along this line.

The paper was discussed by Drs. Briggs, Ladd, Hansom, Lincoln, Bunts, Friedrich, Rossenwasser, Wirt, Baker, Searl, Ballard and Moorehouse, some of whom quoted from the extensive article on this subject in THE JOURNAL, Aug. 29, 1903, entitled "The Fourth of July, 1903, Casualty List."

A resolution calling on the city council to prohibit the sale of toy pistols was then discussed and passed unanimously.

NORTH BRANCH PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Oct. 8, 1903.

Dr. H. Brooker Mills in the Chair.

SYMPOSIUM ON SYPHILIS.

Recognition and Treatment of Acquired Syphilis.

DR. S. LEON GANS read a paper in which he called attention to the importance of always bearing in mind the essential pathologic lesion—the round-cell infiltration. The chancre, he stated, was rather a building-up than a breaking-down process, and pus is not always present. They usually appear only singly, and careful attention should be given to the mixed sore of Rollet in order to avoid further skin complications. The condition of the epitrochlear and postcervical ganglia should be carefully noted, as should also the history of susceptibility to rheumatism, headache, follicular tonsillitis, cephalgia, and all mouth and throat conditions; and all the superficial lymph glands should be carefully examined.

The cases which are particularly apt to be overlooked are those in which the syphilides are manifested by only one or two erythematous spots, the subsequent eruptions being delayed for months, or probably never appearing.

As to treatment, excision was not recommended. The sore should be kept clean, quiet and dry, and iodoform should be employed twice daily after immersion of the organ in hot water for ten minutes. For the treatment of the secondary lesions, the stomach and skin were thought to be the preferable routes of administration, although in selected cases hypodermics and vapors might be used; the author believed that the proper course was to wait for the full development of the disease as signified by the early syphilides, in the interim correcting any gastro-intestinal or nervous conditions. Tobacco, whiskey and champagne must be eliminated. The patient should be warned of his condition and the necessity for strictly following directions, and taking plenty of sleep and careful attention to hygiene.

Hereditary Syphilis.

DR. HOWARD S. KINNE read this paper, in which he stated that the manifestations are usually worse in the first child, thus showing that the tendency to transmission is less as the time goes on. It differs from acquired syphilis in that there is no chancre, nor can the symptoms be classed under distinct periods. The chief differential point is the alteration which inherited syphilis impresses on the nutrition and development, as is evidenced by the fatal marasmus, or acute inflammation of the epiphyses or chronic osteoperiostitis, producing deformity of the bones. The family history should be carefully considered, although the symptoms are varied and usually appear about six weeks after birth, consisting of coryza, erythematous or, in some instances, papular rash, soreness of the corners of the mouth, irritation of the laryngeal mucous membrane, and, unless the infection is very light, marked anemia, interference with the digestion and wasting of the body. Antisyphilitic treatment of the pregnant mother will reduce very materially the chances of the offspring being infected. The child should be carefully nourished, preferably breast-fed, and proper hygienic measures should be observed. Mercury and iodid should not be given unless symptoms require.

Diagnosis and Treatment of Syphilis of the Central Nervous System.

DR. LUTHER C. PETER considered only those conditions which were due to the direct action of the infection and not the symptoms due to organic changes following long after the disease has disappeared, in which he stated that variability in symptoms, absence of systematic grouping of symptoms, paralysis of cranial nerves, Argyll-Robertson pupils, irregularity of pupillary margin, inequality of pupils, apoplectiform and epileptiform attacks, recurring palsies, usually without loss of consciousness, numbness in extremities, increased reflexes, headache, vertigo and altered mental states, are symptoms which point to syphilis of the brain and its coverings. He reported the case of a man aged 39, the disease first developing several years after the appearance of the chancre, commencing with recurring numbness in the extremities, impairment of the bladder function, diplopia, headache, vertigo, difficulty in speech at times, spastic palsy of the left leg, partial palsy of the left arm, Argyll-Robertson pupil, impairment of sensation to the touch. He died six years after coming under observation from pneumonia, and postmortem examination revealed syphilis of the brain and cord and their coverings. The intermittent treatment with potassium iodid and mercury, the latter preferably by inunctions, was recommended, and it was felt that it should be persisted in for several years.

The Recognition and Treatment of Some of the Pharyngeal Lesions of Syphilis.

DR. LEWIS S. SOMERS considered: (1) The erythema; (2) the mucous patch, and (3) the ulceration. Erythema, he believed, was frequently mistaken for catarrhal pharyngitis or tonsillitis, especially in private practice. An examination of the erythema, however, will reveal a copper hue, and a marked tendency of small irregular patches of cloudy swelling to enlarge and present a bluish-white color; this is the mucous patch, the most frequent site of which is on the soft palate, pillars and tonsils, being oval, circular or stratiform in shape. In ulceration, the parts are covered with a thick, mucopurulent, offensive secretion; there is marked tendency to osseous destruction, particularly when the palate is involved. Tuberculosis, lupus, carcinoma and diphtheria may all conflict with this disease, although the former three would usually manifest prominent symptoms in other parts of the body, and the latter can easily be recognized by the presence of the specific organism. Three important diagnostic aids are: history of the initial infection, evidences of the disease in other parts of the body, and the response to specific treatment. Unless one of these is obtained one can not be perfectly sure of the diagnosis. Dr. Somers had obtained the best results in the erythema with proto-iodid of mercury in one-fourth to one-third grain doses two to three times daily; the disappearance of the congestion being accelerated in occasional cases by an astringent gargle. The same form of mercury, aided in some cases by the application of 20 to 50 per cent. solution of nitrate of silver, locally in some cases, and in others by the local application of a solution of chromic acid, has given the best results.

Syphilis of the Eye.

DR. WENDELL REBER said the most usual site for the primary sore is at the margin, or just without the margin, of the lids. The secondary phase is most frequently in the uveal tract. Records show 50 per cent. of all cases of iritis to be specific; this fact he believed was sufficient ground for suspecting every case of iritis until trauma, tuberculosis, microbic infection or the rheumatic diathesis has been shown to be causative. Choroiditis is as frequently of specific origin as iritis and is a valuable adjunct to diagnosis. The most frequent tertiary involvement are the intra-ocular and extra-ocular palsies, and these conditions, in the absence of diabetes or trauma, are usually of specific origin and the forerunners of locomotor ataxia or general paresis.

DISCUSSION.

DR. F. SAVARY PEARCE felt that the presence of diplopia should always be suggestive of specific disease, especially when in conjunction with headache, which is usually worse at night and with increased reflexes. The reflexes are usually out of all proportion to the spasticity, which is due to the fact that the tertiary symptoms encroach on the nerves and irritate the motor cortex of the brain without destruction.

DR. A. BERN HIRSH believed that the patient, when apparently cured, should be instructed to inform any physician who might in the future treat him for a return of such symptoms that so many years ago he had had similar symptoms.

DR. S. L. GANS felt that the physician was sometimes misled by the patient's social standing; he directed particular attention to the necessity of recognition of slight throat lesions.

DR. L. C. PETER felt that as good results could be obtained from small doses of potassium iodid as from the larger ones. Nervous syphilis he believed occurred within six months after the initial lesions, although there are exceptions, one of which had come under his notice in the case of a man suffering from hereditary syphilis, who was entirely free from symptoms from 6 to 45 years of age, at which time he had severe meningitis and cerebral ataxia.

DR. LEWIS S. SOMERS called particular attention to the necessity for impressing on the patient the exceedingly infectious character of the disease, and emphasized the value of tonic treatment in addition to the specific remedies.

Drs. Frank White, William H. Good, L. Sharp, A. Bernheimer and Carl Lee Felt also took part in the discussion. Cases were reported to show the obscurity of the syphilitic factor.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Eczema of the Eyelids.

Brocq, in *Med. Press*, recommends, in the treatment of eczema of the eyelids, first a dietary excluding wine, alcohol, pork, cheese, fish and spicy food. Laxatives and cod-liver oil are advised in the general treatment. Locally he applies compresses of a warm boric acid solution morning and evening, after which the following application is applied locally:

℞. Zinci oxidi
Pulv. amyli, āā 3iiss 10
Lanolini
Vaselini, āā 3iv 15

M. Ft. unguentum. Sig.: Apply locally. After the inflammatory period has subsided the following ointment is applied:

℞. Ung. hydrarg. oxidi flavi ..... gr. x 65
Liq. petrolati 3vi 25

M. Ft. unguentum. Sig.: Apply locally night and morning.

Barber's Itch.

The following combinations are recommended by *Merck's Archives* in the treatment of barber's itch:

℞. Resorcin 3i 4
Glycerini 3ii 8
Ung. aq. rosæ q. s. ad 3ii 60

M. Ft. unguentum. Sig.: Apply locally several times a day, first removing the crusts with sweet oil; or:

℞. Naphthol resublim. 3ss 2
Saponis mollis
Cretæ prep.
Sulphuris loti
Lanolini, āā 3iii 12

M. Sig.: To be applied on the face at bedtime.

Furunculosis.

In furunculosis the same author recommends strong purging by administering a glass of some mineral water daily for three or four days, when a teaspoonful of fresh beer yeast is ordered given in teaspoonful doses before each meal in a glass of water. This should be continued for eight days.

Wine, alcohol and pork must be excluded from the diet. If the digestive tract is in good condition, cod-liver oil, arsenic and iron may be given with benefit. Locally an effort should be made to arrest the development of the boil by the application of the tincture of iodin or lint moistened with spirits of camphor or a mixture of both in equal parts. The following has also been recommended:

℞. Iodi 3i 4
Acetone 3iii 12

M. Sig.: The boil should be touched lightly with this mixture and usually it is dried up the following day. This preparation is very caustic and should be applied with care.

Gastric Neurasthenia.

Blackburn, in the *N. Y. Med. Times*, recommends, in the treatment of gastric neurasthenia, physical rest, specific instructions to the patient as to hours for sleep and for rest during the day and a demand that they be closely followed. Patients should be warned against overexercising.

The Weir Mitchell rest treatment may be instituted for a time, but as a rule is not necessary in the gastric form. Hydrotherapy in the form of sponge, shower or cold douche in the morning is of service. The diet should be nourishing and non-stimulating. As to the medicinal treatment, he recommends proper elimination, the relief of constipation by a laxative containing aloes. As a tonic he recommends the syrup of hypophosphites with strychnia. One of the following combinations may be of service to relieve the constipation in such cases, as recommended by *Rev. Française de Med. et de Chir.*

℞. Tinct. gentianæ
Tinct. calumbæ, āā 3i 4
Tinct. nucis vom. 3ss 2

M. Sig.: Twelve to fifteen drops in water before each meal; or:

℞. Pulv. nucis vom. .....gr. ss 03
Ext. gentianæ .....gr. iss 09
Pulv. gentianæ q. s.

M. Ft. cap. No. i. Sig.: One such capsule once or twice daily.

Alcoholic Excess.

The following combination is recommended by O. H. Snider, in *Med. Bulletin*, in the treatment of excessive use of alcohol followed by extreme depression, irritable nervous system and cerebral disturbances:

℞. Sodii brom. 3ii 8
Ext. hyoscyami flu.
Ext. lobeliæ flu., āā 3i 4
Ext. pulsatillæ flu. .....gtt. xx 1 30
Ext. lupulini flu. 3ii 8
Aquæ menth. pip. q. s. ad .....℥ii 60

M. Sig.: One teaspoonful and repeat in four hours if necessary. The patient must be given rest and comfort. During convalescence strychnia or nux vomica should be given with the bitter tonics.

Administration of Digitalis.

In an abstract in *Ther. Gazette*, Barié of Paris points out errors which may be committed in giving digitalis without having first thoroughly cleansed the digestive tract. He therefore recommends a purgative such as the compound jalap powder in preference to castor oil or salines previous to administering digitalis. He also emphasizes the importance of absolute rest in bed and a milk diet. In some cases the presence of edema and ascites and effusion into the pleural cavity is such an obstacle that the digitalis can not have much effect until the excessive venous pressure is relieved. Under such circumstances venesection should be performed, removing about 300 grams to relieve the stasis. He also states that digitalis should not be begun in large doses when tricuspid insufficiency is present, as this is a sort of safety valve. Aged persons and those suffering from arteriosclerosis are to be given digitalis with care as the kidneys are apt to be deficient and the arteries bad. It should never be given to patients suffering from anemia, dyspepsia, Basedow's disease, tuberculosis in its initial stage or to those who are addicted to smoking. It should never be used in aortic insufficiency in its initial stage owing to the fact that it increases the length of diastole. Such drugs as opium, the iodids, alcohol, and tannic acid should not be used at the same time with digitalis.

Antiseptic and Cleansing Sprays.

The following combinations are recommended by Shurly in his "Dis. of Throat and Nose":

℞. Sodii benzoatis .....gr. v 30
Acidi carbol. .....gr. i 06
Glycerini 3i 4
Aq. destil. 3vii 28

M. Sig.: To be used in the atomizer as an antiseptic spray.

In all forms of acute coryza the following is recommended:

℞. Sodii benzoatis .....℥ss 15
Aq. calcis .....℥viii 240

M. Sig. As a nasal spray or douche.

In syphilitic lesions and ulcerations the following is of service:

℞. Hydrarg. bichloridi .....gr. i 06
Aq. cinnamomi .....℥viii-xvi 250.-500

M. Sig.: Locally to the pharynx and larynx.

As an astringent to the throat the following is advised:

℞. Sodii bicarb. .....gr. xxv 1 65
Ext. hamamelidis destil. .....℥i 30
Aq. destil. .....℥v 150

M. Sig.: As a cleansing and astringent spray.

As an anodyne the following:

℞. Menthol .....gr. i 06
Alcoholis .....m. v 30
Calc. phos. precip. .....gr. v 30
Aquæ q. s. ad .....℥ii 60

M. Sig.: Locally as an anodyne.

The following containing alumnol is serviceable as an astringent and anodyne to the tissues of the throat:

℞. Cocainæ .....gr. v 30
Alumnol .....gr. x 65
Aquæ menthol .....℥i 30

M. Sig.: Locally as an astringent; or:

℞. Menthol .....gr. v 30
Glycerini .....℥ii 60
Cocainæ .....gr. xx 1 30
Aquæ .....℥ii 60

M. Sig.: Locally as an astringent and anodyne.

Vomiting During Administration of Chloroform.

According to Stuver, in *Denver Med. Times*, painting the mucous membrane of the nares with a 2 per cent. solution of cocain will prevent, in the majority of cases, the vomiting which so frequently accompanies chloroform anesthesia. He has employed this method in about twenty cases with splendid results. In several of the cases in which the patients had suffered a great deal from vomiting during previous operations, this method had prevented all such symptoms. He applies the solution thoroughly to the mucous membrane by means of a cotton-wrapped applicator, ten or fifteen minutes before starting the anesthetic. The cocain inhibits the reflex action and irritation of the stomach which, if present, frequently inhibits the heart's action. According to the author observations have been made which show that irritation to the nasal mucous membrane may affect the heart's action through irritation of fibers of the pneumogastric, consequently by the above procedure the danger of cardiac and respiratory failure, as well as shock, are decidedly lessened.

Medicolegal.

Keeping Registry of Births and Deaths Without Pay.—Sections 2582 and 2583 of the Kentucky Statutes of 1899 make it the duty of all physicians, surgeons and midwives to keep a registry of all births and deaths which they have professionally attended, and to report them to the county clerk. In the case of Commonwealth vs. McConnell, where there was an indictment for non-compliance with these requirements, it was urged that the statute was unconstitutional because

it required physicians to perform a service without compensation, and that the legislature had no power so to do. But the Court of Appeals of Kentucky does not think the statute unconstitutional on that ground and affirms that the legislature has authority to require said duties.

Minnesota—Restricts Commitment of Harmless Insane.—Chapter 106 of the Laws of Minnesota of 1903 provides that no harmless person, who can not be benefited by hospital treatment, shall be committed to any hospital for the insane merely because he is suffering from idiocy, epilepsy, imbecility or infirmity of old age. Every jury appointed to examine an alleged insane person, in addition to the facts by law required to be ascertained, shall ascertain and determine whether or not such patient can be benefited by hospital treatment. The superintendent of any hospital for the insane, with the approval of the board of control, may at their discretion discharge or parole any inmate of such institution who is capable of caring for himself or can be cared for by relatives, and who is not dangerous to himself or the community.

Minnesota—Puts Check on Compulsory Vaccination.—Chapter 299 of the Laws of Minnesota of 1903 provides that hereafter it shall be unlawful for any board of health, board of education, or any other public board or officer, acting in the state under police regulations or otherwise, or under any general law or city charter however adopted, to compel or require the vaccination of any child, or to make vaccination a condition precedent to the attendance at any school in the state, or to exclude any child or other person from attendance on any school on account of such child not having been vaccinated; except that, in epidemics of smallpox, such boards of health and boards of education may, by joint action, require such vaccination by a duly licensed and practicing physician, to be selected by the person to be vaccinated; provided, that any child may be exempt from the provisions of this act where a reputable physician certifies in writing that on account of said child's physical condition such vaccination would be dangerous to the child's health.

Minnesota—Establishes Sanatorium for Consumptives.—Chapter 316 of the Laws of Minnesota of 1903 provides for an advisory commission of five physicians (one a homeopath) and the establishment of a sanatorium for consumptives near Walker, in Cass County. The commission shall appoint in each county from one to three reputable physicians who shall examine on the presentation of orders from the superintendent of the sanatorium all persons applying for admission and determine whether such persons are suffering from incipient pulmonary tuberculosis, and forthwith report the result of such examinations to the superintendent of the sanatorium. Only persons suffering from incipient pulmonary tuberculosis shall be received as patients in the sanatorium. One of the prescribed duties of the superintendent shall be to oversee and secure the individual treatment and personal care of each patient while a resident in the hospital and to keep a proper oversight of all inhabitants thereof. He must also maintain a salutary discipline among all employes, patients and inmates and enforce strict compliance with his instructions and obedience of all rules and regulations; he must cause full and fair accounts of the conditions and prescriptions of the patients to be kept regularly from day to day in books provided for that purpose. The inmates must pay when able to do so, but any person unable to pay the charge for support determined by the board of control may be admitted on the request of the county commissioners of the county whereof such person is a resident, and the charges for the board of such person shall be paid by such county.

New Mexico—To Encourage Establishing Sanitariums.—Chapter 17 of the Laws of New Mexico of 1903 provides that any company or corporation which shall, within one year from the passage of this act, commence and within two years after the passage of this act shall have expended at least $100,000 in the construction of a sanitarium in New Mexico for the care of invalids and persons with tuberculosis and other pulmonary diseases, shall thereafter be exempt from taxation on all property actually used in connection with such sanitarium for a period of six years after the expiration of two years after the passage of this act.

New York—Ban on Careless Distribution of Medicines.—Chapter 494 of the Laws of New York of 1903 provides that any person, corporation, etc., who distributes or causes to be distributed, any free or trial samples of any medicine, drug, chemical or chemical compound, by leaving the same exposed on the ground, sidewalk, porch, doorway, letter boxes, or in any other manner, that children may become possessed of the same, shall be guilty of a misdemeanor, etc.

New York—Requires Consents for Tuberculosis Camps.—Chapter 638 of the Laws of New York of 1903 provides that a hospital camp or other establishment for patients with pulmonary tuberculosis shall not be established in any town unless the board of supervisors of the county, and the town board of the town, shall each adopt a resolution authorizing the establishment thereof, and describing the limits of the locality in which the same may be established.

New York—Creates Office of Medical Inspector.—Chapter 221 of the Laws of New York of 1903 amends Section 4 of Chapter 545 of the laws of 1896, by providing that the commission in lunacy may appoint a medical inspector, who shall be a well-educated physician, a graduate of an incorporated medical college, and who shall have had actual experience in an institution for the care and treatment of the insane. Such inspector shall receive an annual salary of $3,500, and traveling expenses. He shall, subject to the direction of the commission, inspect the state hospitals and other institutions for the insane which are subject to the supervision or visitation of the commission, and shall make an examination, so far as circumstances may permit, of the patients therein confined, especially those admitted thereto since his preceding visit, giving such as may request it suitable opportunity to converse with him apart from the officers and attendants. He shall perform such other duties as may be prescribed and directed by the commission.

North Dakota—Prohibition on Distribution of Drugs.—Chapter 81 of the Laws of North Dakota of 1903 provides that any person who shall by himself, his servant or agent, or as the servant or agent of any person, leave or deposit on the doorstep or premises owned or occupied by another, or who shall deliver to any child under 14 years of age, any patent or proprietary medicine or any preparation, pill, tablet, powder, cosmetic, disinfectant or antiseptic, or any drug or medicine that contains poison or any ingredient deleterious to health, as a sample, or in any quantity whatever for the purpose of advertising, shall be deemed guilty of a misdemeanor. The terms used in this act shall include all remedies for internal or external use, either in packages or bulk, simple, mixed or compounded.

1 *Experiments to Determine the Value of Formalin in Infected Wounds of the Eye. J. H. Claiborne and Edward B. Coburn.
2 *"The Heart Cure"; Its Terminology, Purposes and Achievements. Including the Etiology of Fatty Degeneration. Homer Wakefield.
3 *The Relation of Mild Types of Diphtheria to the Public Health. Thomas W. Salmon.
4 *Chronic Villous Arthritis, with Special Reference to Its Etiology and Pathology. (Continued.) Charles F. Painter and William G. Erving.
5 Eclampsia Hemorrhagica. Report of a Case. Ralph W. Lovenstine.
6 Who May Benefit by Altitude Treatment? J. N. Hall.

1. **Formalin in Infected Eye Wounds.**—The experiments of Claiborne and Coburn were made on rabbits' eyes, and are reported in detail. They find that formalin, 1 to 500, can be injected into the vitreous of rabbits without producing more than momentary disturbance. It is possible to cause panophthalmitis and destruction of the eyes by injecting 3

minims of a turbid solution of streptococci into the vitreous. It is also possible to produce the same result by infection in the ciliary region caused by penetrating wounds with infected pointed instruments. Infections of the vitreous and ciliary region do not necessarily cause destruction of the eye. At times the inflammatory symptoms gradually subside and the eye recovers spontaneously. Formalin, 1 to 1,000, when injected into the vitreous has no influence on streptococcus infection. The results of these experiments warrant the treatment of commencing infections of the eye by injections into the capsule of Tenon of 1 in 1,000, or even 1 in 500, formalin solution.

2. **"The Heart Cure."**—This method, which is not properly designated as the Nauheim or Schott method in Wakefield's opinion, is described at length. He first considers the pathologic conditions, and holds that the two principal degenerations of heart disease, namely, gelatiniform and fatty metamorphosis, are entirely due to and dependent on suboxidation from cardiac and blood deficiencies, and are preventable, arrestable and restorable in the great majority of cases. His own plan of treatment is to restore oxidation and to lighten the heart's load and clear out the vascular system. He uses oxygen by free inhalation through a tube of an abundance of nascent oxygen gas, or the whole atmosphere of a small room is impregnated with it. He administers iron and enemas of a 50 to 100 per cent. saturated solution of sodium bicarbonate, sometimes adding hydrogen peroxid, all at a temperature of blood heat. He always gives glycerophosphates or phosphorated oil internally. To clear out the portal and vascular system in general he uses very small doses of calomel and a saline cathartic, supplemented by warmth to the extremities and drinking cold water between meals. But the restoration of oxidation is by far the best remedy for the clearing of the circulation, the relief of resistance to arterial flow and consequent relief to the heart. He finds that a teaspoonful dose of hydrogen peroxid every three hours has restored the twenty-four-hour urine to about 50 ounces in cases of serious anuria, where one-twenty-fifth-grain doses of nitroglycerin had singularly failed. He has repeatedly promptly arrested cardiac hemorrhages with immediate inhalations of nascent oxygen gas and, combined with soda colon injections, they have promptly controlled and entirely reduced marked thoracic and abdominal dropsies. As the patients improve he gives light frictional brushings and massage, and begins the bath treatment by immersing the feet in a carbonic acid or a capsicum bath. He thinks the real secret of the bath cure lies in its physiologic effect as a cold bath, and that carbonic acid and alkalies simply counteract the cold by stimulation. Among the drugs, he specially mentions ergot and adrenalin in well-adapted cases. The last one, however, is dangerous for careless prescribing. Arsenic, phosphates, lead, etc., even mercury in large doses, are contraindicated. For beverages he disbelieves in the free administration of liquor, but when not continuously given it is a valuable stimulant for emergencies. He often institutes the full bath before the patient is able to walk to and from the baths or from one room to another. In using the glycerophosphates he warns against proprietary preparations containing an abundance of alcohol and sugars.

3. **Diphtheria.**—Salmon calls attention to the occurrence of catarrhal diphtheria, as he calls it, in which there is no false membrane. He urges the necessity of its isolation.

4. **Chronic Villous Arthritis.**—Painter and Erving's article is continued with reports of cases. The etiology is also discussed; trauma, infections, diathetic conditions, etc., and the clinical history described. The treatment varies with the cause. Very many of the early cases when caused by pronated or flat foot, where the condition in the knee joint is that of a passive hyperemia due to the malposition, are promptly and permanently cured by appropriate support, adhesive plaster strapping, etc. Where due to diathesis such treatment is only palliative and in these cases where it fails operative measures should be taken. The technic of the operation is described. (The article is to be continued.)

Medical Record, New York.

November 21.

7 *Traumatic Locomotor Ataxia. Allan M. Hamilton.
8 *Intravenous Injections of Colloidal Silver in the Treatment of Erysipelas. Warren Coleman.
9 Chronic Cyanosis of the Extremities Associated with Polycythemia and Splenomegaly. Joseph Collins.
10 *The prognosis and Treatment of Chronic Deafness. Philip D. Kerrison.
11 *Internal Administration of Ichthyol in Pulmonary Affections. Maurice Rosenberg.
12 An Extreme Case of Bradycardia. L. E. Norfleet.

7. **Traumatic Locomotor Ataxia.**—The conditions here described are chiefly the hysterical results of traumatism though other conditions are recognized as possibly suggesting permanent injury in the posterior columns. Hamilton also relates cases of traumatic neuritis with recurrent hyperemia and pressure, and cases illustrating different types of pseudotabes.

8. **Erysipelas.**—Coleman reports 5 cases of erysipelas treated by intravenous injections of colloidal silver. The method is harmless, and he describes the technic. He uses a hypodermic needle and injects as near as possible in the long axis of the vein, if necessary withdrawing a little blood to be sure that it is properly inserted, avoiding all chance of introducing air. The contents of the syringe should be injected slowly and none allowed to escape into the tissues where it would produce burning pain which might last for hours. He injects 5 to 10 c.c. of 1 per cent. solution. While not venturing to draw conclusions too positively, he is convinced from his experience with some 20 cases of the harmlessness of the method, and recommends it in appropriate conditions. If the injections do not benefit the patient, he says, they will do no harm.

10. **Chronic Deafness.**—Kerrison notices the various forms of chronic deafness due to tubal catarrh, hypertrophic catarrh, suppurative processes and chronic hyperplastic otitis. He concludes that there are certain cases of advanced catarrhal deafness, even without evidence of serious labyrinthian involvement, that do not respond to treatment, but that in a large proportion of cases the power of audition can be distinctly improved. In the early stages of catarrhal or tympanic deafness the majority of cases are susceptible to practically complete cure. In the advanced stages of catarrhal deafness rational treatment often results in improvement, which adds to the pleasures of life, though the normal hearing power may never be regained. Where a slight improvement of hearing is brought about, the result is often of value to the patient in arresting a process that may otherwise lead to pronounced or total deafness.

11. **Ichthyol in Pulmonary Affections.**—Four cases are reported by Rosenberg, who administers the drug in water, never in capsules, giving it before meals. In no case was there any digestive disturbance except a slight diarrhea, with some eructation, which stops when the patient becomes accustomed to the drug. He finds it increases assimilation, improves nutrition, checks pain, increases the body weight and acts as a germicide against the tubercle bacillus. Though he does not put it before the profession as a specific, he has found that much good can be derived from its use.

New York Medical Journal.

November 21.

13 *Ocular Headache and Other Ocular Reflexes; a Statistical Study. (To be continued.) M. W. Zimmerman.
14 *A Clinical Study of the Use of Antitoxin Serum (Dunbar's) in Hay Fever During the Season of 1903. A New and Distinct Advance in Its Management. Alexander W. MacCoy.
15 *The Treatment of Acute and Subacute Anterior Gonorrhea by Retrograde Injections of Stronger Solutions of Silver. (To be continued.) Hermann G. Klotz.
16 *The Early Operative Treatment of Tuberculous Osteitis of the Knee. (To be concluded.) Bernard Bartow.
17 Brain-fag, and Its Effects on Health. John Knott.
18 The Course and Diagnosis of Variola.—Based on Its Last Outbreak in New York City. William L. Somerset.
19 *The Effect of Lemon Juice in the Mixture Known as Lemonade on Typhoid Polluted Water. William G. Bissell.

13. **Ocular Headache.**—Zimmerman has investigated optical errors as related to the production of headaches, and gives the results. In 1,000 private cases he found frontal headache in 279; no details in 257, and small numbers with headaches localized elsewhere. In 1,000 hospital cases the proportion

of frontal headache was still greater, being 391. The similarity between the two series was very marked. As regards the conditions of sight and muscular errors, he found hypermetropic astigmatism to predominate in the production of headaches or co-exist with such. In 277 cases of heterophoria without headache there were 129 cases of hypermetropic astigmatism with small numbers of other types. In heterophoria with headache the hypermetropic astigmatism occurred in 356 out of 550 cases. (The paper is to be continued.)

14. **Hay Fever.**—MacCoy has used Dunbar's serum and reports 6 cases. In a total of 15 cases with which he experimented the effect was promptly manifested and relief complete. They appeared to confirm the contention of Professor Dunbar that cases of hay fever are dependent on toxins resident in the pollens of various grasses. MacCoy thinks this opens up a new field in serum therapy, being, as far as he is aware, the first instance of the production of antitoxin serum or fluid where the animal product has been crossed with the vegetable product.

15. **Gonorrhea.**—Klotz has employed deep injections of silver solutions, passing the injection syringe back to the bulbar region and there injecting from a side opening in the nozzle, and gradually withdrawing it, the meatus being closed. After two minutes or more the fluid is allowed to escape, and usually another syringeful is injected. Finally, some absorbent cotton is placed in front of the meatus to absorb the excess. The burning sensation produced is of short duration. An increased discharge appears, almost cheesy looking, which diminishes or disappears after ten to twelve hours. At this time the patient begins in the usual way to use some of the common antiseptic or astringent solutions. If an increase in the discharge appears in four or five days the silver injections should be repeated, usually in stronger solution than at first, and in this way the treatment is continued. Finally, a test of the effects of beer and whisky is allowed. He has been surprised with the good results in some of these cases. As to the solutions used, he has tried ichthargin, argentamine, albargin, protargol and argonin. After an extensive trial he has been very well satisfied with albargin which acts mildly and is clean. He uses a strength of from 1 to 5 per cent. He finds that, after all, the solutions of nitrate of silver have sometimes proven most reliable, the more so the longer the disease has lasted. (The article is to be continued.)

16. **Tuberculous Osteitis of the Knee.**—The method advocated by Bartow is an operative procedure, trephining the condyle in the suspected locality and removing any local focus of infection, followed by a correction of the knee malposture. The employment of this operation when tuberculous osteitis has advanced too far has led to a discrediting of its value. The presumed impossibility of locating the focus, with the possible presence of multiple foci, have also had their effect. He thinks, however, from his own experience, that the method deserves further employment. (The paper is not completed in this issue.)

American Medicine, Philadelphia.

November 21.

20 *The Treatment of Surgical Shock by Adrenalin. Edward Martin and M. E. Pennington.
21 Nine Cases of Resection of the Intestine. George Tully Vaughan.
22 A Unique Case: Molluscum Fibrosum of the Rectum in a Patient with the Typical Skin Lesion. A. B. Cook.
23 *Growth and Development of Children in Colorado. Charles F. Gardiner and Henry W. Hoagland.
24 The Use and Abuse of Fresh Air and Over-feeding in Tuberculosis. W. H. Prioleau.
25 A Consideration of General Anesthesia with a Presentation of Instruments. Frederick Griffith.
26 The Influence of the University of Maryland on Medical Education. John C. Hemmeter.

20. **Adrenalin in Surgical Shock.**—The action and outcome of adrenalin in the system is discussed by Martin and Pennington, who report the results of experiments and also 5 instances of the clinical use of the drug in shock. All the cases were practically moribund, and there was not one in which there was a fair chance of recovery. The clinical evidence is therefore inconclusive. Laboratory experiments apparently show that the intravenous injection of adrenalin is the most powerful, practicable cardiac and vasomotor stimulant yet presented to the profession. It also stimulates the respiratory center and increases metabolism and body temperature, but it is inert so far as its systemic effect is concerned when given either by the mouth or by the rectum on account of its rapid alteration in the body. The toxic dose for man is not known, but is probably over a hundred times greater than that usually employed. The dilution, on account of the tendency to abscess formation, should be at least 1 to 10,000 when given hypodermically, but he thinks it is safe to give an initial dose of 10 c.c. of 1 to 1,000 in 90 c.c. of normal salt solution. In cases of urgency adrenalin chlorid should be given intravenously in a dilution of 1 to 10,000, injected slowly to prolong the effects of the drug, and should be pushed up to 100 c.c. of the strong solution or until the heart clearly and unmistakably responds. As yet there is no convincing clinical proof that it is as efficacious when used on man as laboratory experiments would lead us to believe. On account of its power of lessening the bacteriolytic power of the blood of animals, its use in cases of infection in the human should be with great caution until wider experience has proven its safety or danger.

23. **The Development of Children in Colorado.**—Gardiner and Hoagland have tested the lung capacity and respiratory movements of children at Colorado Springs as compared with those of Chicago, St. Louis and other Eastern cities; also the growth at various ages, chest measurements, average weight, etc. They find that there is a climatic factor in Colorado that favors the development. Native-born Colorado children are taller and weigh more, as well as have greater respiratory capacity than those of Eastern cities.

27 *Observations on the Effect of Catheter Drainage on the Function of the Kidneys in Interstitial Nephritis and Pyelonephritis. Arthur T. Cabot.
28 *Unclean Milk, Bovine Tuberculosis and the Tuberculin Test—Their Relation to the Public Health. (To be continued.) E. R. Larned.

27. **Catheter Drainage in Pyelonephritis.**—Cabot has treated a certain proportion of his cases of kidney disorder connected with prostatic obstruction by the installment of permanent catheter drainage, the urine being removed as rapidly as it flows in. The relief of pressure, he thinks, extends even through the uriniferous tubules into the malpighian bodies. He puts a soft catheter into the bladder and arranges it so that it draws the urine steadily without irritating the vesical walls. It should be watched so closely as to insure that it shall never stop running for more than a few minutes at a time. This is no new method for bladder trouble, but he has not seen it mentioned for kidney troubles. The only explanation for the good effects on the kidneys that he has observed is that the ureters gradually contract somewhat when internal pressure is relieved, and the bladder being no longer stretched, its muscular coat recovers its tone and restores the valvular condition at the ureteric orifice. He gives water freely at the same time, and has noticed a decided increase in the quantity of urine passed. His conclusions are that the relief of tension in kidneys which, owing to long obstruction, are exhibiting the clinical phenomena of interstitial nephritis, usually brings about a return of normal function, thus indicating that the renal condition is directly due to the obstruction and increased tension. It seems probable that with dilated ureters, permitting regurgitation of urine into the kidney pelves, long drainage of the bladder will permit such a shrinkage of the ureters and ureteral orifices as to restore the normal valvular action of the ureters, and the retro-flow of urine will thus be stopped.

28. **Milk.**—Larned advocates all the precautions to insure pure milk, free from infections, the use of the tuberculin test to eradicate tuberculosis in herds, and careful milk inspection in cities. He has made cultural experiments in the city of Joliet and finds no samples entirely satisfactory. He notices the improvement in the milk supply of Chicago owing to the efforts of the department of health of that city.

39 Report of Observations Made in the Clinic of Dr. J. Babinski, Paris. With Special Reference to Some New Aids in the Diagnosis and Treatment of Nervous and Mental Disease. Charles Gilbert Chaddock.

33. **Acute Delirium.**—Tomlinson describes cases and discusses the pathology of the condition. He holds in substance that it is due to an exhaustion, only differing in degree and the fact that it is based on intoxication from the normal fatigue conditions. The disintegration in either case, he says, is the result of an excess of activity of the cell.

34. **The Insane in Penal Institutions.**—Robertson thinks that the earlier recognition of the insane in penal institutions would prevent the turning out on the public of a class of degenerates that are a peril to society. He asks how the recognition of the insane in penitentiaries can be thus made a factor in the diminution of crime, and answers it: (1) By the establishment in every state of separate institutions for the insane and defective who exhibit criminal tendencies, where they can be held in custody until a competent medical tribunal shall determine that they are fit to return to society. (2) By examination by competent alienists, prior to sentence by court, of those accussed of crime, the report of the physician to be laid before the court to assist in reaching a proper determination of the case. (3) The appointment on staffs of all penal institutions of competent alienists, whose duty it shall be to recognize and secure the transfer to hospitals of those so markedly defective as to require such treatment. If it is not practicable to appoint an alienist for each institution he suggests that one be appointed in each state whose duty it shall be to visit and inspect the inmates of the penal institutions. The warden or officer in charge of such institutions should keep a careful record of each prisoner known to show any mental peculiarities, and furnish information to the alienist on each visit. We should not attempt in our social organization to make the punishment fit the crime, but should study each prisoner to seek out those who should be treated as defectives apart from those who should be treated according to the old lines in state penitentiaries, or those believed to be susceptible of improvement by means of the more modern treatment afforded by the reformatory.

35. **Insanity in Connecticut.**—The summary of Burr's article is given as follows:

A study of the histories of 7,657 cases of insanity covering a period of thirty two years may be summarized briefly in the following general observations: 1. The ratio of the insane to the general population is much larger than most statisticians have estimated it to be, but the increase in the proportion of the insane is very much smaller than has been determined heretofore. 2. The foreign element of our community shows much the larger proportion of insane than does the native. The native insane, however, have increased to a considerable extent, but not in the same proportion as the foreign insane. 3. The cities show a much larger percentage of insane than do the counties, but the counties show an increasing proportion of insane in the later years. 4. We have also seen that the large proportion coming from the cities is due to the larger percentage of the foreign element in the city, also that with increase of the foreign element in the country there is an increase in the insane. 5. The Irish show the largest percentage of the insane. The Germans are next in proportion. The native Americans show the least insane to population. In general the middle period (1880-1890) shows the largest proportion of the foreign insane. 6. In proportion to population the Irish lead all other nationalities in the production of insanity. 7. The cities, as a whole, send much larger numbers of foreign insane in proportion to the population than the counties. 8. As compared with the whole state, Hartford and New Haven have larger proportions of foreign insane than the cities, as a whole, over the counties of the state. 9. Fairfield, Litchfield and Windham counties show the lowest proportion of native insane.

36. **Non-Dementing Psychoses.**—Dana's article is explained in its title. The patient was one in whom an absolute arrest was observed in the course of a distinctly degenerating insanity, and he considers the report as of value on account of the psychic methods and examinations made at three different periods of time. He thinks they can be applied in other cases where a positive prognosis is desirable. The account is interesting, and it would appear that there had been absolutely no change in the man's condition between the last examination and that of three years previously.

43 Hypophosphites of Calcium, Sodium and Potassium in the Prevention and Treatment of Abscess. Sinclair Tousey.

40. **Bright's Disease.**—Gordon has studied the surgical treatment of Bright's disease, and concludes that it is primarily an acute inflammation of the kidney structure, not dependent on any specific infective germ. If early recognized and properly treated it will terminate by resolution. But if neglected or not recognized, repeated acute attacks may occur, each one leaving products of the inflammatory process, which may organize or even suppurate. The acute attacks are always short, but leave more or less products which interfere with the circulation, finally producing a chronic passive congestion. The result of these attacks is an enlargement of the organs, causing pressure of the fibrous capsule. Complete decapsulation relieves this pressure, depletes the distended vessels by more or less bleeding, and allows the circulation to resume its normal conditions and absorb the exudate. Even when one kidney alone is involved, operation on that kidney may relieve the symptoms. The surgeon is justified in operating in advanced cases when the suffering is great, simply to relieve this.

45 The Necessity for an Early Diagnosis in the Prevention of Deformities. Reginald H. Sayre.
46 A Case of Stammering Treated by Hypnotism. G. Hudson Makuen.

44. **Tuberculosis in the West.**—Bullock gives his experience as a health seeker, and as a physician in New Mexico and adjoining regions. He thinks the accommodations in most places are comparatively poor. There are a number of excellent places open to individuals, but they are generally expensive. Everywhere one is impressed with the fact that individuals are doing what they ought not to do for their health. The climate is expected to do everything. One of the first lessons he drew from his experience was that most patients are disappointed for this reason. The majority of patients are past the point when climate could be an aid to them. There are undoubtedly many old chronic cases who live long and useful lives in this western country, and there are a great number of genuine cured cases who illustrate the best results. There are also the climate seekers who go traveling around and vary their residence with every season; he would not send a patient to a place where conditions were only propitious part of the year. He would not send a tuberculous patient to a city in search of health. He criticises the early management of the Government Sanitarium at Fort Bayard, where he served as pathologist for a season. Changes in authorities and so on have been unfavorable to the best management, and a large proportion of the cases are not hopeful at the start. He analyzes the experience there as he observed it, and remarks that while there he was in a position to obtain conclusive evidence that the tuberculin test is not a justifiable procedure in the human being; also that it can not be depended

on as completely demonstrating the presence or absence of a tuberculous process. Of the St. Joseph's Sanatorium at Silver City, N. M., of which he is medical director at the present time, he speaks favorably as regards the climate and facilities. He ends with the conclusion that we are not justified in sending patients with a high grade of mixed infection away from home, certainly not across the continent. It is little short of criminal to send one, even of the most favorable class, into the West either to shift for himself under conditions that may prove inimical to his moral as well as his physical welfare, or to bring poverty on those near him. A climate at which an individual may remain comfortably out of doors all the year through and in which the dryness of the air prevents colds and cures a catarrhal disposition; in which the natural healthfulness prevents intercurrent diseases, and in which the altitude checks a hemorrhagic tendency; this for selected cases with little or no mixed infection is the most favorable environment to be found anywhere in the world.

48 The Essential Nature of Reflex Acts and Instincts. A. W. Ives.
49 Eye Clinic at St. Mary's Hospital, Oct. 22, 1903. Eugene Smith.

47. **Exophthalmic Goiter.**—Ballin holds that exophthalmic goiter is successfully treated by operation in about 75 per cent. of cases, and while the mortality from operations has been high, it is reduced in the hands of a skilled surgeon to about 6.3 per cent. or still lower in cases operated on early. The principal dangers are from the anesthetic, hemorrhage and postoperative thyroidism. They can be avoided by local anesthesia, skilled manipulation and the proper preparation of the patient, as well as early operation. The question whether operations on the thyroid are preferable to sympathectomy can not be decided until we have fuller statistics as to the results of the latter operation.

50. **Prostatic Hypertrophy.**—From a general review of the subject the following conclusions are reached by Hawley as regards the problem of prostatic hypertrophy: (1) That it is not the prostate but the adjacent urinary tract that demands relief. (2) That the direct cause of interference with micturition is the displacement of the outlet and floor of the bladder due to enlargement of the retro-urethral portion of the prostate. (3) That until the precise cause of this overgrowth is known and successful preventive measures found we can only hope to relieve by correcting the displacement. (4) That until an effectual method sufficiently safe and simple for application before infection and disorganization of the urinary tract has resulted, surgery can not effectually relieve. (5) That the logical mode of correcting vesico-urethral displacement is by reduction is shown by the fact that operative methods improve urination by virtue of their power to reduce more or less this displacement. (6) While some of these methods partially or sometimes completely accomplish reduction with comparative safety and others entirely reduce the displacement, but at considerable risk, none does so with both safety and success. (7) That since the reduction of the vesico-urethral elevation is essentially a mechanical problem, a reduction based on anatomic and mechanical principles would be the safest and simplest. (8) That the method he describes is based on such reasoning and has received satisfactory confirmation by experimental work. Whether it will prove sufficiently safe and effectual in application, clinical results must decide. In his operation above alluded to, the Zuckerkandl bi-ischial perineal incision was made, exposing the bulb of the urethra and the posterior half of the perineum. The support of the latter was released by dividing the recto-urethral muscle just behind its attachment to the bulb. This enlarged the operative field, allowing the rectum to drop backward. The levators were then divided, still more enlarging the operative field and facilitating exposure, and the prostatic sheath opened under the surface of the prostate from the apex to the base. The sheath on each side was separated from the lateral and under surface of the retro-urethral prostate by the finger (as in prostatectomy). In 2 cases the bladder was opened above, but only to confirm the extent of the reduction of the neck. After freeing the sheath, the prostate was dislocated downward, and in each case the reduction of the elevated neck of the bladder was very plain but insufficient. In each case sections were removed from the outer and lower portion of each lateral lobe, resulting in still greater reduction. In one case where enlargement was almost entirely of the middle lobe with marked upward projection of the bladder floor, the latter disappeared entirely. In each case the reduction seemed complete; the retroprostatic pouch was obliterated and good bladder drainage restored except in one subject where the pouch was large and trabeculated. In each case the urethra, bladder and ejaculatory ducts were uninjured, and enough of the prostate remained untouched to perform its functional purposes in all probability. The steps were easily performed, and the operative damage was slight as compared with prostatectomy with its unavoidable injury of the urethra. The resulting wound was superficial and capable of being made surgically clean. He thinks this method which was tried on cadavers is appropriate in early cases of prostatic hypertrophy before the urinary tract has become infected and disorganized, and while it can be carried out as an aseptic operation.

51. **Fracture of the Mandible.**—The method here proposed by McCurdy consists in drilling through the mandible from the external surface of the bone into the sublingual cavity, drilling between the apices of the second and third teeth from the lines of fracture, when possible, so as to guarantee a firm anchorage for the wires. After the drill holes are made they are threaded with a notched drill. The wire is passed through from without into the mouth on one side, and with the thread through the drill hole on the other side it is drawn out. The two ends of the wire are now drawn out firmly, and the loop on the inside of the bone is molded to the surface of the mucous membrane. The free ends are twisted so as to bring the ends of the bones in perfect apposition. Then the wire is turned up along the remaining teeth, so that the sharp end may not irritate the mucous membrane of the lip. When one side tends to drop the drill holes should not be made on the same plane. In some instances it will require but one hole, the teeth being used for anchorage. This is usually the case in fractures near the angle. He allows the wires to remain in position for six weeks or longer if union has not taken place, and they cause no irritation or sloughing. If necrosis of the bone ever occurred it was too slight to be noticed in his cases. Bandages, etc., are not required. The patient soon learns to hold the teeth together. If infection occurs he uses the ice cap. The mouth should be cleansed with some strong antiseptic, as borolyptol, every hour or so. Before adjusting the fragments the field should be thoroughly cleansed with a 50 per cent. alcohol solution. Iron wire is used, as tougher, less irritating and superior in every way to silver wire. The feeding in the cases where no tooth is missing is by passing a curved glass tube back of the back teeth into the mouth; a fountain or other syringe can be used to force liquids into the oral cavity. In many cases the patient can suck the liquid from a glass with ease. The bulk of the paper is made up of accounts of cases thus treated.

53. **Dislocation of the Ulnar Nerve.**—From the case here reported and a summary of other cases, Cobb concludes that operation for this condition has every chance of perfecting a cure. Only the severe cases, few in number and generally traumatic, need ever be operated on. The operation is only for the symptoms, not for the dislocation, and only in those cases where symptoms are severe and disabling. The steps of the operation are simple and necessarily the same in all cases.

54. **Abdominal Closures.**—The new method here described by Baldwin consists in exposing the bellies of both recti muscles so that they can be brought into direct apposition when the sutures are tightened. Through-and-through silkworm gut is then introduced from within out, the needle being so introduced as to catch merely the edge of the peritoneum, and passed well back through the muscle and fascia and out at a suitable distance from the skin margin. The fascia is next brought together by an over-and-over stitch, using a double thread of coarse silk or cotton. This is introduced so as to give a loop about two feet long. To the end of this loop is attached a wire which is sharply bent on itself so as to be readily drawn through the tissues, the loop being merely a guide. The over-and-over stitch is so passed as to take in about a quarter of an inch of the edge of the fascia and includes no other tissue. It is introduced very loosely so that each turn can be caught later with the finger. As it reaches the end of the incision it is passed from within out through fat and skin so as to make its exit an inch or more above the end of the incision. By means of this guide thread the wire is introduced loosely so that it lies in the wound as a helix, the end of the wire appearing through the skin as the last of the thread is withdrawn. The fascia should be carefully cleaned of fat. A handled needle with an eye at the point is then introduced through the skin and fat about an inch from the other end of the incision, and brought out just above the fascia so as to engage the other end of the wire which is then withdrawn. This needle has been previously passed through two pads about an inch square, made of six or eight thicknesses of gauze. Before withdrawing the wire from the needle one of these gauze pads is slipped down over the wire so as to rest next the skin. The other end of the wire is then threaded through the needle and the other gauze pad placed in position, and a perforated shot placed outside of each pad. The incision is then, carefully dried if there has been any oozing, and while an assistant draws up the ends of the silkworm gut so as to secure apposition of the peritoneum throughout, the wire helix is drawn straight by traction with forceps on each end, care being taken to see that no kinks are formed. The wire should be drawn back and forth once or twice to be sure that there are no kinks. The perforated shot are now pushed down against the pads and clamped. The fascia is thus held in absolute contact. The silkworm gut is then tied as usual, care being taken that it is not drawn too tight, as this is the commonest cause of stitch abscess. If the abdominal wall is enormously thickened from a deposit of fat this method can not be used, since the pressure of the silkworm gut would be too great. In such a case he usually closes the peritoneum, including the transverse fascia, with fine catgut, and the muscle and fascia in two layers with chromicized catgut, No. 1, and then the skin and fat with through-and-through silkworm gut. Gloves are always used in closing an incision in this way. To drain the dead space between the fascia and fat he uses a wick of iodoform gauze, wrapped in gutta-percha tissue, extending from the upper end of the wound through its entire length and brought out at the lower end, introducing it before the silkworm-gut stitches are tightened. Any oozing will be absorbed by this drain which is withdrawn next morning. Where the recti are widely separated, he does not try to bring them together, but takes extra care to bring the fascia together. The line of incision is supported by a many-tailed snug binder of canton flannel. If the case does well the dressings are not removed until the tenth day. Of course, the bandage can be removed at any time. The dressing is then removed and all the sutures withdrawn. The wire is easily withdrawn. A bandage is reapplied and the patient directed to wear it day and night for a month except when bathing, wearing it during the day for a second month. It is not necessary to keep it up longer than the total of three months from the operation.

57. **Pancreatitis.**—Woolsey concludes his paper as follows:

1. In the severe acute cases of pancreatitis, the symptom complex, in connection with some predisposing factor or factors and perhaps some other early signs, renders it possible to make a probable diagnosis. 2. The diagnosis is easier than in the less acute cases. 3. It is only likely to be mistaken for conditions which also require early operation. 4. The finding of fat necrosis at the operation confirms the diagnosis. 5. The treatment should consist of early operation, including infusion for collapse, evacuation and drainage. This may be done under local anesthesia. 6. Extensive or prolonged operations are not justifiable.

59. **Intestinal Suture.**—Horsley's method of intestinal suture here described requires the illustrations to fully explain it. It consists in using a suture that passes through the whole of the intestinal walls, sewing together with a continuous overhand stitch a crescentic area excised, then changing the stitch to a Cushing right-angled continuous suture, penetrating all the coats, and inverting the remaining margins of the wound. When the first knot is reached in the suture it is invaginated and the suture continued by two or more insertions of the needle. With these last two insertions of the needle as secure a hold as possible is obtained without penetrating the mucosa. The very last insertion of the needle is in the inverse direction of the other insertions, so that when the knot is tied it is partially buried. After this suturing is completed scarcely any of the thread can be seen, except a portion of the knot, unless the bowel ends are pulled on. The bowel is then turned to its natural position and the mesentery sewed up with a continuous stitch. He claims that his method is efficient, as shown by experiments on dogs. It requires no complicated apparatus or special mechanical device. It can be quickly performed, is easy to learn and hard to forget.

63 *The Plague in India. A Study of the Results of the Haffkine Prophylactic. B. Rosalie Slaughter.

63. **Plague in India.**—The subjects covered by Slaughter in her paper are the special protective action of the Haffkine prophylactic, which is usually given in India in doses of 5 c.c. or even more. She thinks that the larger dose given there is perhaps the reason for its better success than that of the same material put up at the Hygienic Laboratory at Washington, the dose of which is given as 1 c.c. It has been found that it begins its protective action within twenty-four hours. It is not harmful, even in the incubation stage, and we can set aside Calmette's warning against using it in this stage and inoculate all persons whether they have been exposed to plague or not. The plague serum is harmless, from Indian experience, to those incubating the disease. When a person, however, already has severe headache, tenderness in the glandular region, a temperature of 100 F. or over, its usefulness as a prophylactic is past, because plague has already developed. The reasons for the incomplete success of the English efforts to terminate plague in India are mainly because of the comparatively small area out of an immense population that can be treated, and the fact that villagers neglect the hygienic precautions as soon as their fright is over. The constant pilgrimages and changes of residence, moreover, are decidedly against the extirpation of the scourge. The greater activity and virulence of plague germs at a low, moist temperature has been clearly demonstrated in the Indian experience, and it is a fact worth noting that crocodiles and vultures who feed on plague victims are absolutely immune. The struggle against plague in India is carried on under conditions that we will never be obliged to face in America, but in India the efforts of physicians and their assistants have been successful whenever they have been able to handle small bodies of the people systematically, unhampered by native prejudice. A

number of interesting illustrations of the protective effect of the Haffkine inoculation are reported, showing that it renders a person immune for three months and acts within twenty-four hours of its administration. When given in the incubation stage it has in many cases aborted the disease, but has no effect on other diseases except possibly eczema, which appears to be benefited by it. It confers a high degree of immunity and greatly reduces the number of plague attacks. If in spite of it a person is attacked his chances of recovery are greatly increased.

65 *Fistula in Ano. Walter C. Wood.
66 *Head Injuries: Their Diagnosis. Alexander Rae.
67 *The Treatment of Hemorrhoids in Injections. Arthur H. Terry.
68 A Case of Multiple Lipoma. C. F. Barber.

65. **Fistula in Ano.**—Certain common errors in regard to this disorder are noticed by Wood, such as failure to appreciate the exact pathology of the individual case, the origin of the abscesses, the superficial or the deep nature of the disorder, etc. Tegumentary abscesses are comparatively unimportant, but the subtegumentary inflammations cause a special type of fistula. They are generally lymphatic infections and open externally or just above the mucocutaneous junction and not into the rectum proper. They seldom follow a straight line and are not easily followed with the ordinary probe. He takes exception to the statement of Mathews that it is of slight importance to determine the internal opening of these and other fistulas. Wood remarks that when he finds the internal opening he cures the fistula, and when he does not he sometimes fails. A remnant of the diseased tract continues the infection. In some tubercular cases office treatment may be successful, using cocain and peroxid of hydrogen and following the tract up to its termination, but if the operation is done under anesthesia a much more certain and rapid cure can be obtained by dissecting out the fistula than by incising it. He emphasizes the value of Salmon's back-cut. It is on the same theory that we incise the edge of a chronic ulcer to permit healthy granulations to arise through the indurated tissue. While he favors excision instead of incision in subtegumentary fistulas, in deep cases he thinks the old method of incision is preferable. Such a fistula is more branched than the superficial, and to excise all the ramifications would be a formidable procedure. In doing an ordinary operation, unless it is very evident that the tract is straight, it is better to cut from above downward, making sure that the exact and entire course of the fistula is laid open, rather than by the quicker method of the older authorities. Incontinence following operation is an important matter. If both sphincters are cut once across at right angles, it is safe, but the exact direction of these fibers must be considered for the anal sphincters are not circular but elliptical. It is therefore sometimes necessary to make an incision from the external opening parallel to the fibers until such a point is reached that a line from it to the internal opening will cross the sphincter fibers at a right angle. When required, there is safety in cutting the external sphincter more than once, provided the internal one does not share in the double injury. The after-treatment is important. If we leave the care of the case to one who will use only superficial applications we may expect a large percentage of failures. At least twice a week the bottom of the wound must be examined in a good light, pockets be broken up and exuberant granulations cut down with iodin, chlorid of zinc, etc. He thinks after the first week these cases do better with fresh air and moderate exercise than if confined to the bed. As regards tuberculosis and fistula he is more hopeful than many. There is the possibility of fistula with phthisis as well as tubercular fistula. Phthisis is a less frequent accompaniment than is often supposed. Less than 10 per cent. of the 139 cases of fistula at the Mount Sinai Hospital in four years had phthisis. In cases of true tubercular fistula he thinks general surgery holds rather than any special rule. If the patient's general condition warrants operation he would not hesitate to operate any more than he would with hemorrhoids, and he considers local anesthesia best. Any fistula that can be excised without too formidable a procedure had best be so treated. If incision seems best it is wise to do it with a cautery instead of with a knife, and thus destroy the organisms and avoid infection.

66. **Head Injuries.**—Rae insists that the presence or absence of infection determines the outcome in these cases. The soft parts can be readily examined. In injury to the bones of the cranium, change of contour can be determined, but the possibility of fracture of either or both tables without change of contour must be borne in mind. Closed injuries may have to be converted into open ones to determine the exact condition, and the escape of cerebral tissue and cerebrospinal fluid means fracture of the base. Hemorrhage from the ear or nose should be interpreted with care, although the probability of fracture is great. The symptoms of injury to the brain are the diffuse lesions of concussion and compression; the former marked by a brief period of unconsciousness, the latter by a recurrent or continuous period of insensibility. The appearance of localized loss of function or symptoms of irritation means a local lesion and points to the seat of it according to our ideas of localization. If depressed bone causing pressure be the cause of the loss of function, the function will be restored on elevating the bone. If this does not restore it, the fact of contusion to the brain is emphasized. Considerable damage to the brain tissue, however, can exist without any local symptoms.

67. **Hemorrhoids.**—Terry has used injections in some of his cases with success. He advises the following prescription for the injections, quoting from an unnamed medical journal: "Rub together 1 dram of salicylic acid and 1.5 drams of glycerin, add 2 drams of carbolic acid. To this add 1 dram of borax and 1.5 drams of glycerin. Let stand until clear, and inject 3 to 5 drops into small piles and 5 to 8 into large ones." This injection should be repeated every ten days, and he has used it exclusively in appropriate cases. He remarks on the harshness of treatment of hemorrhoids sometimes by the introduction of the speculum, etc., and the advantages that quacks gain by their easier methods. Four cases are reported. He does not know that there is any special advantage in the prescription he has employed, though it has been satisfactory to him. He has never used more than 2 minims at any one point, but often injects several points at one visit. He has never seen any sloughing, and only rarely any painful inflammation. He thinks the injection method has a certain utility for patients who will not submit to the knife. The chief danger lies in attempts to make the injections compete with operative surgery in range of application and in promptness of results.

69 A Plea for the Microscopic Examination of the Blood in the Continued and Remittent Fevers Common to Our Southern States. Louis M. Warfield.
70 *Some Remarks on Diagnosis and Treatment of Venereal Ulcers. W. B. Emery.
71 *Report of 150 Cases Receiving the Pasteur Treatment at the Georgia Pasteur Institute. James N. Brawner.

70. **Venereal Ulcers.**—Emery describes the method of diagnosis of chancre, chancroid, abrasions, etc., and his methods of treatment. Simple ulcers require only protection and cleanliness. In herpes and ulcerated balanitis he insists on circumcision, thus removing the cause in most cases. For chancroids he employs carbolic and nitric acid. Swab the surface of the ulcer with pure carbolic acid for the anesthetic effect; then apply nitric acid with a cotton swab. A 40 per cent. formalin solution has been suggested, but he has never tried it. After thoroughly applying the nitric acid he uses a moist dressing of absorbent cotton saturated with bichlorid, 1 to 10,000. This serves to protect the ulcer and absorbs the secretion. Powders are mechanical irritants. He only uses them when the ulcer is very large, irritable and painful. Then he uses the formula of orthoform one part and bismuth subnitrate three parts; this secures almost perfect local anesthesia for twenty-four hours. He has discarded all ointments, except mercurial, and this only in certain cases to stimulate resolution and check phagedena. In many of these cases potassium iodid or

proto-iodid of mercury are useful. For chancre he would use nothing but a 1 to 5,000 bichlorid bath and a moist protective dressing. As regards the diagnosis of chancre he favors waiting until secondary symptoms appear, giving a placebo if necessary and postponing specific treatment until the diagnosis is certain.

71. **The Pasteur Treatment.**—Of the 150 cases treated there has been only one failure, that of an old man, who was bitten severely in the eye, through the nose. Another patient, a small negro boy, developed the disease on the tenth day after commencing treatment and died five days after the symptoms first developed, before immunity could have been established, and the case can not be regarded as a failure. Two patients came after the symptoms had fully developed, and, of course, succumbed. During the last year Brawner treated 36 cases from Georgia; none of them developed hydrophobia. During the same period about 20 were bitten who did not take the treatment, and 4 deaths have already occurred among them. Out of 250 southern cases of mad-dog bite of which he has the record, 170 were treated by the Pasteur method with only one death—that above reported. Of the remaining 80, 16 have succumbed to rabies, or about 20 per cent.

8 A Case of Double Gangrene of Legs Following a Mild Attack of Enteric Fever. A. Dodds.

1. **Pernicious Anemia.**—Houston reports a case of malignant disease in which the blood findings and symptoms were characteristic of pernicious anemia, but a partial autopsy revealed a general malignant disease of the viscera and involvement of the bone marrow. The special points in the case which deserve attention were the condition of the blood and of the bone marrow. The red cells were greatly diminished in number and ran as low as one million per cubic centimeter, showing a marked poikilocytosis, and many of them were of large size (megalocytes). The blood was megaloblastic in type. The red cells showed signs of degeneration. The color index was always high, increasing during observation, and the number of leucocytes was about, or slightly under, the normal. He has been able to find the account of but one similar case. His experience in other cases affords no justification of the attempt that has been made to show that it is impossible to differentiate between the anemias of the pernicious type and grave secondary anemias. He tabulates a large number of cases in which hemoglobin was below 50 per cent. In nearly all it was possible to differentiate between the secondary anemias and the pernicious anemias by the lower color index and generally by the absence of megaloblasts, the one case which he details standing out as an exception. The contention of Stockman, therefore, that pernicious anemia is always the result of repeated small hemorrhages is not supported. Houston notices other conditions which have been described by some as liable to be confused with pernicious anemia, such as changes in the blood in ankylostomiasis, pregnancy, cancer, etc., and points out the differences that exist. The case reported, he thinks, has an

important bearing on the question as to the pathology of progressive pernicious anemia, for by inference we are forced to conclude that the changes found in the bone marrow in cases of progressive pernicious anemia are generally the result of disease directly accounting for the condition of the blood and not secondarily the result of the anemia itself.

2. **Leishman and Donovan's Bodies.**—Leishman and Donovan recently reported finding small oval bodies in the spleen in cases of low fever, chronic dysentery and cachexia, and in July Donovan also found similar ones in chronic malaria. Ross has investigated these forms, studying the type specimens of Donovan, and finds that it is hardly possible to doubt that these are parasites of some kind, probably protozoan, and that we have to do with some novel organism in these findings, and it promises to be a common and important one. The fever charts of Donovan's cases recall the chronic pyrexia with enlarged spleen frequently observed in India, and are not a little suggestive of kala-azar.

4. **Bubonic Plague in Central East Africa.**—The disease known among the natives as kaumpuli which from time to time has decimated the population of Uganda, East Africa, is defined by Christy as bubonic plague, and seems to have been known to the natives for ages, but for the first account of the disease we are indebted to Koch, who, with Zupitza, a German physician, proved it to be genuine bubonic plague. Christy has investigated the matter further, talking with missionaries and others who have observed it, and confirms Koch's original opinion.

15 A Case of Lupus of the Forehead, the Right Arm and the Elbow Treated by Excision. Cecil H. Leaf.
16 A Case of Congenital Heart Lesion. Walter Broadbent.

10. **Occupation Diseases of the Lungs.**—Oliver's lecture reviews these diseases, especially the dust disorders, such as pneumoconiosis (which has been specially observed in French millstone builders and basic slag workers) and ganister-, coal- and gold miners' phthisis. The latter form has been studied in South Africa, and indicates the necessity of hygienic regulations such as have made coal mining in Great Britain a comparatively healthful industry. Metallic trades, such as file cutting and potters' asthma, which seems to be a serious disorder, are also discussed, as well as the dangers from inhalation of gases. In conclusion, Oliver notices the pathology of pneumoconiosis which often leads to fibrosis from which later destructive conditions and secondary infections may arise. It is not always easy to see whether the mischief is due to the direct action of the dust itself or to superadded infection.

11. **Tuberculous Glands.**—The operation for tuberculous glands of the neck is described by Sutcliffe, who insists on the importance of avoiding the internal jugular vein and the spinal accessory nerve. He holds that if operation is decided on, the glands should always be removed with their surrounding cellular tissue, and that instead of tying the internal jugular as a routine measure it should be avoided. The drooping of the shoulders caused by division of the spinal accessory nerve is a serious deformity and causes considerable loss of power, and in children is the cause of almost certain lateral curvature. He has seen many old cases where the sternomastoid and trapezius have atrophied, which served as an object lesson to him not only to treat the nerve with the greatest respect, but to put the incision in the least visible region.

17 Note on "Mansonia" Anopheloides. G. M. Giles.
18 *A Rare Cerebral Complication in Malaria. P. A. Nightingale.
19 Municipal Sewerage. (Continued.) Fred Smith.

18. **Malaria Embolism.**—Though malarial embolisms are not uncommon during the paroxysm of fever, they usually prove fatal, as Nightingale says, from their lodging in some capillaries of the more important cerebral nerve centers. In the case he reports, however, there was simply paralysis of the velum, with some paresis of the vocal cords, followed by slow recovery, as the result of this accident. The patient was an army officer, 32 years of age, who was on the way home from Sierra Leone, the embolism occurring after some days at sea. He thinks, considering the favorable conditions surrounding the patient, that the occurrence indicated a special susceptibility on his part to cerebral embolism; therefore, the question of the safety of a return to a malarial climate for at least some time ought to be seriously considered.

22 *De la dégenerescence maligne du moignon cervical après l'hysterectomie subtotale pour fibrome. L. G. Richelot.
23 *De l'ulcère externe de l'estomac. G. Hayem.

20. **Potable Water for Garrisons.**—The committee emphasize the necessity for the protection of the sources of the water supply. When this can be done efficiently it is unnecessary to resort to sterilization of the drinking water, except possibly temporarily in case of accident.

21. **Gastrotomy for 25 Foreign Bodies in Stomach.**—Eight teaspoons were included among the foreign bodies taken from the stomach of a would-be suicide. Recovery was rapid. Monod, in describing the case, stated that it was the seventy-eighth on record of gastrotomy for a foreign body. In 17 the latter had been multiple. The tolerance of the stomach has always been extraordinary. In 2 cases the foreign body had perforated into the peritoneal cavity without inducing inflammation. The interval before operation was from a few hours to six months in more than half of the cases, and from one to sixteen years in the remainder, with only 2 deaths in this series, a total mortality of 9. Hair balls were found in 9 of the cases. In the case described in detail radioscopy had been negative, and although some of the foreign bodies had been in the stomach for nearly six months, there were no gastric symptoms. The existence of multiple intestinal symptoms and crepitation in the left hypochondrium led to the erroneous diagnosis that the assumed foreign body had passed into the intestines and the operation was commenced at this point.

22. **Malignant Degeneration of Stump of Cervix.**—Richelot has observed 3 instances in which the stump of the cervix left after subtotal hysterectomy had become affected with malignant disease. He knows of 3 other cases, and has found 10 more in the literature. The hysterectomy had been undertaken on account of fibroma in the majority of cases. Hyperplasia of the uterine glands shows a tendency to epithelial malignant proliferation, and this hyperplasia of the glands is an invariable accompaniment of uterine fibromata. He therefore urges total instead of subtotal hysterectomy, whenever possible, and proclaims that fibromatous degeneration should no longer be regarded as a benign process. He admits that a fibroma is a benign tumor, but it is the manifestation of a nutritional disturbance affecting the parenchyma of the uterus and likewise its mucosa, the latter preparing the soil for malignant degeneration later. Besides this, there is always the possibility of phlebitis and complications on the part of the viscera. The general hypertrophy which accompanies fibromatosis is liable to degenerate into epithelioma, either of the fundus or of the stump left after a partial operation.

23. **External Ulcer of the Stomach.**—Hayem describes a lesion on the outer surface of the stomach which he thinks has hitherto escaped attention. It resembles a round ulcer, only that it faces outward and leaves the mucosa of the stomach intact. It may be called an external ulcer, gastric mal perforans or a mixed internal aneurism. In its course it passes through three phases, first resembling a vaccine pustule, then a kind of sac, and finally, a cupola projecting around a defect in-

volving all the layers of the stomach wall down to the mucosa. He has observed it in 8 cases, and always coexisting with chronic ulcers on the inner surface of the organ. This coincidence seems to demonstrate that it is due to the same causal pathologic process, and that abnormal gastric juice can not be the principal factor in the evolution of an ulcer in the stomach wall. The facts observed incriminate nervous influences as more probably responsible for the lesions than any cause inside the organ.

30. Suprarenals in Inherited Syphilis.—Guleke has noticed in 3 out of 8 cadavers of newly born syphilitic infants that the suprarenals exhibited peculiar wedge-shaped or oval foci of necrosis. He found nothing of the kind in 15 non-syphilitic infant cadavers. He relates the particulars of one case. The infant of a prostitute had succumbed two days after birth, and the necropsy showed gummatous hepatitis, interstitial splenitis and intense osteochondritis. In the cortical substance of the suprarenals miliary gummata were numerous, accompanied by interstitial fibrous induration and the necrotic foci mentioned above.

43 Historical Sketch of the Lying-in Rooms in Previous Centuries. R. Müllerheim.—Zur Kulturgeschichte der Wochenstuben vergangener Jahrhunderte.

36. Indications for Forceps Operation.—Fehling thinks that injury of the soft parts would not occur if students were trained in forceps operations and repair of injuries by careful suture under the eye of the professor. He adds that no "practicant" is allowed to leave his clinic without having sutured a perineum once or several times. He thinks that there is nothing to prove that the application of forceps leads to hemorrhage from atony. Hemorrhage from lacerations can be easily controlled. Slight lacerations of the cervix occur in nearly every normal birth, and Emmet's operation is usually superfluous. He states that in 815 forceps operations he has held the forceps himself in only 10, and thinks that by thus entrusting them to the assistants he has done more for the education of his pupils than if he had denounced and banished forceps from his practice. He regards feeble contractions as an indication for their use and advocates resorting to them when all the conditions are favorable and the delivery stage lasts more than three hours.

38. Abnormal Site of the After-birth.—Bayer calls attention anew to the fact that the cervix does not behave the same in all pregnancies. In some it develops by unfolding irregularly, and the physiologic stricture becomes spastic in labor accompanied by spasmodic contractions. The after-birth in placenta previa is inserted in the lower pole of the uterus but not in a correctly regular segment, and hence it develops abnormally. A woman who has had considerable hemorrhage during the pregnancy but who arrives at term without much loss of strength stands a better chance of recovery with a living child, from the placenta previa, than one whose labor commences at term without any hemorrhage during the pregnancy. The same conditions prevail when the placenta is located in the tubal angle. The uterus forms a "tubal segment," as the walls of the tube expand under the placenta. In case of placenta previa it becomes more or less detached and hemorrhages occur, simulating the phenomena of premature detachment of a normally located placenta. The various conditions are shown in cuts. With a placenta located in the tubal angle the uterus becomes saddle-shaped. No special treatment is required for it, except that the possibility of a pathologic process must be borne in mind.

39. Healing of Tuberculous Peritonitis.—Freund describes several cases to show the phases of the healing process in case of tuberculous serous or ulcerative, suppurative peritonitis or peritonitis with adhesions. Each of these three varieties is amenable to operative treatment. This relieves the abdomen of the presence of the effusion, with or without its specific disease germs, and the intervention is followed by proliferation of connective tissue which destroys or encapsulates the morbid products. Mild cases may be treated conservatively, but severe ones require surgical aid. Freund describes 15 cases which emphasize the remarkable benefits derived. In some the cure has persisted for years. Concomitant tuberculous lesions in pleura or lungs healed with the healing peritoneum. Experiences of many surgeons to date show that 65 per cent. have been cured by operative intervention, and 25 per cent. permanently for years to date.

40. Bacteriology of Genital Canal in Pregnancy and Parturition.—Stolz does not regard the presence of bacteria in the uterus as necessarily entailing infection. He thinks that this follows only when the germs are extremely virulent and very numerous.

41. Tuberculosis of Female Genitalia and Peritoneum.—Pape advocates excision of tuberculous lesions in the portio and cervix, but not in isolated tuberculosis in the endometrium until after the ordinary measures have been tried and failed, such as abrasio, injection of iodin and general treatment. In recent cases of general genital tuberculosis radical operations are indicated, but in the chronic cases only symptomatic treatment.

45. **Alopecia from the Use of Thallium.**—Buschke's further experiments have established that the alopecia has nothing to do with the decrease in the secretion of sweat which thallium induces. Also that the alopecia is due to a specific medicinal action on the part of the drug, and that this action can not be diverted elsewhere by producing a superficial lesion at another point.

46. **Soxhlet's Sugar Food in Infant Therapeutics.**—Brüning states that his experience with this substance, added to the milk, has been extremely favorable in the case of 37 infants, some of them very sick. Even those with severe gastro-intestinal trouble gained in weight as well as the others on this diet.

47. **Symptomatology of Tumors of Hypophysis.**—At the necropsy of a woman 39 years old a sarcoma of the thyroid gland was found and also one in the hypophysis. The symptoms were great thirst, fever and polyuria, with spasmodic sneezing. Rosenhaupt gives further particulars of the case and reviews the symptomatology of such tumors in detail. The fever paralleling the polyuria suggested a central process, as also a suspicion of choked disc. Death followed in six weeks after the first symptoms.

49. **Influence of Heat and Light Rays on Cutaneous Temperature.** The action of blue, yellow and green incandescent electric light was studied in this research. Under the influence of the light the part gradually becomes warmer. This direct action of the rays is most marked with the short-wave rays. After two to four hours the radiated side is colder than the other, which fact Sommer explains as due to a reactive rise in the temperature on the other side.

50. **Albumin for Subcutaneous Feeding.**—Trolldenier reports experiments on dogs and 2 clinical cases, in which nutrient injections of a 10 per cent. solution of albumin were applied. None of the albumin appeared in the urine, and he consequently assumes that it was assimilated in the organism. The amount that can be thus given is very small, and the points of the injections were liable to suppurate or at least show a painful tumefaction. He used a manufactured product, midway between genuine albumin and albumose.

51. **Orthostatic Albuminuria.**—Jacobson accepts this form of albuminuria as an indication of degeneracy. He applies the term only to those cases in which the albuminuria ceases after a day's rest in bed, and there is no albumin in the night urine. The proportion of albumin is not dependent on the specific gravity. He considers the albuminuria of puberty as its prototype, both a token of exceptional susceptibility to fatigue.

54. **Cardioptosis and Its Connection with Hepatoptosis.**—Einhorn's communication is based on examination of 926 persons. He found in 22 pronounced cardioptosis, all but 4 being men. In about half of these cases there was concomitant hepatoptosis, probably owing to the downward displacement of the diaphragm. Treatment should be addressed to the general nervous system, with avoidance of positions bending the trunk forward, and of high pillows at night. Drugs are of little if any use, but a mechanical support might be tried, a pad in the corset, for instance.

55 **Gastrosuccorrhea.**—Albu regards the presence of gastric juice in the fasting stomach as pathologic in every instance. He distinguishes between chronic and intermittent gastrosuccorrhea, ascribing the latter to incipient tabes in most cases. It usually begins suddenly, with violent pains and vomiting of gastric juice, and the affection then subsides, sometimes for months at a time. Chronic gastrosuccorrhea is usually found in neurasthenic subjects and in cases of atony, ectasia or ulcer, and is always preceded by some motor disturbance. Corresponding to these fundamental affections the secretion may be hyperacid or not, and the dilution of the juice may mask its acidity. The secretion of urine and of gastric juice are usually in inverse relation to each other.

57. **Complication of Angina with Acute Thyroiditis.**—Kublinski's 4 patients were women, and the sudden onset of the thyroiditis convinced him that the angina was due to rheumatism. Instead of localizing in the joints the affection settled in the thyroid gland. The course was febrile, but there was no suppuration and recovery was complete in 2 to 8 weeks. The pulse was accelerated in each case. He found applications of ice the most effectual treatment. In one case recurrence of the angina six months later was accompanied by recurrence of the thyroiditis.

58. **Paralysis of the Accessorius in Tabes.**—Seiffer has encountered 3 cases of this paralysis among 400 tabetic subjects, and has found 6 recorded in the literature. He describes and illustrates his cases, adding that the tabic neuritis is generally a peripheral or root affection, probably at the point where the root fibers of the vagus and accessorius mingle, as the symptoms of paralysis of the latter are accompanied by others indicating involvement of the vagus.

60. **Diagnostic Import of Displacement of the Liver, Etc., by Meteorism.**—Oppenheim states that when the liver is pushed up by meteorism below it turns on its frontal axis upward and backward and the dulness vanishes. The disappearance of dulness may therefore indicate the first phase of pronounced meteorism not otherwise revealed. It may prove an early sign of progressive peritonitis originating from appendicitis, long before the pulse shows anything wrong. Opium may induce meteorism in the large intestine. The above displacement of the liver does not occur when the entire mass of the intestines is distended, and may thus differentiate the part of the intestine affected. Artificially produced experimental distension of the intestines, even of the rectum alone, is liable to arrest the heart-beat by mechanical action. This effect is still more marked in man on account of the unyielding nature of the walls of the thorax. Relief may be obtained from a fistula opening into the small intestine better than from one in the less elastic large intestine. The displacement of the liver also pushes up the lung.

61. **Exophthalmus and Pressure on Brain.**—In 5 cases personally observed by Flatau, and in 10 reported in the litera-

ture, the cerebral affection accompanied by edema of the lids or decided exophthalmus proved to be a tumor in most cases, in others an abscess, hydrocephalus or chronic serous meningitis. He recommends measuring the eyeballs with the exophthalmometer before and after lumbar puncture. These disturbances are probably due to interference with the circulation in the basal sinuses, especially the cavernosus. The effect is not only mechanical congestion and eventual transudation into the orbital cellular tissue, but the innervation of the orbit also suffers from compression of the sympathetic ganglion. This in turn causes an excessive flow of blood into the retrobulbar tissue. In acute suppurative or inflammatory conditions and in case of a tumor the process is liable to invade the orbit and induce the exophthalmus by direct propagation.

65. **Sputum as Culture Medium for Tubercle Bacilli.**—Hesse has found that scraps of human sputa placed on agar form an elective culture medium for any tubercle bacilli contained therein. The essential requisite for their development is that the alkalinity of the medium must be identical with that of the sputum. This varies with each case. The bacilli in the sputum are almost invariably alive and able to multiply and colonies rapidly develop. He thinks that the facts observed indicate that when the bronchial secretions happen to be of the same degree of alkalinity as the sputa, the lodgment of scraps of sputa in sheltered nooks in the lungs offers unusually favorable conditions for the proliferation of the bacilli *in situ*, which otherwise does not occur. The different degrees of alkalinity of the mucus in man and animals may be the reason why the lesions produced by infection from the other species have so little pathologic importance. He inoculates tiny scraps of fresh sputum on a mixture of 10 gm. agar, 10-25 gm. glycerin and 1,000 gm. distilled water, boiled one-half to one hour and filtered twice, and then poured into tubes in quantities of 25 c.c. in each. One-tenth normal alkaline solution is then added to each tube in varying amounts, ranging from .2, .5 to 1, 2 and 5 c.c. The mixture is then poured out on six plates, and when it has solidified and can be turned upside down the agar is inoculated with a scrap of sputum. The bacilli develop sufficiently for differentiation in one to three days; after one or two weeks the colonies can be differentiated by the naked eye. When this test results positively inoculation of animals is superfluous.

66. **Diagnosis of Marrow Metastases of Malignant Tumors by Blood Findings.**—Kurpjuweit's clinical observation of 6 cases and analysis of 13 that have been published by various writers, have demonstrated that it is possible to diagnose malignant metastasis in the bone marrow even before the discovery of the primary tumor. The diagnosis is based on the finding of large numbers of myelocytes in the blood, accompanying signs of anemia. These changes in the blood are not the result of the cancer cachexia, but are due to the pathologic condition of the bone marrow which becomes transformed into lymphoid marrow in response to the increased demands on it.

68. **Paroxysmal Tachycardia.**—Hoffmann gives the particulars of a later series of 5 cases, 3 of which were under observation for a long time. During the abruptly-commencing and abruptly-ending attacks of tachycardia the heart contractions rose to 140, 200 or even 300 in a minute, and the heart action was somewhat irregular during the intervals. The polyuria observed with the onset of the attack and persisting through it unmistakably indicates nervous influences on the entire heart emanating from the medulla. None of the cases presented any evidence of organic disease. One of his patients had the first attack at 58, and has been in continuously robust health during the fifteen years since. The attacks commenced at the age of 9 in another case. The patient is now a man of 52, and has risen to eminence in his profession. In another, the attacks have always been slight, and of late years the subject has been able to abort them every time by holding his breath or lying down and breathing deep. In a number of cases it has been possible to abort the attacks of "heart galloping," as he calls them, by applying pressure to the vagus. One patient is able to ward off an impending attack by squatting down (Niederhocken). The chief measures for prophylaxis are avoidance of injuries, refraining from smoking and drinking, and overexertion, mental or physical, leading a tranquil life in general.

69.—This was noticed editorially. See page 1348, issue of November 28.

71. **Muscae Volitantes.**—One of Buch's eyes is normal and the other myopic, 4 D. He has been studying this optic phenomenon of muscæ volitantes on himself, as his astigmatism caused exceptionally favorable conditions for such investigation. He found that the floating particles were most numerous after the eyes had been resting at night, and for this and other reasons which he enumerates he concludes that they are formed anew each day, and probably have some intimate connection with the functional activity of the vitreous body. It is possible that they serve as centers of growth. They are seen more distinctly the more myopic the eye, but are essentially a physiologic phenomenon.

73. **Sensitive Test for Bile Pigment in Urine.**—Jolles has found that by the technic described it is possible to detect even very small proportions of biliary pigment in urine, and the reaction is not affected by the presence of hemoglobin or indican. About 10 c.c. of urine are placed in a test tube and 2 or 3 c.c. of chloroform are added with 1 c.c. of a 10 per cent. solution of barium chlorid. After thorough shaking the mixture is centrifuged and the supernatant fluid above the chloroform is decanted. The tube is then refilled with distilled water and centrifuged again. In deep colored urine it may be necessary to repeat this application of the water. After decanting the fluid above the chloroform and sediment the latter is treated with 5 c.c. alcohol, shaken up well, and then two or three drops of an iodin solution is added and the mixture is filtered into a conical glass. The presence of even the slightest trace of biliary pigment will cause the fluid to assume the characteristic green color, as it stands, and the change in color may be hastened by warming. The solution of iodin for the test is made by dissolving separately in 125 c.c. of alcohol each .63 gm. of iodin and .75 gm. of mercuric chlorid, then mixing the two and adding 250 c.c. of concentrated hydrochloric acid. Jolles recommends this test as exceedingly simple and delicate.

75. **Alkaptonuria.**—Alkapton is the product of some anomaly in the intermediate metabolism, according to the conclusions of Langstein and Meyer. In isolating homogentisinic acid from urine containing alkapton a between body is obtained, the lakton of this acid, which responds to the Millon test.

78. **Functional Diagnostics of the Kidneys.**—Koeppe's researches and reasoning apparently establish that the osmotic energy influences the concentration of the urine, but is not directly responsible for the excretion of urine, which depends on the hydrostatic pressure. The latter is also responsible to a certain extent for the degree of concentration, as it determines the amount of the urine, that is, of the water in the urine. The molecular concentration of the urine, and thus its osmotic pressure, are dependent on three factors: 1. On the blood pressure, which determines the amount of water in the urine; 2, on the walls of the glomeruli which are theoretically assumed to be permeable on one side only, and when intact allow the excretion of extremely diluted urine. That

is to say, they control the function of producing a very diluted urine, and 3, on the kidney function involved in the production of a concentrated urine. This latter function we at present locate in the epithelium of the kidney and its vacuoles. A single determination of the freezing-point of the urine is not able to enlighten us in regard to the workings of all three of these factors. Repeated investigation is necessary to determine this, and only when certain values remain approximately the same during the most diverse conditions are we justified in drawing practical conclusions from the findings. If the lowering of the freezing point of the urine is never less than that of the freezing point of the blood, even under conditions such as copious ingestion of fluids inducing the production of a diluted urine, then we may safely assume some disturbance in the apparatus in the kidney, which has charge of the production of diluted urine. On the other hand, we may assume some disturbance in the apparatus which has charge of the concentration of the urine when the variation in the freezing point of the urine is never greater, or only very little greater, than that of the blood. This apparatus, as mentioned above, we assume to be the epithelium of the kidney. Two determinations of the freezing point are sufficient for the diagnosis from segregated urine when the difference between the freezing point of the urine from the two kidneys shows that one is functioning less perfectly than the other. The diseased kidney is always the one which excretes a urine in which the variation in the freezing point most closely approximates that of the blood. When the variation in the freezing point of the urine from both kidneys is greater than that of the blood, then the kidney with urine exhibiting the least variation is the abnormal organ. On the other hand, when the variation in the freezing point of the urine from both kidneys is less than that of the blood, then the kidney excreting the urine with the greatest variation of the freezing point is the diseased kidney. This latter condition has not been pointed out before, but it will be encountered during unusually intense diuresis. To insure an accurate diagnosis the urine should be segregated and investigated both during artificially induced diuresis and during conditions in which a somewhat scanty but concentrated urine is usually excreted. This will afford insight into the capacity of the morbid kidney to excrete diluted as well as concentrated urine. In functional tests of both kidneys at once we have likewise to distinguish between the faculties of excreting a diluted or a concentrated urine. After ingestion of 1.8 liters Salvator water the freezing point of healthy urine ranged from .09 to .26 C., while the amount of urine during the three hours after the test ranged from 1,020 to 2,170 c.c. In compensated heart defects these figures were, respectively, .16 to .17 and 1,187 to 1,822. In genuine contracted kidney .12 to .38 and 609 to 1,543 c.c. In chronic parenchymatous nephritis .35 to .53 and 339 to 1112 c.c. In uncompensated heart defects .59 to .77 and 373 to 413 c.c. In subacute parenchymatous nephritis .83 to .87 and 180 to 217 c.c. Uncompensated heart defects and subacute parenchymatous nephritis thus induce somewhat the same changes in kidney functioning, but in the former it is due to the weak heart action, while in the latter it is the result of some defect in the walls of the glomeruli which prevents their delivering diluted urine. [These researches by Kövesi were described in THE JOURNAL, xxxviii, page 1335, title 36, 1902.] Koeppe thinks that perfection of this method—the "dilution test"—will be an important aid in differential diagnosis. He does not know to date of any means by which to test the functioning of the kidney in respect to its capacity of inducing concentration of the urine. We must bear in mind also that the concentration of the urine will differ after long abstention from fluids, and also after ingestion of salt foods and drinks. The concentration of the urine is due to the presence of organic, as well as of anorganic molecules, and the freezing point indicates the values for each. The electric conductibility of the urine is a convenient and valuable method of estimating the anorganic molecules ,and should supplement cryoscopy.

79. **Diabetes in Relation to Tuberculosis and Arteriosclerosis.**—In Croner's 100 cases of diabetes, tuberculosis was noted in 47, either in the patient or his immediate family, and in 32 free from tuberculosis there were evidences of arteriosclerosis. He comments on the frequency of the coincidence of tuberculosis and diabetes in the same family or subject, and suggests that the development of diabetes in a person with a tuberculous inheritance may be regarded as a sign that the individual has escaped the danger of tuberculosis. The constantly progressive increase of diabetes may possibly have some connection with the decrease of tuberculosis. The well-to-do show the larger proportion of cases of diabetes and lesser of tuberculosis, while in the poorer classes there is more tuberculosis and less diabetes. In regard to alcoholism, he remarks that his experience has been that when associated with severe physical labor, as in the case of men driving beer wagons, stonecutters, etc., diabetes is very rarely entailed, while alcoholism in persons under nervous or mental strain is particularly liable to develop diabetes. In cases of associated diabetes and arteriosclerosis, the former may be due to some nutritional disturbance or irritation of the part of the brain involved in the sugar economy of the body. This view is sustained by the tendency to apoplexy frequently noticed in such cases. There may be absolutely nothing to indicate the participation of the pancreas in the morbid process, while everything suggests a cerebral origin. His detailed analysis of his cases can not be condensed into an abstract.

80. **Relations of Syphilis to Renal Surgery.**—Margulies adds a third to Israel's two cases in which syphilis simulated a surgical kidney affection. Israel removed the kidney in each of his cases, but Margulies recognized the syphilitic character of the lesions after exposing the kidney, and refrained from operating. The complete recovery of the patient after vigorous specific treatment confirmed the diagnosis. The palpation findings and the general appearance of the patient, a woman of 26, suggested a malignant tumor in the left kidney, but functional tests showed that it was working nearly normally, with no hematuria.

82. **Cystoscopic Findings in the Bladder in Case of Uterine Cancer.**—The findings in a number of cases described corroborate the assertions of other writers to the effect that papillary proliferations, nodules, flat elevations and ulcers in the bladder do not contraindicate total extirpation of the uterus for cancer. True carcinomatous infiltration and metastases are very rare and occur mostly at a very late stage.

91 *Necrosis of Skull from Pressure of Bandage. Springer (Prague).—Schädel-Nekrose durch Verbanddruck.

85. **Perforating Ulcer in Stomach and Duodenum.**—Brunner has collected from the literature nearly 600 cases of acute perforation in which an operation was performed, and reviews the various details summarizing them in groups. Only 10 per cent. of the cases progressed to the perforation without symptoms suggesting the presence of an ulcer beforehand. Statistics show that 95 per cent. of the unoperated patients die and more than 50 per cent. within the first twenty-four hours. The gastric ulcers are located on the anterior wall in the proportion of 7 to 1 on the posterior, and nearer the cardia in the proportion of 5 to 3 near the pylorus. They are more frequent in the lesser curvature than in the greater. 122 to 16. The pain after perforation is generally correctly localized. Most of the perforations occurred during November. the fewest in July and August. His records show 265 perforations operated on in England and only 31 in Germany. 58 in America, 17 in Sweden, and 41 in France. In America. Switzerland and France the number of duodenal ulcers nearly

equals that of the gastric ulcers, but in general it is only one-fourth. The ulcer should be excised, and as promptly as possible. Only in the absolute impossibility of excision is it permissible to freshen the edges and suture the perforation. Brunner advises flushing the abdominal cavity with 40 per cent. salt solution when it is very much soiled. In recent cases the abdominal cavity can be entirely closed after thorough cleansing. The best results were obtained when the operation was performed during the first eight hours. The general results have been that one-third of the patients operated on have recovered. In a personal experience with 3 cases, one an ulcer of the stomach, with operation in four and one-half hours after the perforation, and an ulcer of the duodenum, with operation in six and one-half hours, both patients recovered. Another gastric ulcer was not operated on until the eighth hour and the patient succumbed. In 6 other cases in Switzerland in which intervention was not possible until the eighteenth hour none of the patients recovered. The monograph fills 133 pages.

86. **Traumatic Tetanus.**—Less than half of the 24 cases reported were seen before the second week after the accident. Ten of the patients recovered. The incubation was less than a week in a third of the cases. The treatment pursued at Berne is iodin, carbolic acid and the thermocautery for the wound, applied with great energy and as early as possible, immediate injection of serum, in particularly urgent cases directly into the brain or dura, narcotics in abundance and an injection every hour of 1 c.c. of a 3 per cent. solution of carbolic acid, supplemented by subcutaneous saline infusion, nutrient enemata and isolation of the patient in a quiet room.

87. **Myositis Infectiosa.**—Ito has observed 10 cases in Japan in which a benign cutaneous suppurative affection was followed by acute inflammation of the striated muscles. In every case except one, the inflammation progressed to abscess formation, requiring incision. The staphylococcus was isolated in each case. He regards the affection as hematogenic, similar to osteomyelitis, a "pure-culture pyemia."

88. **Origin and Mode of Propagation of Male Urogenital Tuberculosis.**—The experimental research described and the writers' clinical experience apparently establish that tuberculous infection always spreads in the direction of the outflowing secretions, never against the current. The prostate may become infected from the testicles, but the ureters and kidneys never from the bladder. This view is confirmed by the efficacy of extirpation of the testicles in case of tuberculous lesions in them, and also by the arrangement of the lesions in the kidneys and ureters, which always indicates a descending affection. The testicles and the kidneys are liable to infection through the blood or lymph or from congenital infection. The kidney process may spread to involve the ureter and bladder and the prostate, but not to the other kidney nor to the testicle. Tuberculous infection of the testicles from coitus is impossible according to Kraemer's views, as it would have to occur against the current of the secretions. He also excludes the possibility of direct propagation from one testicle to the other. When the second testicle becomes affected it is by the same mode of infection as the first, through the blood or lymph. Tuberculous lesions in the bladder, seminal vesicles and prostate almost invariably proceed from the kidneys or testicles, and this may occur even in the absence of lesions in these organs, or else they may be of independent origin, congenital or hematogenic.

91. **Necrosis of Skull Under Bandage.**—Subsequent to the removal of an angioma on a babe 13 months old, a band of dry gangrene developed on the skull, corresponding to the dressings, involving the skin and periosteum. The gangrenous tissues sloughed off and with them eight flat sheets of bone, some as long as 6 cm. Recovery was not complete until after thirteen months. The band of gangrene almost completely encircled the head, extending from side to side of the brow, and nearly its entire width. The patient presented an enteritis at the time the gangrene developed. The bandage was a "miter," stiffened with starch, and the decubitus developed in three days.

92. **Unusual Causes of Abortion.**—Kleinwächter found that laceration of the cervix was the cause of the habitual abortion in 2 out of his 11 cases. After the tears had been sutured there was no further disturbance from this cause. In 3 or 4 other cases the habitual abortion was due to relics of preceding inflammations in the pelvic peritoneum. In case of an exudate near the uterus conception seldom occurs and rarely proceeds to its normal termination. In 12 cases he noted habitual abortion as due to fibromata of the uterus, heart affections, diabetes mellitus, hydramnion and emphysema of the lungs, the latter once, the others in 2 to 4 cases each.

93. **Treatment of Gynatresia.**—Two cases with complete absence of any cervix were treated by Halban as follows: The first patient was a young woman presenting a hematometra. He made an opening into the fundus and placed the uterus in extreme anteversion, suturing the opening into the fundus in the roof of the vagina. He calls this intervention elytrohysterostomy. The patient menstruated thereafter regularly. The second patient was relieved of a hematoma in left round ligament and ovary, and a hematometra in a rudimentary accessory cornu. The more usual methods of treatment of gynatresia are reviewed.

95. **Etiology of Tubal Pregnancy.**—Anomalies were found in the tube in every one of 10 cases examined, and the nidation in the tube is explained by the irregularities or processes mechanically arresting the ovum.

98. **The Blood During Pregnancy.**—Zangemeister's research confirms the assertions of Nasse that the blood is hydremic during pregnancy. The plasm and the serum must be examined separately. The specific gravity, albuminoid content and molecular concentration are less than normal in the serum during pregnancy, while the proportion of chlorids is higher than at other times. The plasm seems to contain more water than under other conditions. The actual condition is that of a hydroplasmia instead of hydremia, although for certain reasons the latter name is preferable. He found the alkalinity of the blood rather diminished, the red corpuscles somewhat more concentrated than usual, as well as more numerous.

102. **Contagiousness of Leprosy.**—Ryeshetillo thinks that the frequent finding of the lepra bacillus in the throat and nose of subjects with the maculo-anesthetic, the nervous form of leprosy, indicates that there can be no doubt as to the contagiousness of this form. Dehio has recently announced the contrary, but the frequent occurrence of this form in some members of a family while others exhibit the tubercular form is certainly significant.

105. **Fluid for Preservation of Anatomic Specimens.**—Heidenreich discusses the various preserving fluids in use, commenting on the fine appearance of the specimens exhibited at the last Paris exhibition which had been treated by the Riche-Godard technic. They had been soaked twenty-four to forty-eight hours in a fluid consisting of 150 parts formalin, by weight, 1,000 parts distilled water, 10 parts potassium nitrate and 30 parts potassium acetate. They were then drained and transferred to 80 per cent. alcohol for twelve, and then to 95 per cent. alcohol for two hours, after which they were placed in a mixture of 100 parts each of glycerin and distilled water and 30 parts potassium acetate. Equally fine results are obtained with the Melnikoff-Razvedenkoff technic, which includes a bleaching fluid, a mixture of 10 parts formalin, 100 parts water, .5 parts potassium chlorate and 3 parts potassium acetate. The specimens are then transferred to weak alcohol, gradually increasing the strength to 95 per cent. After a few days the color is restored by a bath fluid consisting of 30 parts potassium acetate, glycerin 60 parts and 100 parts water. Heidenreich has found a less expensive and simpler technic to be fully as effective. His method is based on the use of a cheap commercial embalming fluid, holzin, which is a combination of 3 parts formalin and 2 parts methyl alcohol. He used a mixture of 7 per cent. of this holzin in 2 parts of glycerin to 1 of water, to which was added 10 to 20 per cent. of chloral hydrate. A human hand, for example, treated by this technic retained its tints and aspect perfectly for several months exposed to the air in the warm laboratory, without a trace of decomposition. He therefore recommends this technic for general adoption on account of its simplicity and inexpensiveness.

107. **Tuning Fork in Diagnosis.**—Ivanoff proclaims that it is possible to utilize the tuning fork for percussion, and that the findings are more delicate and accurate than by the ordinary methods of percussion in vogue. He describes the theoretical grounds for this assertion, and also gives his experience. He first tried various stringed instruments, etc., but found nothing so well adapted for the purpose as the tuning fork, the handle placed on a flat or curved plate resting on the part to be examined. One of the vibrating prongs is then touched with the percussion hammer, and the vibrations imparted to the palm of the hand holding the hammer appeal to the muscle sense in a characteristic way, besides the information derived by the ear from the musical tone. This mode of percussion will be found useful in outlining certain organs, especially in cases in which ordinary percussion is contraindicated by hemorrhage or extreme sensitiveness to contact, and for children. The ear perceives the strength of the musical note, its pitch, the difference between the pitch as the tuning fork is moved, and the harmony or discord between the tones. The palm learns to perceive the strength of the vibrations, and also the pitch of the tone, and recognizes something analogous to harmony and discord in the regularity of the vibrations. Interfering overtones may be suppressed by damping the prongs at certain nodes, as he shows in 4 cuts.

108. **Copper Citrate in Ophthalmology.**—Krotoff has found a pencil of copper citrate a valuable means of treating certain eye affections, especially pannus. Only 4 out of 39 cases of pannus tenuis were not improved, and only 5 out of 17 with pannus crassus. Chronic conjunctivitis was not affected except in 1 out of 10 cases, and trachoma in only 3 out of 12. He has applied it in 109 ophthalmic cases.

109. **Ligation of Ulnar Artery.**—Susloff warns that an accessory muscle sometimes occurs abnormally in the forearm, and might interfere with ligation of the ulnar artery.

111. **Concentrated Diphtheria Antitoxin.**—Korshun's experiences demonstrated that small, frequently repeated injections of the diphtheria toxin were better tolerated by the horses and resulted in the production of a more concentrated serum than when larger amounts were used. Horses between the ages of 4 and 9 were the best subjects. By reducing the doses and repeating the injections every day they finally succeeded in producing an antitoxin that represented 1,000 units to the cubic centimeter. The local and general reaction bear no relation to the elaboration of the antitoxin, and, in fact, the latter proceeds better when the former are minimal.

113. **Phototherapy in Gynecology.**—Two instruments are described and illustrated devised for the purpose of applying the benefits of electric light treatment directly to the internal genitalia. The first is an incandescent lamp fitted in an ordinary glass speculum, designed for a current of 10 volts. The second apparatus is more complicated, and will bear a current of 50 volts. A continuous flow of water circulates around the lamp to prevent burning the parts. He reports 3 cases rapidly cured by the use of these instruments.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE MEDICAL NEWS VISITING LIST FOR 1904. Weekly (Dated for 30 Patients); Monthly (Undated, for 120 Patients per Month); Perpetual (Undated, for 30 Patients Weekly per Year); 60 Patients (Undated, for 60 Patients Weekly per Year). The Weekly, Monthly and 30-Patient Perpetual Contain 32 pages of Data and 160 Pages of Classified Blanks. The 60-Patient Perpetual Consists of 256 Pages of Blanks Alone. Bound in Flexible Leather, with Flap and Pocket, Pencil and Rubber and Calendar for Two Years. Price, $1.25. Thumb-letter Index, 25 cents extra. Philadelphia and New York: Lea Brothers & Co. 1903.

CLINICAL TREATISES ON THE PATHOLOGY AND THERAPY OF DISORDERS OF METABOLISM AND NUTRITION. By Prof. Dr. Carl von Noorden, Physician in Chief to the City Hospital, Frankfurt a. M. Authorized American Edition Translated under the Direction of Boardman Reed, M.D., Professor of Diseases of the Gastro-Intestinal Tract, Hygiene and Climatology, Department of Medicine, Temple College. Part IV. The Acid Autointoxications. By Prof. Dr. Carl von Noorden and Dr. Mohr. Cloth. Pp. 80. Price, 50 cents. New York: E. B. Treat & Co. 1903.

NORMAL HISTOLOGY. A Manual for Students and Physicians. By John R. Wathen, A.M., M.D., Professor of Surgery, etc., formerly Professor of Histology and Pathology, Kentucky School of Medicine, Louisville, Ky. 12mo. Pp. 220; 114 Illustrations. Cloth. Price, $1.00 net. Philadelphia and New York: Lea Brothers & Co. 1903.

INFECTION AND IMMUNITY, with Special Reference to the Prevention of Infectious Diseases. By George M. Sternberg, M.D., LL.D., Surgeon-General U. S. Army (retired), Ex-president of the American Medical Association. Cloth. Pp. 293. Price, $2.00. New York and London: G. P. Putnam's Sons. 1903.

INFECTIOUS DISEASES. Their Etiology, Diagnosis and Treatment. By G. H. Roger, Professor Extraordinary in the Faculty of Medicine of Paris, etc., Translated by M. S. Gabriel, M.D., New York. With 43 Illustrations. Pp. 864. Cloth. Price, $5.75 net. Philadelphia and New York: Lea Brothers & Co. 1903.

ANNUAL REPORT OF THE HEALTH DEPARTMENT OF THE CITY OF LOUISVILLE, KY., for the Fiscal Year Ending Aug. 31, 1903. M. K. Allen, M.D., Health Officer, Louisville. Paper. Pp. 77. Louisville: The Bradley & Gilbert Co. 1903.

CLINICAL TALKS ON MINOR SURGERY. By James G. Mumford, M.D., Assistant Visiting Surgeon to the Massachusetts General Hospital. Cloth. Pp. 115. Price, 75 cents. Boston: The Old Corner Bookstore.

THE WORTH OF WORDS. By Dr. Raicy Husted Bell. With an Introduction by Dr. William Colby Cooper. Third Edition, Revised and Enlarged. Cloth. Pp. 307. Price, $1.25. New York: Hinds & Noble.

THE ANTISEPTIC AND GERMICIDAL PROPERTIES OF GLYCERIN. Hygienic Laboratory—Bulletin No. 16. By M. J. Rosenau. Paper. Pp. 30. Washington: Government Printing Office. 1903.

REPORT OF THE COMMISSIONER OF EDUCATION FOR THE YEAR 1902. Volume I. Cloth. Pp. 1176. Washington: Government Printing Office. 1903.

Address.

THE TREND OF GYNECOLOGIC WORK TO-DAY.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON OBSTETRICS AND DISEASES OF WOMEN, AT THE FIFTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT NEW ORLEANS, MAY 5-8, 1903.

A. PALMER DUDLEY, M.D.

Professor of Gynecology, New York Post-Graduate Medical School. New York; Professor of Gynecology, Dartmouth Medical College, Hanover, N. H.; Surgeon to Harlem Hospital.

NEW YORK.

An honor unsolicited extended to a member of this body should certainly be most highly appreciated, and I wish to express my most sincere gratitude to you for the honor of being chosen to preside at this meeting, an honor which I never for a moment even dreamed would fall to my lot. And if, as I proceed in the discharge of my duties, you are made painfully aware of my incompetency to occupy such a position; if you murmur regrets for your act of last year in electing me to this honorable position, I shall feel that it is but just.

I will be candid in saying that when in the small hours of the morning, nearly a year ago, I received a telegram announcing my election, accompanied by congratulations, my pleasure was marred by a feeling of regret, for I had promised to attend the meeting at Madrid, and I knew that it would be impossible, unless I deserted my post and confrères here. But, having the interest of our national body at heart, and unsolicited being one of its officers for the present year, I forwarded an apology to the committee at Madrid for my absence, and put my longings for the ocean aside. Why? Because I instantly realized that a visit to this ancient and delightful city of the south would be attended with equal pleasure and profit; and I am sure that ere this meeting adjourns my prophecy will be fulfilled.

Therefore, anticipating pleasure for you all for the next few days, I know that you will indulge me, if I inflict on you for a short space of time the necessity of listening to a review of what is already ancient literature in gynecology and obstetrics.

If I at the close of my remarks look wise and offer you advice for the future, be it ever so erratic, which is the customary duty and privilege of your chairman, you will realize that I am only following in the footsteps of my predecessors. But, instead of trying to interest you with ancient literature and paint glowing pictures for you for the future, I prefer to tell you of what I have accomplished in the past year in my effort to place before you at this meeting a just and unbiased expression of the best men in the country (whose lives have been devoted to our chosen specialties) concerning the trend of gynecologic work to-day, which, I am sure you will agree with me when I am finished, shows a marked tendency toward conservatism rather than radicalism in operative work.

A quarter of a century ago, he who would have advocated conservative surgery on the uterine appendages of woman would have been considered by the profession at large, the world over, a fit subject for an asylum.

How the lapse of time, study and experience has changed every feature of this picture of the past, until at the present time he who would cling to the traditions of that period would be looked on as antiquated even in his youth. The necessary courage required by the operator of a quarter of a century ago to withstand public opinion against his invasion of the abdominal cavity of woman, would be looked on at the present time, even by laymen, as an evidence of cowardice or ignorance on the part of even the family physician, if he hesitated for a moment to advise that his patient, be it child or aged person, should receive the necessary and expected relief attendant on prompt invasion of the abdominal cavity for pathologic changes from whatever cause, and to the average physician or surgeon so easily demonstrable at the present time.

What a panorama a review of the past quarter of a century presents to those who are familiar with these changes. The names of the star actors in this domestic drama—in which tragedy has played no little part—are already recorded in history as masters of their art and profession. But, even though nothing shall be taken from them, to their students, their national professional heirs, must be given the credit of at least making the effort of rescuing womankind from the ravages of an enthusiastic aspirant for surgical honors, who could only see radical removal of all in his path as his license to success. What a parody! How many thousands of suffering, misguided women have offered up their pelvic organs as a sacrifice, for the simple promise from such an ambitious aspirant for professional preference, that such sacrifice would immune them from all future unpleasant conditions peculiar to their sex. And how bitterly have these poor misguided women regretted in the years that followed their misplaced confidence so generously bestowed, when the knowledge was forced on them by sad experience that they had changed one condition of suffering for another equally as disagreeable.

But such is life in all things experimental, and our profession has never been an exception to the rule. These sacrifices, so far offered up by woman to her suffering kind, are bearing fruit for good, as I shall hope to demonstrate with the consensus of opinion expressed by the leading operators of the United States. You, gentlemen, are as familiar with the history of the evolution of gynecology and abdominal surgery during the past quarter of a century as I am. It is, therefore, un-

necessary for me to do more than call your attention to the names of those who have been pioneers in this process of transition from sacrifice to conservatism.

During this period electricity played a prominent rôle in an effort to conserve the pelvic organs, and was championed by Apostoli of France, and Cutter of New York; but this method of treatment was of short duration, and passed rapidly into oblivion, while conservatism of whatever nature was for a time lost sight of, in the smoke of battle, fought out between members of our profession as to whether it should be complete hysterectomy or suprapubic; whether it should be abdominal or vaginal, or the combined method. These men were so anxious to work and had struggled so energetically with every phase of the argument that they forgot apparently that woman in the future might return and demand something more. It was not until the nerve specialists called attention to the fact that we were sowing the wind and reaping the whirlwind for these poor women, that many of us realized what we were doing—prematurely endowing them with hot flashes, the rapid taking on of fat, the loss of their generative function and regrets for their unsexing.

To Robert Battey of Georgia and his followers in this country; to Lawson Tait and his followers in England, and to the many German and French operators, whom it has been our pleasure to know and respect, should the credit be given.

It was my privilege to see Sir Spencer Wells do his twelve hundredth abdominal section in the Women's Hospital of New York in 1881 or 1882. The technic of that operation was the forerunner of the coming of Lister. With the advent of the latter, the Mephistopheles of surgery vanished from view. Fear no longer haunted the mind of operator or patient, and the peritoneum, the bugbear of former years, seemed to readily acquiesce in the evolution. With this confidence in the restorative powers of human nature came the reckless disregard of the consequences in the future. And she who dared to complain of symptoms referable to her pelvis, be they minor or major, which rendered her more or less an invalid, was at once condemned to the operating table, and the sentence—ablation of her pelvic organs—immediately carried into execution. Ere by delay in many cases (from my standpoint of view, be it honestly stated) the patient might recover from her fright and change her mind before the dawn of another day.

During this time, covering a period of about twelve years, woman, the unprotected, has been the victim of professional opinion, and God knows she has paid the penalty. But when they had returned in an unlimited number to the shrine at which they had formerly worshipped with every conceivable form of discontent and domestic unhappiness as the only fulfilled promise of absolution from their former disabilities, given to them under a solemn promise, the eyes of the profession (who claim the honor of practicing our specialty) opened wide with astonishment, coupled with regret (in the heart of every honest man) who saw by after-experience that his promise had reacted to his own discomfiture. The dire consequences of this wholesale ablation of the generative organs of woman and the apparently sympathetic tolerance evidenced by the peritoneum led the writer of this paper, in 1887, to begin a series of experimental operations on the uterine appendages, which, strictly speaking, was more radical than a hysterectomy, because it trusted such surgical work on the appendages to the efforts of nature for a cure, while the ultimate results were more conservative to the woman, because by the skill of the surgeon and the aid of nature she had been restored to health, and could still consider herself a woman.

I do not claim to be the first to have performed conservative surgery on the ovaries of woman. I desire to give full credit in this report to every man, and his work, from whom it has been my privilege to glean. From their writings, and knowledge in reference to this matter, and in so far as I have been able to discover, I give to Carl Schroder the honor of being the first to practice and publish conservative surgery on the uterine appendages, who, in 1885, published the report of five cases, the after-results of which are not known to us in America.

It was in 1887 that I published the result of my first case, which was followed by pregnancy in three months, and, from fear of a return of her former trouble, a criminal abortion resulted. In 1889, August Martin of Greifswald published ten cases; in 1891, eleven more, and in 1893, six additional. One of the 27 cases died; 24 cases were observed for a prolonged period. Of these, two had recurrent disease, and eight became pregnant. Among 41 salpingectomies reported by Martin, only one became pregnant; a point which I desire to emphasize thus early in this report, with reference to the much more frequent occurrence of pregnancy, providing the tube is not mutilated.

You will readily understand, and I think the conclusions you may be able to draw from the summing up of this report will be evidence sufficient that I am not finding fault with the past, and the brilliant work that has been accomplished, but rather that I am looking to the future, and hoping that progress will be made in the direction that I have chosen to believe it will be in the next decade.

I am not, of course, as familiar with the work of my confrères in Europe as I am with those I am in touch with in my own country, but those I have come in contact with, during my sojourns in various parts of the old country, prove to me that our confrères abroad get up very early in the morning. Von Winckel, Hofmeier, Schatz, Zweifel and P. Muller approved this method of procedure as early as 1893. In the same year Pozzi published twelve cases. Hegar, Leopold and Fritsch opposed it, but I am sure if they are not already converts to conservatism rather than radicalism, they will give the subject serious thought, for they are wise and fair-minded men.

From 1887 the work of reform, so to speak, began in an active manner, and hysterectomy "from whatever excuse could be plausibly given," received and felt the desire among certain members of the profession to break away from the cold-blooded method of ablation of the woman's pelvic organs, and if possible seek a higher sphere of work in her behalf—that of checking disease, which would ultimately result in her unsexing, and by skill and careful treatment secure the restoration to her (with an ability to perform their functions) her pelvic organs that had been so ruthlessly sacrificed in the past. This seemed to be a world-wide desire, for the work was simultaneously undertaken in this country and abroad. But little attention was paid to it by the profession at large until 1891, when Polk in his masterly address before the American Congress of Physicians and Surgeons, held in Washington, championed the preservation rather than the sacrifice of woman's pelvic organs, if by skill, perseverance and courageous surgery this could be accomplished in the future.

In very many of the cases we meet with it is necessary to do triple operations on the genital tract, such as curettage, trachelorrhaphy and perineorrhaphy before it would be justifiable to attempt conservative work on the appendages, with any prospect of a cure, or even the prevention of a return of the pelvic trouble. Even then the pelvic work must in many cases be accompanied by uterine and ovarian suspension in order that the function of menstruation should not be interfered with, or the possibility of pregnancy removed.

Dr. S. C. Gordon of Portland, Me., reports two cases where complete oöphorectomy was performed and within three years each patient became pregnant and went through full time and delivered a well-developed child. Of course, some very small portion of one or both ovaries was left, and perhaps included in the ligatures. Catgut was used, and to this may be due the result, inasmuch as the tube may have become patent after absorption of the ligature. He has used only catgut for ligatures or sutures since 1884. In another case he removed one ovary, resected the other, did a ventrosuspension, and after a lapse of two years the woman conceived and bore a child at full time. In several other cases puncture of one or both ovaries has been done with relief to the most obstinate and troublesome symptoms.

This method of procedure was not resorted to by the older operators. That was before the days of antisepsis and the mortality rate for even simple ovarian tumors ran high, so much so that we members of the house staff would lay wagers with one another as to how long a patient would live after such an operation.

Mark the difference in my own experience in a lapse of five years from that time (1882). A patient with pelvic disease which indicated operative procedure came to me for relief, but begged that I would not remove her tubes and ovaries. I opened her abdomen, broke up the adhesions in the pelvis, split her ovaries in half, took out portions of them that were diseased, slit up the tubes, washed them out, put them back, and closed the abdominal wound. This patient was relieved of her symptoms and retained her normal functions. Three months later she conceived. However, she was so afraid that pregnancy and labor would undo the good work I had done for her that she had an abortion performed. Then she conceived a second time. Since then I have continued to do conservative work on the tubes and ovaries. My work in this direction has differed somewhat from the work of other men, in that I have not tried to save everything, but I have tried to save what I thought would perform its function normally. In all I have operated on 269 cases in this way, and without a death, until Christmas week of December, 1902, when I promptly lost two from violent general septic peritonitis, introduced into the women's abdominal cavity by the hands of a septic house surgeon who unconsciously infected a number of others in the hospital for other operators at the same time.

In doing conservative surgery on the tubes and ovaries the first thing to do is to endeavor to put the inside of the uterus into a condition to become healthy. If plastic work on the genital canal is necessary, this must be done also. Then open the abdomen and do what work is indicated in each individual case.

In deciding what to do, the age of the patient is an important factor, as is also her social position. The domestic relations of the woman should also be considered. The after-effects of radical work and the dangers to which the patient is to be subjected should also carry weight. These five cardinal points should always be borne in mind. If the patient is a girl, anemic, with cystic ovaries and displaced uterus, whose future is just beginning, you would not like to unsex her if you could save her appendages. Dr. William D. Howard of Baltimore, one of the nestors of gynecologic surgery in our country long years ago, opposed such work, and cites many cases where his opinion was substantiated. He is still to the fore at the age of 82.

Then her social position. If the patient is a hard-working woman whose life is one of toil and who possibly would not be benefited by conservative work, you would not want to subject her to the hardship of a possible necessary secondary operation. If she is a society woman, floating about half the day and half the night, and neurotic because of her dissipations, I should not so regret it if I did unsex her. If the domestic relations of the patient were such that a radical operation would give an excuse to her husband to run around after half a dozen more, I would rather not give him the excuse. Then, again, if the work I should like to do would necessitate a prolonged anesthesia and the woman not able to stand it, I would prefer to do any operation that would not take so much time.

If the patient is over 40 years of age, I would not be so anxious to do conservative work, although Kelly goes so far as to advocate the removal of fibroid tumors from the uterus of a woman who has passed the menopause by a number of years. I deem it advisable to do your plastic work first, unless you have to do a good deal in the pelvis that may make peritoneal drainage necessary, in which case it is better to make two distinct operations, at different sittings.

I do not hesitate to remove small fibroids from the uterus. I have removed as many as sixteen from one woman and left her appendages. I would not hesitate to open up a hydrosalpinx, wash out the tube and drop it back. I would not hesitate to open up a hematosalpinx, providing the tube was patent at the uterine end. If the tube is occluded at the uterine end, and if it was not the result of sepsis from abortion or gonorrhea, I would not hesitate to open it and wash it out. If I found an ovary with a cyst, no matter what size, I would not hesitate to remove it and leave what healthy tissue I could find. There is one condition that may exist within the woman's pelvis, however, that requires the most radical and careful treatment, and that is dermoid cyst of the ovary—the most deadly thing in a woman's pelvis. Therefore, let me entreat you, when you get a case of dermoid cyst, not to let one drop of its contents touch the other pelvic organs.

If it be the question of an heir to inherit a large property, or if husband and wife were very anxious for offspring, I would do any amount of conservative surgery compatible with their wishes and safety.

Professor Polk and myself have discussed this subject thoroughly. We would open the abdomen of any woman to make sure of the cause of sterility, if this be requested, and that is not the least of the conditions for which I would operate. I would go still further and say that if there were certain forms of pyosalpinx which are non-septic, in which the tube has not been destroyed, but is patent, I would wash out the tube and try to save it, provided it was not of recent date. (See cases of pyosalpinx in table of various operations.)

Individual judgment must decide whether or not an ovary or tube can be saved. (See consensus of opinion of operators.) After resecting whatever portion of the ovary is necessary, I close the ovarian wound with fine

silk, the ordinary floss silk No. 00, such as is sold by the dry-goods stores. I never use catgut for this purpose, because I can not be positive that catgut is absolutely aseptic, and I have no wish to introduce sepsis with my suture material. Moreover, catgut that would last twelve days in the tissues, the time necessary for healing, would oblige me to use a very large size and a very large needle, and the result would be troublesome oozing from the needle punctures. Therefore, I use a very fine silk and cambric needle, and carefully approximate the parts. The silk will last as long as you want it to. Two years ago there came into the hospital a woman with a retrodisplaced, bound-down uterus. The tubes were also bound down. At her request I did not remove the appendages, although the condition was not as good as in many other cases. I broke up the adhesions, resected a half of each ovary and tube, and did a ventrosuspension. The woman recovered perfectly. She came occasionally to the clinic, as requested for observation, and one day a very large speculum in the hands of a student caused her much pain. At that time she was a few days passed her period and she at once began to bleed. We operated on her expecting to find an ectopic gestation, but instead I found a blood-vessel in the broad ligament had been ruptured and there was a large hematoma. At the second operation I found that the silk which I had used at the first operation, four and a half months previous, which was a twisted Japanese silk, although fine, was still unabsorbed at the tip of the tube. A year ago the woman again presented herself, seven and a half months pregnant. In this case only one-half of one tube and one-half of one ovary had been saved.

The surgeon who now does radical work in all cases, and I mean by that removal of organs that could possibly be saved to the woman, is open to the criticism of not being a conscientious man. He may be looked on as not even a good mechanic, for skilful men are now doing myomectomy for fibroid tumor in suitable cases with conservatism as their goal, and a large number of pregnancies have followed their work, whereas but a short time ago complete hysterectomy seemed to be their only recourse. Of the 269 patients from whom I have removed portions of tubes and ovaries, coupled with various forms of plastic operations, including ventrosuspension and ovarian suspension, I have so far been able to trace 43 pregnancies, 35 going to full term and 8 abortions. Many of the 269 cases have, of course, been lost sight of, as is inevitable in hospital practice.

Now, take, for instance, a case of salpingitis pure and simple. The fibriated extremity is closed, dilated and club-shaped. The tip should be opened with scissors and the contents evacuated. It should then be washed out. If the tube contains pus it is best to wash it out before probing, in order that we may not carry septic material further into the tube. The tube should be aspirated, then washed out with one of these four solutions: (1) Normal salt solution; (2) 20 per cent. carbolic acid; (3) 1/5,000 bichlorid; or (4) a very weak solution of permanganate of potassium. After this is done, open and probe the tube. Catch up the tube and straighten it out, bearing in mind the direction of the uterine portion. Introduce the probe gently, and if it passes into the uterus, we will know that the tube is patent. Then, if the tube has not already been washed out, this is done. If the uterus has not been packed previously, it will be noted that some of the irrigating solution will be noticed in the vagina. If so, what excuse have we for removing the tube? None. Our aim is to keep that tube open so it will not close again; therefore, you do a phimosis operation on the end of the tube. Split up the dilated portion and roll it out. Then with fine silk and cambric needle, with over-and-over stitch, you go all around the tip of the tube, until you come to the place you started from, the probe being still in position. The fimbriæ have been used up and absorbed and you have got to have something to aid the passage of the ova into the uterus. The canal of the tube is lined with ciliated epithelium. These cilia are constantly waving back and forth and it is this wave-like motion which carries the ovum into the uterus.

In hematosalpinx (dilatation of the tube with blood), the same condition exists, except that instead of being filled with serum or seropus, the tube contains blood that should have been carried off through the uterus at the menstrual period. It is usually due to displacement or twisting of the tube causing a damming up of the blood. This condition is not septic and tubes thus affected can be saved. As the condition is usually due to displacement of the uterus, this must be remedied. The adhesions must be broken up and the uterus replaced and kept in position by ventrosuspension and the tube treated in the same manner as for salpingitis.

Hydrosalpinx, a dropsical condition of the tube, due to repeated congestion and arrested drainage from any cause, is usually the result of displacement of the uterus. It should be treated as a salpingitis and hematosalpinx.

In all these cases it is necessary to have a full history in order to determine the different varieties of tubal disease. A history of gonorrhea, or abortion, or puerperal infection will at once put us on our guard, for in such cases the affection is usually septic. One word in regard to pus: It is well to remember that non-septic pus, formerly called "laudable pus," is free from odor, while septic pus is very foul. If the pus of pyosalpinx is septic, beware of it. In 95 out of 100 cases occlusion of the tube is present after septic abortion. In the other cases the pus will flow into the uterus. The latter cases are favorable. In all pyosalpinx cases the field of operation must be carefully protected with gauze packing in order to prevent peritoneal infection, be the method used abdominal or vaginal. It is well to have at hand a large hypodermic syringe or an aspirator and to tap the pyosalpinx before you open the tube, in order to ascertain the character of the pus. If septic, inject the tube with a 1/1,000 bichlorid solution and withdraw the fluid, repeating this procedure a number of times, in this way avoiding possible infection of the surrounding parts by evacuating the contents before splitting up the end of the tube. If it is difficult to get the tube into view we must place the patient in the Trendelenburg posture so that we can see the tube *in situ*. After we have made sure that the tube is patent, we need not hesitate to drop it back into the peritoneal cavity. If it is not septic, the peritoneum will take care of it. Moderate oozing will also be taken care of by the peritoneum, but we must guard against any distinctly bleeding point at the end of the tube.

Now, respecting complications and after-treatment of these cases. One complication is fibroids, small or large. If possible, myomectomy should be done. In doing this one point is to be remembered; we must not take the fibroid off too close to the uterus, for in that case we will leave a gaping wound. Enucleate the tumor in such a way as to leave sufficient peritoneal covering to be able to close the wound without traction. Split the capsule and take the fibroid out and remove the tumor by morcellement if necessary. Then with catgut No. 1,

chromic—I do not use silk in the fundus, because the uterine tissue will contract and leave the sutures loose—bring the flaps of peritoneum together with a continuous suture. Good drainage is essential in these cases. If the fibroid is buried deep in the uterine tissue, it is well to make an opening into the uterine cavity to provide for drainage. This will guard against a collection of blood or pus within the muscular structure of the womb. Two or more rows of sutures are sometimes necessary to close the uterine wound left by the removal of a fibroid. If there are several fibroids, never mind how small, repeat the procedure, removing all. Cul-de-sac drainage is sometimes necessary.

In order to hold the uterus up in these cases, I do ventrosuspension by means of two salmon-gut sutures inserted through the fundus and abdominal wall, and leave them there three weeks. At the end of that time a firm suspensory ligament will have formed, and that will hold the uterus up. This is essential in conservative surgery on the tubes.

I never do ventrofixation. There is a marked difference between that and ventrosuspension. Fixation is a pernicious procedure. It immobilizes the uterus and interferes with diaphragmatic action of the pelvic structures. Rather than do fixation I would suggest knuckling the round ligaments and in this way shorten them and hold the uterus forward, by the operation of Ferguson, McGannon or Byford. The latter operates somewhat as I do. Bear in mind that the object is to suspend the uterus so that it can not become retroverted and again drag down the tubes and ovaries.

After the patient has been put to bed you may be nervous about the case for the first 24 or 48 hours, but the patient will usually get well. If you close the abdominal wound properly, there is no reason why the patient should have a hernia; neither is there any danger of intestinal paresis if the patient is properly treated. As soon as she comes out of ether she should be given a saline, to increase the vermicular action of the intestines, empty the stomach and carry away gas. Three, four, five or six Sedlitz powders should be given. Do not let the patient lie all the time on her back, but have the nurse move her first on one side and then on the other. This will prevent the formation of adhesions by changing the position of the intestines. The bowels should move at the end of 24 hours. This is important. The intestinal canal is the best drainage-tube you can have. Do *not* give morphin, for morphin will mask every symptom that can possibly arise; it will stop peristalsis; it will stop all secretions; it will permit sepsis; it will produce nausea which can not be distinguished from the continued nausea of ether or from the nausea of intestinal obstruction. No food should be allowed until after the bowels have moved. Then you can begin with milk and Vichy. You will find that this treatment will produce good results.

It is well to keep the patient in bed for fourteen or sixteen days. If you have made ventrosuspension I advise you to allow the stitches to remain in for twenty-one days. They may possibly cut into the abdominal wall and make it sore, or even cause a small stitch abscess, but this will do no harm. The first menstruation may be delayed. As soon as the first symptoms appear it is my practice to put the patient to bed and keep her there until two days after the flow has ceased, for she has not fully recovered from the operation, and the parts are not yet able to bear the distension and engorgement. (A mild cathartic should also be given.) If the ovary enlarges during this temporary stage of congestion, put the icebag on the abdomen, and keep it there day and night until the fever following the congestion has subsided. I give hot, vaginal douches at a temperature of 116 F. four times a day for such a condition. If this is unpleasantly hot to the external genitals, I apply an ointment of aristol or zinc. I do not poultice the abdomen. The icebag is better. Intercourse should be forbidden for two months after the operation.

Since 1887 many operators have taken up this conservative work and excellent results have been recorded. The work has advanced to such an extent as to revolutionize pelvic surgery and save to thousands of women appendages that would formerly have been sacrificed. The operative mortality is significant, sex is maintained, the subjective and objective symptoms are relieved in the vast majority of cases, and over 10 per cent. of the women are known to have continued to bear children. When we bear in mind that the majority of these cases can not be followed up it is reasonable to suppose that the number of parturients is much in excess of 10 per cent.

The following material, which I have secured by correspondence, is appended in alphabetical order:

W. H. BAKER, BOSTON.

One case. Removed one ovary and tube. Resected other ovary. Woman became pregnant.

This case is peculiarly interesting because the patient with one-half of one ovary gave birth to twins.

H. J. BOLDT, NEW YORK.

Total number of cases	82	Which ovary not stated	1
Left ovary diseased	32	Left tube resected	20
Right ovary diseased	33	Right tube resected	19
Which ovary not stated	13	Which tube not stated	1
Left tube diseased	24	Left ovary removed	0
Right tube diseased	23	Right ovary removed	4
Which tube not stated	1	Left tube removed	3
Left ovary resected	26	Right tube removed	4
Right ovary resected	26	Ventrosuspensions	7
Which ovary not stated	12	44 patients, average age	30
Left ovary punctured	4	Pregnancy	1
Right ovary punctured	3	Died	0

Dr. Boldt adds:

My opinion, based on numerous observations, is that whenever possible a part of the pelvic organs should be saved by plastic surgery instead of being removed by radical operation. I have not found that conservative operations done on patients who have suppurative disease of the adnexa have been productive of subsequent pregnancies, but the menstrual function has been retained, which is very essential because of the nervous system.

My invariable rule when operating on ovarian tumors has always been to leave whenever possible a part of the ovarian stroma, not so much in the hope that pregnancy will follow, but in order to maintain the function of menstruation.

I hardly think ignipuncture of the ovaries justifiable or conservative; best left alone.

J. BRETTAUER, NEW YORK.

Total number of cases	31	Right tube resected, etc	7
Left ovary diseased	12	Which tube not stated	10
Right ovary diseased	11	Left ovary removed	3
Ovary diseased not stated	13	Right ovary removed	4
Left tube diseased	11	Which ovary not stated	3
Right tube diseased	13	Left tube removed	3
Tube diseased not stated	12	Right tube removed	6
Left ovary resected or punctured	7	Which tube not stated	2
Right ovary resected or punctured	7	Pregnancies	3
Which ovary not stated	11	Ventrosuspensions	2
Left tube resected, etc	8	Appendectomy	1
		Vaginal section, at least	17

A. BROTHERS, NEW YORK.

Total number of cases	50	Pregnancies	8
Vaginal sections	18	Ventrosuspensions	6
Laparotomies	25		

Dr. Brothers, in reporting the 50 cases, regrets his inability to give fuller details concerning the occurrence of pregnancy, because the majority of his cases were

hospital patients whose after-history could not be traced. So far as known to him, his results were satisfactory.

W. L. BURRAGE, BOSTON.

Total number of cases	187	Anatomic recovery, per cent.	64
Symptomatic recovery, per cent.	73	Died	3
		Pregnancies	23

The summing up of Dr. Burrage's statistics readily evidence the fact that he is one of the most successful operators of whom it is my privilege to quote. I wish I could publish his paper in full, as it is a most convincing argument in favor of the work of which my paper is the subject.

A. P. CLARK, CAMBRIDGE, MASS.

Total number of cases	13	Average age, over	30
Pregnancies	3	One or both ovaries diseased	5
Recovery	12	One or both tubes diseased.	8
Improved	1	Resection of tubes or ovaries, per cent.	100
Married (date for 3 only)	8		

HENRY C. COE, NEW YORK.

He has had five cases of pregnancy following conservative surgery of the ovaries, etc.

E. B. CRAGIN, NEW YORK.

Total number of cases	33	Right tube resected	13
Left ovary diseased	26	Left ovary removed	16
Right ovary diseased	27	Right ovary removed	17
Left tube diseased	32	Left tube removed	17
Right tube diseased	29	Right tube removed	15
Left ovary resected	10	Implantation of ovary	1
Right ovary resected	10	Died	1
Left tube resected	16	Married	33

Dr. Cragin reports that in only one of his cases was second operation required.

He reports only one pregnancy because of inability to trace his cases, they having been hospital cases only.

C. G. CUMSTON, BOSTON.

Total number of cases	47	Bilateral resection of ovary.	31
Married	20	Unilateral resection of ovary	16
Single	27	Pregnancies	12
Age, from 18 to	35	Recovery	25
Ovarian dysmenorrhea, per cent.	100	Improvement, decided	12
		Unknown	10

In all of Dr. Cumston's cases we find that fine catgut was used as suture material in the ovary with good results. He reports among the number one most interesting case where with only half an ovary remaining the patient gave birth to a healthy child two years after operation.

RICHARD DOUGLAS, NASHVILLE, TENN.

Total number of cases	30	Resection of tubes	7
Married	5	Resection of ovaries	23
Salpingitis	7	Pregnancies	5
Cystic ovaries	23	Died	0

In summing up his report Dr. Douglas is of the opinion that many of the small cystic ovaries formerly resected do not need anything but puncture of the cysts. He is also convinced that either gall bladder or appendiceal operations should have accompanied the work. He is not in favor of resecting the tube.

A. PALMER DUDLEY, NEW YORK.

Total number cases	269	Left tube removed	29
Left ovary diseased	204	Right tube removed	26
Right ovary diseased	188	Ventrosuspension	99
Left tube diseased	59	Appendectomies	32
Right tube diseased	53	Pregnancies (to term, 35; abortions, 8)	43
Left ovary resected	130	Implantation of ovary	7
Right ovary resected	141	Vaginal section	11
Left ovary punctured	25	Kidney suspension	1
Right ovary punctured	30	Married or single (data on)	198
Left tube resected	28	Married	154
Right tube resected	22	Single	44
Left ovary removed	41		
Right ovary removed	26		

These operations were performed at the following places: Private sanitarium, New York City, 101; private cases elsewhere, 41; Mary Hitchcock Hospital, Dartmouth College, 14; Mary Fletcher Hospital, University of Vermont, 5; Harlem Hospital, New York City, 32; Post-Graduate Hospital, New York City, 76.

SHERWOOD DUNN, LOS ANGELES, CAL.

Dr. Dunn read a paper before the American Association of Obstetricians and Gynecologists, Aug. 18, 1897, on conservatism in ovarian surgery.[1]

J. G. EARNEST, ATLANTA, GA.

Total number of cases	8	Cured or much improved	7
Resection of ovaries	8	Not improved (ovaries afterward removed)	1
Bilateral oöphorectomy (2d operation)	1	Pregnancy	0

Dr. Earnest favors conservative work, and from his own successes is encouraged to continue.

ALEX. HUGH FERGUSON, CHICAGO.

Total number of cases	69	Pregnancies	12
Left ovary diseased	46	Ventrosuspension (Kelly)	5
Right ovary diseased	23	Anterior transplantation of round ligaments (Ferguson)	17
Left tube diseased	22		
Right tube diseased	17	Appendectomies	30
Left ovary resected	26	Cholelithotomies	13
Right ovary resected	16	Nephrotomies	5
Left ovary removed	20		
Right ovary removed	7		

Dr. Ferguson also describes six additional cases of surgery on the tubes with or without participation of the ovaries. Owing to the complicated character of the intervention these cases are not enumerated with the preceding. No pregnancies followed.

C. C. FREDERICK, BUFFALO, N. Y.

Total number of cases	125	Right ovary removed	25
Right ovary diseased	48	Left ovary removed	47
Left ovary diseased	65	Number of pregnancies (one woman pregnant 3 times since operation)	8
Right tube diseased	60		
Left tube diseased	73	Ventrosuspensions	12
Right ovary resected	23	Appendectomies	8
Left ovary resected	18		

J. RIDDLE GOFFE, NEW YORK.

Total number of cases	115	Laparotomies	4
Vaginal sections	111	Pregnancies	10

Professor Goffe is one of the most earnest advocates of the vaginal route (through the anterior fornix) for this form of work that we have in America. The above statistics evidence that fact. He has many followers, and the question is still debatable with us in America, viz.: Abdominal versus vaginal route.

A. GOLDSPOHN, CHICAGO.

Dr. Goldspohn is justly entitled to rank as one of the pioneers in conservative surgery of the ovary. On June 5, 1901, he read a paper[2] before the American Medical Association in which he reported 97 cases of cystic degeneration of the ovary treated conservatively by incision and ignipuncture. Pregnancy followed in 10 cases. In all laparotomies results were satisfactory two years after intervention. In one-half the vaginal sections, results were unsatisfactory. Results were good after inguinal section.

S. C. GORDON, PORTLAND, ME.

See text of my article, in which two cases are mentioned.

J. D. GRIFFITH, KANSAS CITY, MO.

Cases of resection of ovary.	4	Ventrosuspensions	4
Age, all under	28	Pregnancies	3

WILLIAM H. HUMISTON, CLEVELAND, OHIO.

Total number of cases	5	Right ovary resected or punctured	0
Pregnancies	5	Left ovary removed	1
Left ovary diseased	4	Right ovary removed	5
Right ovary diseased	5	Left tube removed	1
Left tube diseased	1	Right tube removed	5
Right tube diseased	5	Ventrosuspensions	3
Left ovary resected or punctured	3		

According to Dr. Humiston's report, one woman became pregnant after both ovaries and tubes were supposed to have been removed. Evidently some portion of ovarian structure must have been left. See quotation from Dr. Gordon's report.

CO-OPERATIVE WORK IN REGISTRATION METHODS AND VITAL STATISTICS.*

W. A. KING.
Chief Statistician for Vital Statistics, U. S. Census Office.
WASHINGTON, D. C.

The subject of vital statistics, or rather of mortality statistics, which is the only branch discussed in this paper, is perhaps more interesting to members of this Association than to any other class, inasmuch as in certain particulars they are responsible for the returns on which these statistics are based, and because such statistics furnish the means by which progress in medical science is measured.

To accurately serve this and other purposes, however, it is necessary that all statistics of this kind—national, state and local—shall be compiled under a definite system of general application, and that the data shall be collected under a similarly definite system, having direct reference to the exact statistical and other uses for which they are designed.

Many systems of collecting the data have been experimented with, but to all persons of extended practical experience it has become a settled principle that no adequate results can be secured except through compulsory laws requiring the registration of each death and the obtaining of an official burial or removal permit before the body is interred or otherwise disposed of. It may safely be said that unless this is made the fundamental requirement, the registration of deaths will be incomplete, and any statistics based on the recorded data will be defective.

Under our form of government all legal provisions on the subject must be left to the individual and independent action of the several states, or of the cities organized under state laws, and while many of the states and most of the principal cities have laws or ordinances providing for the registration of deaths, they differ widely in their requirements and results. A good many of them have been futile from their inception because the proper fundamental principles have not been observed.

The greatest utility of registration to the general public, and as still more particularly affecting the medical profession, consists in the availability of the data for tabulation and analysis of the agencies affecting health and disease. As stated by Dr. Elisha Harris: "The practical relation of well-kept and complete records of mortality to the correct estimation of sanitary experience and prevention of diseases and premature death is so important that sanitary authorities and the wise and effectual application of public health measures demand that the mortality registration shall be both complete and accurate." The statistical treatment of the data also demands that they shall be uniform, so that the tabulated results may reach their highest value for comparative and analytical purposes. They are not so now.

The great desirability of uniformity in the general provisions of law, of system, and of methods of securing and tabulating results has long been recognized by all persons who have either attempted to make original compilations of the returns from different places, or to extract comparable figures from the various statistics published, and frequent efforts have been made to bring about a more satisfactory condition of things in this respect.

Success in this direction, however, depends on many other things beside a general sentiment in its favor. It requires a vast amount of hard, continuous and persistent work, time and money, that can be effectually supplied only by some body that has a permanent organization and a paramount interest in the general—as distinguished from the local—results, and can become the active agent of the various interests in determining proper lines of action, forms and methods; in publishing and distributing the necessary documents to all parties whose approval and co-operation are necessary, and beyond this in keeping all of the machinery up to the mark after it is put into operation.

Fortunately, this work can now be performed by the United States Census Office, which has been made a permanent bureau of the government and is charged with the preparation of an annual report on vital statistics of all states and cities that maintain a complete and satisfactory system of registration. Considerable progress has already been made in this work, and it is the purpose of this paper to explain what has been done, what is being done, and what is contemplated in this line, and the relation of the various agencies in promoting the extension of the registration system and the improvement of its dependent statistics.

The plan for extension and improvement of registration methods and results developed by the census office, as the central compilation bureau and the active agent in carrying it into effect, in co-operation with the authorized representatives of the principal organizations interested—so far as such bodies have acted in the matter—and the principal registration officials, may be stated as follows:

1. To determine the reasons for failure of so many of the laws providing for registration, and to formulate the principles on which legislation must be based to avoid failure.

2. To construct and recommend for general adoption as a standard form for reporting deaths a certificate or return, of convenient size and arrangement, that shall provide for all of the details required for legal, statistical and other purposes.

3. To outline certain correct methods of practice with respect to the examination, filing and preservation of certificates and of making returns to state officials, for the guidance of local registrars who receive the certificates and issue burial or removal permits.

4. To decide on a satisfactory system of classification of causes of death for statistical purposes and to furnish compiling officials a comprehensive statement of the details of the classification, with a working index by which the deaths reported in thousands of different terms can be uniformly compiled under the proper titles.

5. To furnish all practicing physicians a descriptive statement of the classification adopted, with an explanation of its practical application in statistical work, and a list of terms very frequently used by them in reporting causes of death concerning which more definite information is necessary to permit proper classification.

6. To advise medical colleges of the nature and scope of the movement undertaken, and to suggest a course of instruction for medical students in registration methods and statistics.

7. To make a study of the forms of statistical tables published by local authorities in annual reports, and

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Hygiene and Sanitary Science, and approved for publication by the Executive Committee: Drs. S. Fulton, Seneca Egbert and H. M. Bracken.

monthly or weekly bulletins, with the view of formulating a uniform series of tables considered desirable for this purpose.

8. To determine what forms of tables should be included in the annual reports of the census office in order to furnish the greatest practicable amount of information for general purposes.

9. To enlist the assistance and co-operation of all organizations, societies, or persons interested in the subject of registration or its results, in reaching satisfactory conclusions regarding each projected step in the proceedings, and, finally, in carrying each step into practical effect.

A beginning was made with the publication of Census Circular No. 71, containing a paper prepared by the experienced and capable registration officials and statisticians constituting the committee on demography and statistics in their sanitary relation of the American Public Health Association, which paper outlines the essential requirements of a law for the registration of deaths and prescribes a standard form of death certificate, with an explanation of the use and importance of the items of information called for.

Following this general plan, the international classification of causes of death, then coming into general use in the United States, was adopted by the census office for its annual reports, and work was at once commenced to make the extensive labor involved in classifying the returns received from all registration areas available for the benefit of local statisticians, by preparing a comprehensive index to the classification as applied in practical work.

The subject of uniformity and progressive action was presented to the consideration of the Conference of State and Provincial Boards of Health of North America, at its meeting in 1902, and that body gave its approval to the movement by the appointment of a committee to co-operate in its advancement and by the adoption of the following resolution:

RESOLUTION OF THE BOARDS OF HEALTH CONFERENCE.

Resolved, That a committee be appointed by the Conference of State and Provincial Boards of Health of North America to co-operate with the United States census office and with similar committees from the American Public Health Association, American Medical Association and from other organizations, in the promotion of the uniformity and comparability of mortality and other vital statistics and their satisfactory presentation in statistical reports and bulletins.

The "Manual of the International Classification of Causes of Death" was then printed and distributed by the census office. This explains the titles of the classification—their application is statistical work—compares the classification with that previously used, and gives an alphabetical index showing to which titles nearly 2,000,000 deaths reported at the censuses of 1890 and 1900, in thousands of different terms, were referred. This is fully cross-referenced, and the terms are also rearranged in a tabular list showing exactly what terms are included under each title. Certain general rules for the disposition of cases in which two or more causes of death were jointly reported are included. Further work is in progress for deciding a satisfactory method of disposing of jointly returned causes of death adaptable for general use. This very difficult problem appears to have been solved by Dr. Cressy L. Wilbur, medical referee for the census vital statistics, in his plan of numerical rating, on which he has prepared a special paper to be presented to the consideration of this Association. So far as tested here the plan promises admirable results attainable by a simple and easy method.

The general adoption of the international classification and the use of the "Manual" referred to will insure a comparability in the various mortality statistics published that can not be secured in any other way, and the notes and memoranda expressing the opinions of all persons using the classification on the merits of the classification itself will be filed and arranged for presentation to the commission of revision, which holds its next meeting in 1910. In this way the united opinions of all American users of mortality statistics can be made most effective in securing desirable modifications in the classification. All persons who make use of the international classifications are invited to file any notes, criticisms or suggestions for this purpose that appear pertinent to them.

The work of the census office and of the committee on demography, also the "Manual" and the "Standard Certificate" referred to above, were specially endorsed and approved by the American Public Health Association at its last annual meeting (Dec. 8-12, 1902) in this city, and the committee was authorized to represent that association in further work on the same lines. As a very complimentary recognition of the work of the census office the chief statistician for vital statistics was appointed chairman of the committee for the present year. The following resolution was adopted by the association:

RESOLUTION OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

Resolved, That the efforts of the committee on demography and statistics of this association, in conjunction with the United States census office, to secure the extension of the registration area by the enactment of suitable laws and the use of a standard form of certificate of death, as shown in Census Circular No. 71, be heartily commended and that the committee be further authorized and directed to co-operate with the census office, the United States Public Health and Marine-Hospital Service and other departments of the Federal government interested in vital statistics and with similar committees from other associations in the work of promoting the adoption of suitable registration laws and the extension of the registration area, the proper compilation and presentation of vital statistics by states and cities in weekly or monthly bulletins and annual reports, and also in further work relating to the extension and practical use of the international classification of causes of death, the disposition of jointly returned causes and all preliminary work relating to the next decennial revision.

A resolution was drafted and presented to Congress reciting the condition of registration in the United States; the necessity for registration under uniform laws; describing the movement initiated by the census office in conjunction with the American Public Health Association; expressing approval of the movement, and requesting "the favorable consideration and action of the state authorities, to the end that the United States may attain a complete and uniform system of registration." This resolution passed both houses of Congress, and was approved by the President Feb. 11, 1903. The text of the resolution is given below:

RESOLUTION BY CONGRESS.

Whereas, The registration of births and deaths at the time of their occurrence furnishes official record information of much value to individuals; and

Whereas, The registration of deaths, with information on certain points, is essential to the progress of medical and sanitary science in preventing and restricting disease and in devising and applying remedial agencies; and

Whereas, All of the principal countries of the civilized world recognize the necessity for such registration and enforce the same by general laws; and

Whereas, Registration in the United States is now confined to a few states, as a whole, and the larger cities, under local laws and ordinances which differ widely in their requirements; and

Whereas, It is most important that registration should be conducted under laws that will insure a practical uniformity in the character and amount of information available from the records; and

Whereas, The American Public Health Association and the United States census office are now co-operating in an effort to extend the benefits of registration and to promote its efficiency by indicating the essential requirements of legislative enactments

designed to secure the proper registration of all deaths and births and the collection of accurate vital statistics, to be presented to the attention of the legislative authorities in non-registration states, with the suggestion that such legislation be adopted; now, therefore,

Resolved, By the Senate and House of Representatives of the United States of America in congress assembled, that the Senate and House of Representatives of the United States hereby expresses approval of this movement and requests the favorable consideration and action of the state authorities, to the end that the United States may attain a complete and uniform system of registration.

(Approved Feb. 11, 1903.)

Following this action, a circular (No. 100) was prepared containing the resolutions adopted by Congress and the American Public Health Association, the paper of the committee on "The Essential Requirements of a Law for the Registration of Deaths and the Collection of Vital Statistics," and a specimen form of an adequate law, drafted in accordance with the principles laid down by the committee. This circular has been sent to the governors of all states that do not now have an effective system of registration. It has also been sent to all medical societies, medical journals, registration officials, and other persons known to be interested in the subject.

The form of law presented in this circular is an improvement in many respects over any of those now in operation. The ideas governing its construction may be stated as follows:

1. The creation of a state registration service, fully authorized to carry out the purpose of the law.

2. The prohibition of burial or removal of dead bodies without a properly authorized permit, based on a complete and satisfactory certificate of death.

3. The use of a uniform certificate for obtaining the information desired as a precedent to issuing the permit.

4. The fixing of the responsibility for making the certificate and filing it with the local registrar, and the obligation to make the return complete in all of its details.

5. The fixing of responsibility on the local registrar for a critical examination of the return and for seeing that all of the information required is properly stated before accepting it.

6. The fixing of responsibility on the state registrar, or chief administrative officer under the law, for examination of all returns made by local registrars, and for immediate action in case of delinquencies, or to obtain data, corrections, etc.

These provisions are based on the theory that the purpose and intent of any such law is to secure a complete and properly executed return of every death that occurs —that the form of certificate adopted indicates what constitutes a complete and proper return—and that no return is complete and proper that does not supply the data desired for all purposes of registration as fully and circumstantially as is possible, by searching inquiry, under the conditions of the case.

Replies so far received from governors show that many of them are favorably disposed toward recommending such legislation at the next session of their legislatures, indicating a probable extension of the registration area that is most gratifying. To insure such action the medical societies, journals and physicians in each state should unite to exert their powerful influence. State and county medical societies, in particular, should adopt some concerted plan of action by which the cooperation of the legislative authorities can be secured. Probably all of the members of this Association are also members of state or local societies, and, therefore, each one can contribute materially to the success of this movement by his personal efforts.

The most perfect laws, however, do not execute themselves, and to reach, interest and instruct those persons whose duty it is to administer the laws or to make reports under them, other circulars have been prepared, as follows:

No. 101, on "Practical Registration Methods," designed for the guidance of local registrars, describes the "Standard Certificate" and explains the necessity and use of the various details required concerning each death; outlines a simple system of filing and preserving the records and of making returns to state officials; gives the titles of the international classification and explains the relation of causes of death as reported to classification for statistical purposes. It also gives a long list of indefinite or unsatisfactory terms frequently used by physicians in reporting deaths, that should not be accepted in such shape, with explanatory notes showing what further information should be required in such cases. This circular will be sent to all registration officials.

No. 102, on "Relation of Physicians to Mortality Statistics," is issued for the use and benefit of physicians who have to make out certificates of death in compliance with registration laws, by acquainting them with the scope and requirements of the international classification, which has been adopted by all of the registration states and by most of the principal registration cities for the compilation of their mortality statistics. Such statistics, to be comparable, must be uniform; and to be valuable for scientific purposes they must be accurate. Their chief value is in the distribution of deaths by causes, but the cause of death must be properly stated before it can be properly classified. In this particular the entire value of the statistics depends solely on the lucidity and certainty with which the physicians supply the information.

In all statistics of deaths by causes there is much too large a proportion of unknown or indefinite items for which the physicians alone are directly responsible and which they alone can remedy.

It is probable that the defect in this particular is largely due to the fact that there has heretofore been no general and comprehensive plan to direct the attention of all physicians to the use of their certificates for statistical purposes, and to exhibit the necessities and requirements in this respect by explaining the classification used, and by specifying wherein certain returns are incomplete, indefinite, or unsatisfactory. This circular is designed to furnish such information. It will be sent to every physician in the country, and it is confidently expected that they will appreciate the importance of the matter—the purpose for which the circular is issued—and will manifest their appreciation by making their certificates conform to the suggestions noted, as far as possible.

It should be considered that the classification, in itself, is but a selection and arrangement of titles only, under which deaths reported in thousands of different ways must be compiled, and that the assignment of any death to the proper title requires a definite statement of the course of disease or the sequence of causes resulting in the death.

Following the detailed list and explanation of the titles is a list of indefinite and unsatisfactory terms very frequently used by physicians, with similar explanatory notes. The terms in this list can not be properly classified as given, and should never be used without further explanation.

It is not to be expected that an entirely definite and accurate statement of the cause of death can be made in

every case. There will undoubtedly be cases in which the exact cause can not be ascertained and others in which an accurate diagnosis is impossible, but an observance of the suggestions made in this circular will very largely reduce the number of cases that must necessarily be classed as unknown or ill defined.

What has been said above relates wholly to the statement of the cause of death, which is always furnished by the physician. But while this is the most important item, a complete return of any death requires a statement of other personal and statistical particulars concerning the death, and the blank certificate or return used for reporting deaths should be regarded as simply a specification, in convenient form, of the legal requirements in the case, all of which are intended to be observed.

The relation to and influence on the mortality from different diseases, of age, sex, color, conjugal condition, nativity, parent nativity and occupation, are of the utmost importance, and the preparation of uniform statistics for all registration states and cities requires that these items, and others necessary for record, shall be given just as fully and as accurately as the cause of death.

The making out of a certificate of death should not be considered a perfunctory matter. A complete and accurate certificate is required of physicians as a legal obligation, under the law—as a moral obligation to their clients for the protection of the rights and interests of those dependent on them—and as a professional obligation, to further the advancement of medical science. In the last respect it should be regarded as one of the highest duties of physicians, as scientific, professional observers, to record their experience in individual cases in accordance with some definite and general system so that the whole result of such professional observations may be properly classified, tabulated, analyzed and made to contribute in the greatest possible degree to the sum of knowledge essential to material progress in medical and sanitary science and public hygiene. In this respect registration is only an intermediary process—a means of adapting a mass of observed facts to systematic treatment and their reduction to numerical standards for analysis and comparison. There can be no doubt that if physicians will take this view of the subject, and act accordingly, they can make the statistics derived from their returns much more accurate and valuable.

Circular No. 103, on "Medical Education in Vital Statistics," gives a synopsis of the circulars previously described; explains the movement for the extension and improvement of registration data and statistics on uniform lines, and suggests to medical colleges and schools the desirability of initiating a course of instruction for students on registration methods and vital statistics. This circular has been sent to all medical colleges and schools.

All of the circulars and the "Manual," referred to above, relate to different phases of the same general plan. By means of them it is sought to convey to all persons interested a comprehensive knowledge of the details of the plan and of their relation to the same, in accordance with the ideas and opinions of the experienced registration officials and statisticians who have joined in the movement. The census office has cheerfully assumed the labor and expense of preparing, printing and distributing these documents and of the correspondence incidental thereto, so as to enable all those interested to get together and to co-operate effectively in the movement for uniformity and accuracy.

The sole object of these circulars is to promote uniformity in laws, forms and methods, for mutual advantage, and to do so in accordance with the opinions expressed by authorized experts. The form of law given in Circular 100 is designed, primarily, to apply to states which do not now have effective laws on the subject, and the other circulars have been framed to assist in carrying out laws constructed on the lines indicated. Some of the provisions of law specified and of the suggestions made as to forms and methods might be adopted to advantage in all of the states and cities now classed as "registration," and it is hoped that whenever changes in existing laws, methods or forms become necessary or convenient they will all see the advantage of uniformity, and will adopt measures in harmony with those described.

The circulars on "Practical Registration Methods" and "Relation of Physicians to Mortality Statistics" are in many respects applicable, whatever the provisions of existing laws, forms of certificates, or methods of practice may be, but they will not be sent to any local registrars or physicians in registration states or cities until such action is approved by the local registration officials. So far as heard from, such officials have given their hearty approval and consent, and have expressed the opinion that the circulars will prove of great value in securing more complete and accurate returns.

The preceding statements describe the movement for the extension and improvement of the registration system and for increasing the value of the recorded data, principally with reference to their use for statistical purposes—representing the ultimate stage of mortality registration as here considered.

In the practical work of compiling and presenting such statistics there is also room for improvement in order to make them more complete, more accurate, and more thoroughly comparable. This is recognized and provided for in the general plan, as stated in the first part of this paper.

This subject was discussed at the last meeting of the Conference of State and Provincial Boards of Health of North America, and was covered in the resolution then adopted (q. v.), and will be taken up by the committees of the various associations which join in the movement for uniformity.

The general adoption of the "International Classification of Causes of Death" and the use of the "Manual" insures a much greater degree of accuracy and comparability in the statistics of deaths by causes, but there are other important factors the relation of which to the cause of death and to each other should be shown in a more uniform manner than at present. The action of the committee will, therefore, be directed toward formulating a series of uniform tables to be recommended for use in all annual reports and monthly or weekly bulletins published by registration state or city offices. To assist the committee in this direction the census office is now collecting and arranging all forms of statistical tables published in the local reports or bulletins.

It is the desire of the census office that its annual reports relating to mortality statistics in registration areas shall supply the greatest possible amount of information desired by all persons who make any practical use of the data. In order to develop ideas and opinions on this subject a series of tentative tables has been prepared,

showing what forms have been selected as a basis for consideration. These will be sent to all of the principal registration officials who compile statistics, committees of representative bodies, etc., and suggestions will be invited concerning changes or additions necessary to adapt them to the widest uses. Within the limitations imposed by the character of the data available, time and space in publication, the effort will be made to supply what is wanted.

The first annual report is now being compiled. It will, necessarily, form the model which subsequent annual reports will follow until the next census is taken in 1910, in which year also the international classification will be revised. This makes it particularly desirable that the ideas of officials and statisticians as to the contents of these reports be communicated promptly.

One observation which has a bearing on this matter and which also shows how improved methods in the census office have been of advantage to users of these statistics, may be permitted here; the census reports are generally distributed through the members of Congress, in the same way as other public documents, and heretofore senators and representatives have been notified that certain reports had been placed to their credit, leaving the public and persons interested to find out that the reports had been issued and to make application therefor to their member of Congress. Under this system many persons interested in particular reports did not discover that they had been published until it was too late to make use of them, and many other persons received copies of reports in which they had no particular interest.

When the "Twelfth Census Report on Vital Statistics" was published (July, 1902) it was determined to remedy this condition as far as possible, and as soon as the volumes were available for distribution a circular letter was prepared and sent to all registration officials, members of scientific societies and persons known to be interested, notifying them of the fact and advising them how the reports could be secured. This made it certain that all such persons would promptly receive the report —if they wanted it. And the demand has been such that a third edition is now being printed.

In the circular letter referred to, announcing the publication of the report, criticism and suggestions were invited, and this statement was included: "Under the permanent census organization, annual reports will be made for registration areas, and I will be particularly obliged for practical suggestions as to forms of tables, etc., that you think should be included in order to make the statistics of the greatest value to all concerned."

Many complimentary acknowledgments were received, but no "practical suggestions as to forms of tables" for the annual reports have yet come to hand.

As a general thing, statisticians compiling such reports are anxious to give the public what it wants, when it is possible for them to ascertain what is wanted.

If the movement described in this paper meets with the approval of the Association, it is hoped that a committee will be appointed to act in co-operation with the committees of other bodies. Its assistance will be most valuable and most welcome.

DISCUSSION.

DR. SENECA EGBERT, Philadelphia—I think the duties of all men in my profession have been increased since the beginning of this work of which Mr. King so interestingly speaks. We ought to do all we can to further this work of registration and to increase the registration area. The great difficulty is going to be in the rural districts. We have a large number of our cities fairly well registered, in comparison with our rural districts. If I am not mistaken, only 14 per cent. of our rural population have anything like well-kept statistics; and that is mainly in the New England states. As to other cities, a much larger proportion have fairly good registration, although the methods of collecting and recording statistics have not been at all uniform; and, as we see to-day, the labor devolving on the Census Bureau has been materially increased by this irregularity and lack of uniformity in registration. Now, the Census Bureau is sending to every physician in the country information about the international classification, and they are also urging our various registering officers to adopt the necessary forms and data, so that eventually there shall be no difficulty at all in securing accurate returns. In Philadelphia we average from 400 to 450 deaths a week and, with a properly instructed clerical force, we should have no difficulty at all in getting proper returns, according to the forms agreed on, as to practically every death. For years, every month that I was at all dilatory in the matter, I have had a man come to my office to obtain my birth reports for the preceding month. Now, this could be done just as easily with regard to the reports of deaths. If such an employe were to call on physicians with the proper blanks and explain the importance of the matter it would not be very long before we would be getting an almost perfect return of deaths in the city. But this can not be done so readily in the country, and it will be more difficult to obtain the data than in the cities. I do not think the average physician to-day is impressed with the importance of this matter as he should be. In regard to my own instructions to students, I have not properly appreciated it, but hope to do better hereafter. Nor do I think that the sending out of a letter or circular to every physician of which we have been told to-day is going to be sufficient. I think it is going to be a matter for the state municipal and governmental authorities to take up and drill into the profession at large, until we all come to a thorough appreciation of it; and I think few things will help to educate a thinking man as to the importance of this matter so much as the data given in the last Census Reports. It was a revelation to me to see how progressive science has cut down our death rate in the last decade. It gives me more hope in my personal work than I ever had before. I think it would be a good thing if some of the most striking parts of these data could be condensed and sent to every professional man in the country, along with these circulars of information and forms, to impress on him the value of the work being done, and how much greater that value would be if he did his share. The physicians of Philadelphia were recently notified not to use the old-fashioned death certificates, and were requested to make our reports according to the new forms, which call for the same data as the standard certificate of death, though not exactly like it in detail. That was within the last three months, I think. Our municipality has practically adopted the suggestion of Mr. King.

DR. CRESSY L. WILBUR, Lansing, Mich.—Did Philadelphia do anything with reference to international classification?

DR. EGBERT—I understand that the city will soon endeavor to adopt the international classification of causes of death.

DR. C. L. WILBUR—Philadelphia is probably the oldest city in the country to use the alphabetical system, and I was in hopes that it would join with Boston, Washington and other cities in using the international classification. We are using the standard blank in Michigan. It is adopted by law, I think, in Vermont, and it is used in Indiana, New York and Colorado. I like it better than our old form. As to the country districts, I think in Michigan we have reports from the township clerks of every township in the state. Some of them in the upper peninsula do not average five inhabitants to the square mile; nevertheless, they all report either that no deaths have occurred, or give the names of those who died, sending in the detailed certificates. We never have a

district delinquent for more than two consecutive months. If they do not make reports promptly we get after them; and they all take pains—as far as they are able (some of them, of course, not being educated men medically)—to send in the returns in correct form. If any items of special importance are omitted we mark a red cross at the place and then send a duplicate certificate, with a cross at the corresponding place, to the registrar, with a circular letter explaining the uses of the information specially desired, pointing out the items omitted, and asking him to see the undertaker, or whoever had charge of the body, get the data that was omitted, and send it on with the next report. We also call his attention to the fact that he should not accept an imperfect report or certificate, and that if he does not supply the missing items, or give good reasons why they can not be secured, deduction will be made from his compensation as provided by law; that is, 25 cents for each certificate. We also write the physicians when necessary. When one sends in a return of death from, say heart failure, or cancer, without specifying the part of the body, we write him a personal letter telling him why we need the information, and that his return is incomplete. We are also going to take the pamphlet that the Census Bureau distributes, print a short list of the most unsatisfactory returns, mark them with an index finger, and send them to all these physicians; so that they will always have their attention more or less directed to the fact. The registrars will also be instructed to refuse to accept (as they have done in a number of cases) grossly unsatisfactory returns such as "heart failure." Unfortunately, our registrars are changed often. If we could only keep them in office for longer terms we could accomplish better results. This pamphlet I regard as one of the most important actions ever taken for the improvement of registration. We send it out to all our physicians, with a circular commending it to them. We also sent a circular to all our registrars, with a special pamphlet of that sort. I believe that by referring the physicians from time to time to this pamphlet, and with the co-operation of the registrars, we will work out great improvement in the accuracy of our statistics. It seems difficult for some of them to comprehend what ought to be said and what ought not to; and sometimes they leave out the main thing.

DR. EGBERT—Dr. Wilbur has shown the essence of the whole matter. There is a head in his state that follows up every man in the state. Unfortunately, however, our registrars are too apt to be changed about for political reasons. For many years I had considerable intercourse with reference to this matter with our former registrar, who was heartily interested in this subject. He went into it almost as Dr. Wilbur has gone into it here, because it was of much real importance to him; and he was always pleased to enter into the details of the subject and give any one whatever information he could. But he was deposed by a change in the political administration, and the city lost a valuable servant. As for Philadelphia, we have recently had a bill passed providing for a Department of Public Health and Charities, to be in charge of a physician who will appreciate the importance of the work. I would like to ask Dr. Wilbur to give us roughly the cost of maintaining the system in his state.

DR. WILBUR—The compensation is 25 cents per certificate of death, which is paid by the county, and is the only fee connected with the system. We exempt from that payment cities of 10,000 inhabitants and over, where the salary of the clerk is supposed to compensate him for the service. We have no birth certificates, though we have had a bill reported by the committee on state affairs of the legislature that provides for the registration of births. It was reported unanimously by the committee, but I do not know how much further it will go. It provides for a certificate of birth similar to that used in New York. There will be a fee of 15 cents to the registrar and 25 cents to the physician, making a total of 40 cents. This may be thought a little high by the legislature; but if they cut it down too much I fear that we shall not obtain satisfactory results. If we pass this law we may not get all the births, but I think we shall register about 95 per cent. of them.

DR. J. N. HURTY, Indianapolis—In the collection of mortality statistics in Indiana we follow pretty closely the system in use in Michigan; and we pursue the same method of keeping each individual certificate that Dr. Wilbur has described. After three years of this work we have no difficulty now in getting the number of deaths, ages, sexes, etc. The great trouble is to learn the correct cause of death. We have thought a great deal of how this is to be remedied. In many instances the physicians are not well enough educated to know what the cause of death is; and in other instances, despite their education, they do not know. So we thought for a while that it would be better for them to write in the word "unknown" when they did not know. We subsequently changed that opinion, however, when we began to get in numbers of certificates showing that nobody knew what the cause of death was, making the confusion worse than it was before. We have had many examples of that character. A state senator died. The cause of his death was declared to have been grip, and the immediate cause hemorrhage. That was the report of a practicing physician who was also a member of the legislature; but we subsequently found, on examining the corpse and taking the testimony of the doctor himself and of the embalmer who prepared the remains, that it was black smallpox, beyond question. Now, when we have such gross errors what are we going to do? We know we are getting the number of deaths, with locations, ages, sexes, etc., but we realize that our returns are woefully deficient as to the causes of death. We see no way out of the dilemma except through the better education of physicians. The teachers of hygiene, as Dr. Egbert has said, must dwell more particularly than before on this matter. They must pound it in and let the oncoming generation know how very important it is to be able to state definitely and exactly the chief and the immediate causes of the deaths that occur in their future practice. Now, when we receive a certificate that is not full and complete we do as Dr. Wilbur related. We do not send the original back, because we would have trouble in recovering it, but we send a duplicate printed in different ink; and we never let up until the physician or officer sends us an answer. We have complete control over our officers, because they can be discharged at any time for not performing their duty. They are on salary, and receive no fees whatever for collecting statistics. Out of our 675 reporting stations, we do not have an average of 12 that fail us each month. We get after them when they are delinquent, and eventually get a report from them before the month is half over. They must report by the fifth of each month, whether they have any deaths in their districts or not. I want to say something about Mr. King's sample law, which I read with some care. It is a most admirable law as a whole. I note he provides penalties for the interment of the dead without a permit, etc. The penalty is a fine of from $5 to $50 on the undertaker or other person who may bury the remains. I do not think that clause is going to make the returns even approximately perfect. A widow's child may die away out in the country. The neighbors come in and lay the body out, some one makes a coffin out of a pine box, and the child is buried without a permit. In such a case you could never enforce the penalty in any justice of the peace's court in the country. In the Indiana law we have a clause that usually brings a report. It provides that in the event of a burial without a permit the coroner must disinter the remains, hold an inquest, secure all possible data, enter the same on the blanks of the board of health, and report the result to the health officer having jurisdiction. There is also a fine of $10 to $100 on any undertaker or other person burying a body without a permit. That can readily be enforced against the undertaker, but not so in the instance I related; though the other clause can be and is enforced. We have had trouble in only a few instances, so severe is the penalty. Let it be done in one county, and the other counties within a radius of five will hear of it and learn the lesson. Then, the coroner is after a fee, and is

likewise in a position where he can plead that he must disinter, that he has no help for it under the law. They get the body out of the ground, summon the physicians who failed to make the report, summon all parties concerned; and after one experience that community never has any more burials without permits. However, as I have said, it is the cause of death that we have trouble with, and I am satisfied we will have that trouble for many years to come.

DR. J. S. FULTON, Baltimore—Many sanitarians dread the difficulties of rural registration. That fear seems to me somewhat exaggerated. What is wanting is a due appreciation on the part of cities and close communities of their dependence, for their own sanitary safety, on the sanitation of rural districts. In Pennsylvania probably 75 per cent. of the entire population are living under registration laws, more or less effective. It is municipal registration, however, leaving the rural districts wholly out of the mortality account. There is an ancient registration law still on the statute books of that state, but useless for want of a burial permit provision. Now, suppose the cities of Pennsylvania should realize that they owe their bad eminence in typhoid mortality to the rural districts. Suppose that Pittsburg and Allegheny, for instance, the worst typhoid cities in their latitude in 1900, should have a strong suspicion that their sources of infection lie in the perennial typhoid of the unregistered adjacent rural districts, could the villagers and rustics possibly defeat a bill which proposed to compel every part of the state to render monthly a full account of its mortality? This consideration would prevail, I fancy, even in Philadelphia, a city which is notorious in its class, but which is in typhoid mortality far exceeded by a dozen lesser cities in the same state. When the cities discover that they draw on the country districts for their supplies of typhoid and intestinal disorders as regularly as for their supplies of food and drink, the demand for registration of mortality in rural districts will be irresistible. Nor do I believe that rural communities object seriously to registration. In Michigan the registration law is not mandatory in areas of less population than 15 per square mile, but such areas are registered nevertheless, and are registered because they desire it. If all the registration data now regularly collected in such states as Pennsylvania and New York were assembled and properly displayed, I believe that 75 per cent. of the population would be found included, and that the advantages of registration would appeal effectively to a majority of the remaining 25 per cent. Such instances as have been cited by Dr. Hurty will inevitably arise. They have no numerical importance. They are easily met by administrative tact, and they need have no influence on the reliability of mortality returns in general. Another point about rural registration is that it is a very good check on municipal registration. Municipal registration is subject to many abuses that would be controlled if it were necessary to record every death somewhere, either where it occurred or at the true residence of the person who has died.

DR. CRESSY L. WILBUR—The question of density of population is most important in drafting the registration law of a state. If you do not have a sufficient supply of local registrars, so people can easily get to the local office, there will be an explosion. In some parts of Illinois, especially the southwestern part, which is sparsely settled, the present law, which was passed in 1890, has proved very obnoxious to the people. The law provides for only six registrars in the counties, in addition to the county clerk. This has proved to be the cause of so much trouble that there are now two or three bills pending to repeal the law for the whole state. The average population to the registrar should not be much more than 500, and the distance should not be over six miles, so that the people can easily get permits; and in that way we will have no violations of the law. I presume this will have to be taken into consideration in Pennsylvania, of which some parts are sparsely settled. It can be done in sparsely settled as well as in well-settled communities.

DR. H. M. BRACKEN, Minneapolis—We have found in Minnesota that it is not much harder to get statistics from the rural districts than from the small urban communities. We have registrars for each township, and many of them make good returns. Minnesota, unfortunately, is not classed with the registration states, although we have laws meant to be complete and thorough. Last winter we asked for a law requiring a burial permit in all cases of death, but the committee on public health was composed of men from the country, and they objected, using the same argument that Dr. Hurty mentioned, with reference to neighbors helping to bury the dead, without the usual formula of undertaker.

THE LIMITATIONS IN THE USE OF ACONITE AND VERATRUM VIRIDE.*

WARREN B. HILL, M.D.
MILWAUKEE, WIS.

Too much has been written on the possibilities or probabilities of the therapeutic value of drugs and not enough regarding the limitations of their use. It is only within a comparatively short time that physicians have relied on their knowledge of the pharmacodynamics, rather than on tradition based on empiricism, to guide them in their use of drugs. Like the rest of mankind, physicians are prone to follow the calf paths of tradition; and the works on therapeutics are full of references to the success of remedies used by individuals of repute, regardless of the known physiologic action of the drugs in question.

A few years ago I was much impressed by a remark of our eminent therapeutist, Dr. John V. Shoemaker, when he said that he had written so much on the therapeutic value of drugs and had taken so much for granted on hearsay evidence that he felt it a duty he owed the profession to write a book on the limitations of the use of drugs.

The size of our pharmacopeia and of our text-books on materia medica and therapeutics seems to be proof that we know too little about a great many drugs and not enough about a few. I quote from a recognized authority regarding the uses of aconite:

Dr. Murchison regards aconite as a remedy of great value for reducing the pulse and temperature in fever, and especially in the pyrexia resulting from inflammation. . . .

Dr. Bomford bears witness to the value of aconite in the remittent fevers of India. . . .

Dr. W. Dobie details four cases of pneumonia in which aconite, in small, frequently repeated doses, apparently cut short the attack. . . .

In puerperal fever, Dr. Playfair (Vol. II, p. 328) regards aconite in minute doses as a most valuable remedy. . . .

In tonsillitis, acute sore throat and in acute catarrh of children, Dr. Ringer strongly recommends the tincture. . . .

In acute rheumatism, aconite at one time was held in high esteem. . . . In rheumatic pains occurring in gouty subjects, Professor Graves has found it very serviceable. The same remark applies to lumbago. . . .

In neuralgia, aconite is a remedy of great value, but its use appears to be restricted mainly to those cases in which all signs of active disease are absent or have been subdued by other means. . . .

In sciatica, Dr. Fuller concludes that it proves a valuable and efficient remedy in many obstinate forms of the disease. . . .

Toothache is sometimes speedily cured by rubbing the gums with a few drops of the tincture. . . .

In tetanus the use of aconite in large and repeated doses was first proposed by Mr. De Morgan, who relates several cases illustrative of its efficacy. . . .

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. S. Solis-Cohen, George F. Butler and N. S. Davis, Jr.

In diseases of the heart, in which the chief indication is to diminish vascular excitement or irritability of that organ, aconite proves in the highest degree serviceable. . . . Even in pericarditis, when the heart throbs violently and thus produces extreme pain, aconite, according to Dr. Ringer, will quiet the heart and speedily ease the pain. . . .

In erysipelas, aconite was a favorite remedy of Liston. . . . To painful sprains and bruises and chronic arthritic swellings, lin. aconiti, locally applied, often affords speedy relief. . . .

In amenorrhea, Dr. Copeland prescribed the extract with decided benefit; and Dr. Ringer states that in sudden suspension of the menses, as from a cold, it may be employed with advantage; he likewise states that the acute stages of gonorrhea may be well treated with gtt. j. of the tincture every hour, and that the same treatment will often remove chordee. For the relief of severe uterine pains lin. aconiti externally applied occasionally affords relief when other remedies fail. . . .

Thus you see the novice might imagine that he was fairly well equipped to deal with nearly all human ills with this single drug. Is it strange, then, that with such brilliant promises, and after disappointments that must surely come, he should become a skeptic in medicine, and declare that he does not believe in the use of drugs?

Aconite and veratrum viride are old drugs and came into use when disease was little understood, when fevers were regarded as diseases and not mere symptoms of disease. The high temperature and rapid pulse were the abnormal conditions to be remedied, and it appeared perfectly rational to employ aconite and veratrum viride. They headed the list of drugs employed in the treatment of sthenic fevers, such as pneumonia, and it was thought that a great stride had been made in medicine in the supplanting of blood letting by the internal use of aconite and veratrum viride. And it was a move in the right direction, not because there was any real advantage in depressing the heart by the use of aconite, or of depressing it by venesection, but because it called the attention of the profession to the fact that it was necessary to conserve the energy of the patient in order that recovery might be insured. While, since the days of antiseptics, we have sometimes wandered away from that truth and have destroyed our patients in our attempts to exterminate microbes, we have always returned; and to-day it remains one of the fundamental principles in the practice of therapeutics.

PHYSIOLOGIC ACTION.

I know of no recent work having been done with aconite or veratrum viride and will, therefore, not go into the physiologic action any more than to summarize what is already well known.

The primary action is stimulation of the peripheral nerve endings; causing a tingling sensation, produced either locally or systemically; stimulation of the vasomotor mechanism, resulting in arterial constriction and slight diuretic effect; powerful stimulation of the respiratory center.

The secondary action is paralysis of the over-stimulated peripheral nerves, causing anesthesia; pronounced depression of the heart, which is augmented by the effect on the vagus; lowering of the blood pressure; and reduction of temperature, which is due at least partly to increased evaporation from its diaphoretic action.

The promptness of the secondary effect is dependent on the size and concentration of the doses given. A very little aconitin is eliminated, as such, from the system, the greater portion being decomposed or burnt up in the system.

The action of veratrum viride is so similar that it does not call for a separate recital.

The indications, then, for the use of these drugs are: To relieve pain, reduce temperature, promote diaphoresis, slow the heart and reduce blood pressure.

As the analgesic properties of the aconite are not manifest until after the appearance of the secondary or toxic symptom of the drug, it is a dangerous remedy to use, and we have such remedies as phenacetin, which is more powerful and less dangerous. As a diaphoretic it does not compare with Dover's powders or pilocarpin. As an agent to slow the heart it is far inferior to digitalis, strophanthus or spartein, as they slow the heart by lengthening the diastole, thus favoring the recuperation of that organ.

Blood letting is probably a more efficient remedy for the lowering of arterial tension than either aconite or veratrum viride, as by this process the toxins are diluted and the volume of blood may be readily restored by saline transfusions.

Finally, I do not believe that we are justified, with out present knowledge of the etiology of disease, to apply remedies solely for the reduction of fever. If the cause of the fever is not known or can not be directly attacked, our efforts should be directed toward supporting the patient, the stimulation of those cells which are potent in the production of antitoxins, etc., or the lessening of oxidation and waste by lowering metabolism; and then if it becomes necessary to reduce the temperature *per se*, hydrotherapy has proven itself to be a safe and efficient agent.

In conclusion, I would say that I do not wish to be understood as saying that aconite and veratrum viride are absolutely useless or prohibitively dangerous, but that there are other remedies which may be used with greater safety and with equally good or better effect.

Should one wish to use aconite or veratrum viride, however, for the primary action, it should be given in exceedingly small doses, well diluted and repeated at short intervals.

DISCUSSION.

Dr. F. R. Weber, Milwaukee, Wis.—There are portions of the United States in which these two drugs are used, but in the northern part of the country they are hardly known in the shops. They are depressants, and that is their limitation. To-day we go back and study the heart more than the old physician used to do—we study the heart as a muscular organ. That grand old physician of Dublin who first introduced the knowledge of the heart muscle as an organ of itself is a man we must consider to-day. The acute diseases, such as typhoid and pneumonia and septicemia, in which it takes weeks and months for the patient to recover, are the diseases in which aconite used to kill. We have toxins which have their effect primarily on the heart muscle; we have degeneration going on which is peculiar to the heart muscle, a degeneration that extends beyond the muscular fiber and goes into the intracellular tissue; it is an interstitial inflammation of the heart which weakens the patient to such an extent several weeks after typhoid or pneumonia that we have to look very carefully to the conservation of the heart. The infectious diseases have a tendency to weaken the heart in the third week of convalescence. If, then, we weaken the heart during any period of the disease what shall become of the heart during convalescence? I think we do harm, not in the stage of action, but when the heart needs all of its recuperative power.

Dr. H. A. Moody, Mobile, Ala.—I am surprised to hear the action of veratrum viride and of aconite described as identical. In the southern part of the United States veratrum is more popular than anywhere else, and we consider that

there is an immense difference between the action of veratrum and aconite. I am tempted to ask the question whether any one here can tell me the fatal dose of veratrum viride. Can any one here point to the record of a death from that so-called poison? Do any of the text-books mention the fatal dose or tell of a death? There may be such, but it has escaped my attention. We have in veratrum viride a depressant which can be given in small doses of two or three drops until the number of pulsations and the force of the heart are reduced and the patient is relaxed and in perspiration. On the other hand, it is a demonstrated fact that you can administer twenty or thirty drops of the same drug hypodermically, and repeat in an hour or two in cases of puerperal eclampsia and yet not poison the patient. That is on record. You can handle veratrum that way, and, therefore, I do not think you should bring it under the same indictment as aconite. I do not consider it the most desirable form of treatment in wasting diseases, and only rise to insist that there shall be a difference drawn between the two drugs.

Dr. W. J. Robinson, New York—While aconite and veratrum viride are not used as much as formerly, they are very valuable drugs. For instance, in the first stage of sthenic pneumonia there is nothing to equal a few doses of aconite. I make the same objection as does Dr. Moody to classing them together. Aconite is a very dangerous drug, while veratrum has nothing on record against it. In large doses it produces emesis, but that is the worst it does. The value of veratrum in puerperal eclampsia can not be overestimated. I have collected a very large number of cases, and the best results are obtained by giving veratrum in large doses, and this without any bad effects. This question was brought up last year and the same objection was made that these two drugs should not be classed in the same category. While both are cardiac depressants, veratrum is a much safer drug. Gilardoni's clinical and experimental reports show that in veratrum viride we have the safest drug when we wish to reduce arterial tension and keep it reduced for a considerable length of time.

Dr. W. W. Tompkins, Charleston, W. Va.—I am somewhat of a "middle-of-the-road" man on this particular question. I think, however, that in a large measure we allow our prejudices to influence us in the use of drugs. When I was a student my materia medica teacher did not like aconite because it was used by a homeopath. I believe that aconite is a depressant of the respiratory center more than of the heart. However, it is a mistake to prescribe it in small quantities for any length of time, though it is not my observation that aconite exercises influence for any length of time. I have not looked into the statistics of the mischief done by these two drugs, but aconite poisoning is not infrequent. In the Virginia Lunatic Asylum at Stanton some 12 or 15 patients were poisoned by aconite and died, and it is still an unsolved mystery. On the other hand, I believe each of these drugs has its limitations and its uses. I do not know from experience much about veratrum; it seems to be less frequently used than aconite. I do not know of any fatal cases from its administration. I know those who use it often speak in extravagant praise of its efficacy in certain diseases. I hope the remarks made here will result in a more thorough study of the drug.

Dr. C. S. Chamberlin, Cincinnati—Dr. A. B. Isham[1] has reported a large number of cases of eclampsia, pneumococcus infection, convulsions, uremia, carbolic acid poisoning, etc., in which he used veratrum viride as an eliminant hypodermically and in very large doses. If emesis or relaxation did not occur within 15 minutes, the dose was repeated, sometimes a second time. Veratrum viride in large doses produces copious diuresis, emesis and catharsis.

Dr. G. D. Kahlo, Indianapolis—It is my understanding that the essayist did not intend to classify the two drugs as having identical effects. In my part of the country both drugs are used to a limited extent, but they have been recommended too indiscriminately. We find, too, that the revised authorities recommend them in smaller doses.

Dr. Hugh N. Leavell, Louisville, Ky.—Taking into consideration the manner in which Dr. Hill presented this paper, it is not surprising to know that the homeopaths selected this remedy as one on which to build a reputation. I am glad Dr. Hill presented the matter in just that way: "The limitations in the use of" the drugs. I believe we should specialize as much as possible and try to draw a line in each particular case and administer the drug to meet the indications as they arise, taking into consideration any idiosyncrasy shown by the patient. The effect on the blood pressure is well shown, and here we find the best use for aconite and here we get the best results. We must take into consideration the probable absorptive power of the epithelium to which it is applied and we must not lose sight of the fact that it is a very toxic drug and can produce death by its toxic effect on the heart muscle.

Dr. Solomon Solis-Cohen, Philadelphia—When Bartholow came to Philadelphia, twenty-odd years ago, he was very much laughed at because he advocated the use of nitroglycerin: but nitroglycerin has saved a great many lives since Bartholow began to force it on the attention of the profession. There certainly must be some foundation for the general advocacy of veratrum. I agree with Dr. Robinson that there is a time, in the very beginning of sthenic pneumonia, when aconite will do more good than anything else in the pharmacopeia, but we do not often see cases at that time. From the reports quoted by the essayist it would appear that aconite is to be used in the beginning and also at any other time. It is just such careless statements, which he properly reprobates, that mislead us and shock our faith. A routine use I have for aconite—I have not seen it mentioned in the text-books—is in the treatment of many cases of mitral stenosis, in which the heart is pumping tumultuously, trying its best to push the blood through a narrow mitral opening, and yet the effort is ineffectual, the pulse being thin and weak. In such cases it is well to depress the overexalted function to the level of the impaired function in an effort to re-establish physiologic equilibrium. With an overacting heart and a weak and thready pulse, aconite given in very small and successively diminishing doses, continued over a long period of time, has, in my observation, done much good. I have in mind two boys who came under my care at the same time—about twelve years ago. They are now grown, active men, students and teachers. They are not conscious that their hearts are impaired, and for many years have taken no medicine. It is true that iron was administered in conjunction with and after the aconite, and that their general hygiene was regulated.

Dr. W. B. Hill—I call attention to the fact that I changed the title of the paper purposely. The subject was chosen for me, otherwise I would have preferred to take one drug only. I did not regard aconite and veratrum viride as dangerous from the viewpoint of acute poisoning, but in just the conditions which Dr. Weber brought out: that the heart is ultimately poisoned, not by the aconite or the veratrum itself, but by the lack of proper blood pressure which is the life of the heart, and therefore I say that those drugs which reduce the blood pressure in disease unnecessarily, while they may have no immediate bad result, must ultimately bring about a diseased condition to a greater or less extent. I did not intend to take up all the uses of these drugs, as that was not within the scope of the paper. The use of veratrum in eclampsia has been spoken of and recommended, but one so doing gave the physiologic reasons for it. The criticism is, although you use it successfully, why did you use it? In eclampsia it is used because of its power to relax and lower the blood pressure. In this connection I will call your attention to pilocarpin which, in addition to lowering blood pressure, causes a greater elimination of retained products than any other remedy. The only trouble with the use of pilocarpin is that it is not used in sufficiently large doses, and yet if a death occurs after the use of pilocarpin the death is attributed

1. "Veratrum Viride as an Antitoxic," Medical News, Jan. 10, 1903.

to pilocarpin when, in fact, the death followed because not enough pilocarpin was used. I was taught to give Norwood's tincture in pneumonia because there was little danger of acute poisoning. I got over that. Opium will relieve the patient by producing a diaphoresis, yet we do not always give opium simply because we want to render the patient more comfortable. So I believe that aconite in the beginning of pneumonia, where the heart has more than double its burden, is contraindicated because of the ultimate effect of the drug on the heart.

NON-TUBERCULAR HEMORRHAGES OF THE AIR PASSAGES.*

LAFAYETTE PAGE, A.M., M.D.

Professor of Diseases of the Nose and Throat, Central College of Physicians and Surgeons; Consulting Surgeon on Diseases of the Nose, Throat and Ear, City Hospital and Dispensary.

INDIANAPOLIS.

The great vascularity of the mucosa lining the respiratory tract, with its delicate epithelial coverings and its close sympathetic connections through its vasomotor system with the rest of the organism, renders it exceedingly vulnerable to atmospheric conditions and to blood changes and blood pressure from within the organism. The blood vessels supplying this great stretch of mucous membrane are affected by every atmospheric condition, such as thermic and barometric changes, parasitic irritations, dusts and pollens, noxious gases, and all the filth that saturates the atmosphere from many sources. All these forms of irritation disturbing the normal functions of the membrane produce hyperemias, destroy the epithelial coverings and set up morbid processes which weaken the vessel walls and are thus important etiologic factors in the production of hemorrhage. In addition to these atmospheric causes from without, we have the various forms of traumatism to which the anatomic structure of the respiratory tract is exposed, such as concussions, contusions, fractures, dislocations and the many kinds of surgical procedure for the correction of abnormalities, deformities, removal of growths and mechanical irritation of foreign bodies lodged in the respiratory tract. Severe hemorrhages which often result from surgical operations are usually due to some constitutional diathesis or to some anomaly of the circulation in the part operated on.

CONSTITUTIONAL CAUSES OF HEMORRHAGE.

On account of the close reflex relationship between the upper respiratory tract and the pelvic organs it has often been observed that any changes taking place in the latter produce vasomotor changes in the nose and throat. The rapid development of the larynx at puberty is always attended by marked hyperemia. The erectile tissues of the nose show marked engorgement at this period and are especially prone to hemorrhage. Since J. McKenzie, Hack and others have called attention to the close blood relationship of these parts in their physiologic and pathologic changes, we are enabled to treat many cases of hyperemia of the nose and throat with a greater degree of success.

Fleiss has shown by an extensive series of investigations in the gynecologic clinic of the University of Berlin that there are certain points on the anterior extremity of the middle and inferior turbinate bodies, designated by him the "genital areas," through which influence can be exercised in pathologic conditions of the female pelvic organs. By cocainizing the genital areas the pains which accompany or follow the menstrual flow can be relieved, and labor pains can be reduced to a minimum, while by cauterizing these areas a permanent cure of many cases of dysmenorrhea may be achieved.

The writer has had an opportunity of observing in several cases the effect on dysmenorrhea of treatment administered through the genital areas of the turbinates, and also two cases of vicarious hemorrhage, one from the erectile tissues of the nose and the other from the larynx, as the result of sudden arrest of the menstrual flow. There are many interesting cases reported of vicarious hemorrhage from the nose and throat in the literature of the subject. The case of Alibert, in which sudden stoppage of the menstrual flow caused a fatal hemorrhage from the nose, and the case of Kussmaul, quoted by Bosworth, in which there was a periodical nasal hemorrhage in a woman with total absence of uterus; also one by Fricher of a girl of 19 who had never menstruated, but who had violent hemorrhages from the nose at regular intervals of six weeks, which finally proved fatal.

There are a few reports of cases of vicarious hemorrhage due to the arrest of long existing bleeding from rectal hemorrhoids, and from sudden checking of the functions of skin and the cure of certain skin diseases. Bleeding from the nose or larynx during pregnancy is a not uncommon occurrence, probably due to the pressure of the uterus on the large abdominal veins. All of the diseases of the liver, spleen, kidneys, heart and brain which obstruct the return flow of the blood, produce engorgement in the respiratory tract and tend to produce hemorrhage. "We often see persistent hemorrhage from the nose and larynx in cirrhosis of the liver and in renal disease, and it is often associated with the cardiac disease in the venous stases due to failure of compensation in mitral diseases and in aortic insufficiency." (Friedreichs.)

Edgren says that hemorrhages of the air passages are frequent in the presclerotic period and, in the elderly, point to incipient arteriosclerosis. In these cases the bleeding comes on without apparent cause, or it may follow any violent emotion. Any increase of blood pressure is liable to cause rupture of the weakened vessel walls in this disease. The association between the veins of the interior of the skull and the venous sinuses of the nose is so intimate that all the congested states of the cerebrum and meninges are liable to produce epistaxis. Tracheal hemorrhages are comparatively rare. We have an occasional case of fatal hemorrhage from this source due to rupture of an aneurism of the aorta into the trachea. This is due to ulcerations between the rings from pressure of the aneurismal sac. Five cases of tracheal hemorrhage following influenza are reported by Donelan.[1]

HEMORRHAGE DUE TO THE ACUTE FEBRILE DISEASES AND HEMORRHAGIC DIATHESIS.

Hemorrhages occur as a premonitory symptom or as a concomitant of many of the epidemic fevers, such as typhoid and remittent fever, scurvy, diphtheria and the exanthemata. The cause of the hemorrhages in these fevers is yet obscure. They usually occur from the respiratory tract in the initial stages of these affections, and it is the accepted opinion among pathologists that they are due to yet undiscovered changes in the blood and blood vessels of toxic origin.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

1. Jour. of Laryngol. and Otol., January, 1901.

Nichols claims that in some cases the appearance of hemorrhage corresponds to secondary infections and in others to the cachectic state to which patients are reduced. In the early stages of these affections we find the membrane of the nose and throat intensely hyperemic, and in the later stages a breaking down of the epithelium and vessel walls, with small ulcerations and extravasations of blood.

The hemorrhages of typhoid fever, according to Friedreich, show a predilection for the septum, but may occur in other parts of the mucous membrane. Superficial ulcerations causing hemorrhages are very common in certain regions of the pharynx and larynx. They are commonly found on the faucial pillars, the free border or laryngeal surface of the epiglottis, the aryepiglottic folds, and often occur below the glottis. They are rarely seen on the vocal cords.

Millet observed: "Epistaxis associated with malarial infections is intermittent or periodical, and may be controlled by quinin."

Of all the predisposing causes of hemorrhages hemophilia occupies the first place. It is the "bête noire" of the laryngologist. There are but few of the operators in this department of surgery who have not had sad experiences with this class of patients known as "bleeders." Reports of fatal hemorrhages from excision of the tonsils and adenoids in patients unsuspected of having this predisposition come up before almost every meeting of laryngologists.

The cause of this diathesis is yet undetermined. Statistics show that it has a decided preference to lay its mark on the males. Among the "bleeder" families the females are usually exempt. Among the spontaneous hemorrhages due to hemophilia, epistaxis is by far the most common form. According to one authority, among 236 hemorrhages of various kinds 122 were from the nose, and Eichhorst says: "These hemorrhages are usually preceded by perversion of the senses of taste and smell. One patient could smell, another taste, the approach of his hemorrhage." Ecchymosis and submucous hemorrhages in the larynx, as well as ulcerations of the pharynx and larynx, are very common in purpura hemorrhagica.

SYPHILIS AS A CAUSE OF HEMORRHAGES.

Syphilis is not regarded by most of the authorities on the subject as a frequent cause of hemorrhage. In the primary and secondary stages hemorrhages are very rare. In the tertiary and hereditary forms they are much more frequent and are often very severe. It would seem that syphilis would play a most important rôle in the production of hemorrhage from the respiratory tract on account of its predilection for these parts and the destructive changes which are so often wrought here by this disease. It seems that the ulcerative processes rarely invade the blood vessels in syphilis.

LOCAL CAUSES.

Among the local causes of epistaxis, deflections of the septum should occupy first place. The irregularities on the deformed septum expose the superficial capillaries to many forms of irritants in the air current which denude the vessel walls and thus bring about more or less violent attacks of hemorrhage (Bosworth).

The various forms of neoplasms of the nose, pharynx and larynx, such as fibroma, sarcoma and carcinoma, are often the source of most alarming and difficult hemorrhages to control.

THE MOST FREQUENT LOCATIONS.

"Since the time of Valsalva, a point on the anterior portion of the cartilaginous septum has been known as the most common site of hemorrhage from the nose." Bleeding from this point is rarely dangerous, and is usually easy to control. In hemophilia and purpura the bleeding comes from various points on the mucous membrane. In profuse hemorrhage the bleeding point is difficult, and sometimes impossible, to discover. The ethmoidal veins are often the source of violent hemorrhage, probably on account of their close connection with the cerebral circulation. Other points on the posterior ends of the lower turbinates, the venous plexus in the vault of the pharynx and the venous plexus at the base of the tongue, are frequent seats of hemorrhage. Bleeding from the larynx is comparatively rare, and is not often of a dangerous character from the loss of blood. "Laryngeal hemorrhages are dangerous only when they are beneath the mucous membrane, thus producing hemorrhagic edema and impending asphyxia." They may easily be mistaken for hemorrhage from the lungs or hematemesis.

PROGNOSIS.

Bleeding from the nose is rarely fatal. In many cases it seems to be Nature's method of relieving overdistended blood vessels. There is no doubt that many cases of cerebral apoplexy are averted by nasal hemorrhage, and it is quite common for some patients to experience immediate relief from a severe congestive headache by a free nose bleed. Spontaneous hemorrhages are more dangerous in young children and the aged on account of the friability of the vessel walls. Fatal hemorrhages of the upper respiratory tract are reported in children under a month old from hereditary syphilis. "Swoboda reports four fatal cases of nurslings from hemorrhages of the upper air passages. In all of his cases the bleeding had not appeared externally, but had passed by the nasopharynx into the stomach." (Sajous' Annual.)

J. N. McKenzie says: "Persistent and recurrent epistaxis is much more frequent between the ages of 15 and 25 years." The greatest number of fatal hemorrhages come, perhaps, from the removal of the tonsillar and adenoid tissues among those of the hemorrhagic diathesis and those with anomalies of the circulation in these tissues.

DIAGNOSIS.

The importance of a correct diagnosis in hemorrhage of the upper air passages can not be overestimated. Every mechanical means should be exhausted in determining the exact location of the bleeding point. Modern apparatus has been so perfected for diagnostic purposes that no one is justified in assuming to give an opinion in these cases who has not availed himself of the best apparatus and acquired the best skill possible in their use. The laryngeal mirror and palate retractor are invaluable aids in locating and differentiating diseases of the whole respiratory apparatus, and in many cases of the digestive apparatus as well.

ILLUSTRATIVE CASES.

Hemorrhages of the larynx, the nasopharynx, the tonsillar tissues, and the region about the base of the tongue are often mistaken for pulmonary hemorrhage, or hemorrhage of the stomach. The following cases in the writer's experience would tend to emphasize the importance of a patient effort with these instruments (the laryngoscope and palate retractor) in the search for the bleeding point.

CASE 1.—A young attorney of splendid physique called on me for what he supposed were hemorrhages from the lungs. He had been spitting blood for two or three weeks. I could discover no evidence of lung disease by the most careful examination. There was slight hyperemia of the larynx, but no sign of hemorrhage from that source. The anterior ends of the turbinate bodies were considerably engorged, producing occlusion of the nares. The first examination of the post-nasal space, on account of the patient's excessively sensitive reflexes, was unsuccessful. On questioning him he most skilfully evaded any history of syphilis. I remained in darkness as to the source of hemorrhage until I succeeded in examining the post-nasal space with the use of the palate retractor. The posterior portion of the septum was completely necrosed, the ulcerated process having extended to the veins in the vault of the pharynx. The hemorrhage that had persisted and was apparently from the lungs soon yielded to syphilitic treatment.

CASE 2.—I obtained the following history from Dr. Graham of Indianapolis:

"I was called to see Mr. E., aged 24, at St. Vincent's Hospital, Oct. 10, 1902. He had suffered a profuse hemorrhage from the mouth and nose as he was about to alight from a train at the Union Station. I obtained the following history: The patient, so far as he knew, had enjoyed good health until two months previous, when, while in a New York theater, there occurred without any premonition whatever a hemorrhage, the blood flowing from both the nose and mouth. He was removed to the New York Hospital, and one week later suffered a similar hemorrhage. He stated that it became necessary for the physicians to resort to intravenous injections of salt solution. . . . His case was there diagnosed as one of gastric ulcer, and laparotomy was performed for the same. One week later a third hemorrhage occurred. It was one hour after the fourth hemorrhage occurred that I was called to see this patient. It was stated that this hemorrhage filled a large cuspidor, and I am inclined to believe that this statement is not an exaggeration because of the hemorrhages which I saw at a later period.

"The diagnosis of gastric ulcer was not clear to me in this case and yet I placed my patient at complete rest, withheld all food by the mouth, and placed an ice bag over the epigastric region. . . . Dr. Page was called in consultation, and will give the further history and treatment of this most interesting case. I might add that I wrote Dr. J. H. Lewis, hospital surgeon at the New York Hospital, regarding this case, stating in my letter that I did not think there were any signs or symptoms of gastric ulcer, and received the following letter in reply:

" 'Mr. E. was a patient at this hospital and was operated on, as he stated to you. His stomach was opened by a two-inch incision in the anterior wall very near the pylorus. A bleeding surface one-half by three-fourths of an inch was found about the middle of the anterior wall and united by mattress sutures of chromated gut. It was thought it had probably been caused by instrumentation, and was not the cause of the previous hemorrhages. Apart from this no ulcer was found. One week after the operation he vomited about one quart of blood. He was discharged in fair condition with the diagnosis still in doubt. One remarkable feature at the operation was profuse and persistent bleeding in the wound through the abdominal wall.' "

I was called in consultation by Dr. Graham to locate, if possible, the seat of hemorrhage in this case. He had suspected that the bleeding was from the throat. Owing to the nervous and exhausted condition of the patient from the great loss of blood, and to the narrowing of the isthmus of the fauces from adhesion of the anterior pillars of the fauces to the dorsum of the tongue, I found it very difficult at the first examination to get a satisfactory view of the larynx and post-nasal space. We put the patient on strychnia and after a few days' training I succeeded in getting a good view of the throat in the laryngeal mirror. I discovered at the base of the tongue two deep fissures about an inch and a half long, extending from either side of the epiglottis and cutting the venous plexus about the base of the tongue, coming together and forming an acute angle about an inch above the free border of the epiglottis. The tissue included in this triangle about the root of the tongue was considerably excavated. In examining these fissures with a probe a profuse hemorrhage was started and I had to resort to the suprarenal extract and chromic acid to arrest it. I was satisfied from this examination that this had been the seat of the previous hemorrhages which had so greatly exsanguinated the patient. On discovering these ulcerated fissures and the adhesions between the pillars of the fauces and the tongue (which caused the patient to talk tongue-tied), I concluded that syphilis was the cause of the trouble, although there was absolutely no history to confirm it. I placed the patient on antisyphilitic treatment and applied chromic acid and later nitrate of silver to the ulcerated surfaces. The hemorrhages ceased at once and there was a rapid gain in strength and weight from the start.

CASE 3.—Miss C., aged 23 years, a singer, called on me in June, 1895, for what she supposed were pulmonary hemorrhages. She said the sputum had been examined and that her physician found tubercle bacilli in abundance, and ordered her to Colorado at once. Laryngoscopic examination revealed a small angioma on the left vocal chord surrounded by dried blood. I cleansed the larynx with the spray and could see that the blood vessels about the small growth were dilated and partially denuded of epithelium. She said her hemorrhages usually came on after singing. I requested her to sing, and could detect the blood flowing from the growth and the dilated vessels. I destroyed the distended vessels and the growth with the electro-cautery and there was never any further hemorrhage. The subsequent history of this case and the lack of abnormal temperature, as determined by several tests with the thermometer, convinced me that this patient never had tuberculosis, notwithstanding that tubercle bacilli were reported to have been found in the sputum.

TREATMENT.

It is the intention of the writer to only refer in a few words to some of the numerous methods of treating hemorrhages of the respiratory tract. With our modern method of illuminating the air passages the bleeding point should be located before any efforts at plugging or hemostatics are resorted to for the checking of the hemorrhage. In only exceptional cases where the bleeding is from several different points on the membrane and in those cases where gagging and vomiting render the parts inaccessible should we try to check the flow of blood temporarily until its source can be determined.

The cocain spray and suprarenal extract have proved to be invaluable aids in checking the flow of blood and diminishing the reflexes, thus enabling us to make a diagnosis. The ordinary surgical measures for checking hemorrhages in other parts, such as the use of the ligature and artery forceps, are rarely of service to the laryngologist. Probably in no department of surgery is the operator so handicapped in the treating of hemorrhages as in the nose and throat. Large blood vessels emerge from bony or cartilaginous walls to be distributed to parts accessible only by the most delicate instruments and visible only by artificial lights. To cut down on a vessel and ligate it is out of the question in the majority of cases. In a few cases this has been done successfully in the violent hemorrhage that sometimes follows the removal of the tonsils or adenoids. Keane reports two cases of ligation of the external carotid artery for severe hemorrhage following slight operations in the nose and pharynx. He says this is a simple operation, and every nose and throat surgeon should be prepared to perform it when life is threatened.

For the ordinary hemorrhages of the respiratory tract our resources are ample and effective. Suprarenal or adrenalin extract has proved invaluable in the writer's operative work.

Some laryngologists claim that it is deceptive in that it is apt to be followed by intense reaction and secondary hemorrhage several hours after an operation.

GENERAL SURGICAL ANESTHESIA.

ERNEST J. MELLISH, M.D.
Surgeon to Hôtel Dieu (Sisters' Hospital).
EL PASO, TEXAS.

(Concluded from p. 1403.)

SELECTION OF AN ANESTHETIC.

In order to receive favorable comparative consideration, an anesthetic should possess these qualities: Immediate and remote safety; least disagreeable to take; best calculated to quickly produce and maintain muscular relaxation, followed by the minimum of ill effects, as vomiting, depression, respiratory troubles, renal disturbance; minimum influence on the question of hemorrhage; best adapted to the individual case. In the vast majority of cases the choice lies between ether and chloroform. It has been proven beyond reasonable doubt that, all things considered, chloroform is more dangerous than ether, both immediately and remotely. The immediate safety (during administration) is so overwhelmingly in favor of ether that I do not hesitate to assert that those who hold to the contrary can not be fully acquainted with the facts. There are really very few contraindications to the use of ether when skilfully administered by the "open" method. It is not strongly contraindicated, even in ordinary cases of chronic nephritis, nor in any but acute or severe bronchial affections. In the presence of asthma or of acute bronchial affections, marked arteriosclerosis or atheroma, ether is more dangerous than chloroform, as a rule. Atropin will, to some extent, prevent the danger in the first two conditions, and amyl nitrite or nitroglycerin in the last two. Although formerly (for ten years) a chloroform advocate, I have learned from experience, careful observation, and the study of recent investigations, to use chloroform only where it is especially indicated—and that is extremely seldom. The safety margin between sufficient ether for anesthesia and the lethal dose is much greater than with chloroform. Ether is much safer for indiscriminate use, in that most physicians who administer anesthetics are relatively unskilled in their use. In order to reduce the bad effects of an anesthetic to the minimum, it must be skilfully administered; and when the anesthetic is badly given, the dangers from chloroform are very much greater than those from ether. Ether kills slowly, generally by its effects on respiration, and usually gives ample warning of danger, since the heart continues to beat long after respiration ceases. Chloroform kills quickly, generally by its effect on circulation, and is very likely to afford no warning of danger. Ether is safer in healthy persons than in the weak and prostrated, while chloroform is often as dangerous in the vigorous as in the debilitated. Treatment usually promptly overcomes unfavorable symptoms from ether, and often does no good in those from chloroform. Public opinion in most parts of this country is overwhelmingly in favor of ether, as compared with chloroform; hence, if an accident happens with ether the surgeon is much more likely to escape blame. As mentioned by Treves,[22] the objection urged against ether, that it produces venous engorgement, and, consequently, too much oozing from the field of operation, is not well founded, the question being chiefly one of administration.

22. Practitioner, London, October, 1896.

General Statistics.—The statistics of deaths from anesthetics can not be relied on as indicative of the actual dangers encountered. They represent the deaths only, and not the narrow escapes. Moreover, in this country, and in some others, it is probable that not half the deaths from anesthetics are reported.

The statistics presented at the Thirtieth German Surgical Congress, Berlin, May, 1901, credit chloroform with a death rate of one in 2,023; ether, one in 5,090; ethyl bromid, one in 5,228.

Gurlt's statistics up to 1893, based on 157,815 war cases, give a death rate for chloroform of one in 2,899; chloroform with ether, one in 41,181; ethyl bromid, one in 4,588; pental, one in 199. No deaths from ether or A.C.E. mixture reported.[23]

A. I. Bouffleur[24] quotes statistics of over 1,000,000 chloroform and over 500,000 ether anesthesias, in which the average chloroform mortality is one in 3,355, and the average ether mortality one in 16,768.

In considering statistics, we find that the personal equation is of the greatest importance. One man has 15,000 chloroform cases, with only one death, while another has three deaths in less than 1,000 cases. One selects his cases for chloroform, while another gives it indiscriminately. One administers an anesthetic carefully by the open method; another gives it carelessly by the closed or the smothering method. It is notable that by far the greater number of deaths are reported from localities where chloroform and pseudo-scientific, complicated inhalers are extensively employed. I quote from an article in *The British Medical Journal* of the late '90's: "In a certain institution in Great Britain, in the course of a recent year, there were, out of some 3,000 or 4,000 administrations, no fewer than twelve fatalities from chloroform." Taking the higher number of anesthesias, this means one death in every 333 administrations.

German statistics during the decade 1890 to 1899, show deaths about as follows:

Ether, one in 7,000; chloroform, one in 2,000; ethyl bromid, one in 4,000; pental, one in 2,000; chloroform-ether, one in 9,000; A.C.E., one in 6,000.

Ziegler's statistics give the death rate of chloroform as one in 1,900 and of ether as one in 26,000.

Chaput gave it as one in 2,000 and one in 13,000, respectively.

Foy's statistics, based upon 877,507 chloroformizations and 314,738 etherizations, give a mortality of one in 4,301 and one in 14,987, respectively (Sajous' Annual).

Poncet had but one death in 29,000 ether anesthesias. He believes the danger is from asphyxia.[25]

In the presence of postnasal adenoids, especially if hypertrophy of the faucial tonsils also be present, I consider chloroform extremely dangerous. Nitrous oxid—with the patient in the recumbent posture—is the best anesthetic for these cases, and ether, to the stage of primary relaxation, the next best.

Many of the sudden deaths under anesthesia, especially of children and young persons, have occurred in the presence of a persistent, or even hypertrophic, thymus. In most of such cases the spleen and tonsils are unusually large, and enlargement of the follicles at the base of the tongue is constant (L. Laquer, Strassburg).

Preparation.—All patients who are to be subjected to anesthesia should, if possible, have the benefit of at least two or three days' preparatory treatment and observation. The organs of elimination—the bowels, the kidneys and the skin—should be put in the best possible condition. The urine should be examined carefully for evidences of nephritis or diabetes, so that precautions may be taken where necessary. The condition of the cardiovascular system and of the lungs should be carefully determined, and the patient's habits, as to alcohol, tobacco, and narcotics, inquired into. In patients with any pronounced symptoms of anemia a blood examination should be made. When the percentage of hemoglobin is under 40, no operation should be performed save in great necessity, on account of the destructive action of anesthetics on the erythrocytes. The food for as long a time as possible before the operation should be of the most nutritious and easily digested kind suitable for the patient, and the feeding should be rather forced than otherwise, especially in delicate persons, up to the day preceding the operation, in order to bring the vitality to the highest available point, thus enabling the patient to better withstand the shock of the operation and the anesthetic. The day preceding the anesthesia the diet should be nutritious and light—either liquid or semiliquid. No solid food or milk should be given within several hours of an anesthesia, but water should be allowed to within say two hours preceding it; and a cup of beef tea or one of coffee, or both, taken from one to two hours before the administration, are valuable for their stimulating and sustaining effects. The system should be well supplied with fluids before and after anesthesia. "All the functions of the body are carried on in a fluid medium." Without abundance of this medium, we may not expect as rapid recovery from the effects of the anesthetic and operation as can be obtained with plenty of it.

W. A. Briggs[26] advocates the use of oil of peppermint or menthol preliminary to etherization. About a dram of the oil or of a 50 per cent. alcoholic solution of menthol is sprinkled in the inhaler and the patient allowed to inhale freely for three minutes, then etherization is pushed as rapidly as is consistent with safety. The seeming advantages, as compared with the usual method, are: 1. The anesthesia may be more easily and quickly induced, and more smoothly maintained; 2, entire absence of coughing and suffocation, and comparative freedom from nausea, vomiting and retching; 3, suppression or marked abbreviation of the period of excitement; 4, profounder first anesthesia, which permits minor operations with greater certainty; 5, less post-anesthetic nausea.

During the past few months this method has been followed in my practice with excellent results. It deserves extensive trial. In etherizing a 4-year-old boy, recently, the transition from peppermint to ether was unnoticed, and there was no stage of excitement.

Administration.—It is of the utmost importance that before beginning the administration of an anesthetic the anesthetizer gain the confidence of the patient, and thus be enabled to allay fears which have been conjured up perhaps days or weeks in advance. In persons of average intellect and education the difficulties are not generally great, but in the ignorant, especially if very nervous or hysterical, it is occasionally impossible to allay the apprehensions of real or imaginary dangers. I find that the greater the fear preceding anesthesia, the greater the danger during the narcosis. It is best to anesthetize the patient in a room free from noise, and do no talking, excepting to the patient, while inducing the narcosis; and the anesthetizer should invariably have someone within easy reach to aid him in case of emergency. There should be as little disturbance and lifting of the patient as possible after the anesthesia has begun, so as to avoid disturbing the anesthesia in its early stages. During the past two years I have followed the custom of William J. and Charles H. Mayo of Rochester, Minn., of having patients anesthetized in the operating room on the operating table.[27] I then have them under my own eye from the beginning of anesthesia, and there is no disturbance or loss of time due to changing from cart to table. It is seldom that quiet, almost noiseless breathing can not be maintained throughout a narcosis. The yielding of the jaw is a trustworthy indication of the approach of surgical narcosis. If the jaw is rightly managed the gag and the tongue forceps will very seldom be needed. When the forceps are used it is seldom necessary to lacerate the tongue or to nearly amputate it by pulling it constantly downward across the lower incisors. The administration of the anesthetic, whether ether or chloroform, should begin gradually.

There are two ways of avoiding overdosage, which are too often neglected: 1, expedition in getting the patient on the table and ready for the surgeon after narcosis is complete; 2, as rapid operating as is consistent with thoroughness and safety. In fewer words, avoid giving the anesthetic a moment longer than necessary.

Danger Signals.—There is no one signal that is an infallible early guide. The pupillary reflexes are the best single guide to impending danger. A rapidly dilating pupil means danger, and a fixed, dilated pupil means extreme danger. A contracted, immobile pupil usually indicates safe surgical anesthesia; a pupil oscillating between contraction and dilation, diminishing anesthesia. The pupil is sometimes modified by the nature of the operation, as by manipulation of extremely sensitive tissues, or by suddenly changing the patient's position. The color of the face, lips, ears, and nose should be constantly observed. An ashen hue of any of these parts should create apprehension. Blueness of the skin is generally due to asphyxiation, and is much less dangerous than abnormal paleness, which generally indicates gradual poisoning of the circulatory mechanism, including the center in the medulla. To emphasize these conditions, Wm. Mitchell Banks[28] speaks of the "blue" man and the "white" man. The latter is in great danger. A. P. Ohlmacher[29] maintains that in the condition of lowered vital resistance known as the lymphatic constitution there is a strong tendency to sudden death in anesthesia. The respiration and pulse should be watched in all cases with the greatest care, no matter what anesthetic is being administered. The reflex rigidity occasioned by manipulation of sensitive tissues often demands temporary withdrawal of the anesthetic, whereas the temptation is to "crowd" it. Likewise, great vigilance should be exercised by the administrator when the surgeon is severing large nerve trunks.

Respiration during anesthesia should, as a rule, be easy and quiet. Snoring or stertor suggest either partial obstruction or too much anesthetic. When the epiglottis drops back it is necessary to introduce the finger into the mouth and lift it away from the glottis. If these maneuvers fail, artificial respiration by the

29. Philadelphia Med. Jour., March 10, 1900.

Sylvester method should be instituted. If then no air enters the lungs, the trachea should be opened. If the heart becomes weak during the anesthesia, it is well to inject subcutaneously a cardiac stimulant, as nitroglycerin, digitalis, spartein, strychnin. If amyl nitrite be given, remember it is only the temporary vasomotor dilator action that is wanted. If pushed beyond this not easily determined limit it may cause cardiac paralysis. The head-down position, by determining more blood to the circulatory center, aids in strengthening a heart which has become gradually weak.

TREATMENT OF EMERGENCIES.

Methods of treating emergencies may be thus summarized:

1. Reflex excitation of respiration by external application—for example, cold or cautery to the epigastrium, ammonia vapor to the nostrils.

2. Reflex excitation of respiration by mechanical means—as rhythmic traction on the tongue (Laborde), or divulsion of the sphincter ani.

3. Artificial respiration. Tracheotomy (when other means fail).

4. Measures counteracting circulatory failure—like posture or rhythmic compression of the chest or abdomen.

5. Cardiac stimulants—as amyl nitrite, nitroglycerin, strychnin, atropin, spartein, aromatic spirits of ammonia.

6. Bleeding from a large vein to relieve the over-distended right heart (when other means fail).

In the majority of cases oxygen, either pure or atmospheric, is the best resuscitant; but in some instances well-selected drugs are beneficial.

It should be kept in mind that in the first and second classes the nerves must be sufficiently alive to convey stimuli.

VOMITING DURING AND AFTER ANESTHESIA.

Serious or persistent vomiting, either during or after anesthesia, can nearly always be prevented by right management of the patient and of the anesthesia. In the first place, the patient must be properly prepared for the administration, and an anesthetic selected which is suitable for the particular case in hand.

Postanesthetic vomiting can be reduced almost to insignificance, if the patient is properly prepared for the anesthesia; if the anesthetic be carefully selected and skilfully administered; if the patient be transferred from the operating room to bed without much jarring, and kept perfectly quiet and free from disturbance in bed; and, finally, by freeing the stomach of accumulated mucus or bile. During the past five years I have practiced gastric lavage, as suggested by I. P. Gunby of Sherman, Texas.[30] Physiologic saline solution may be used, and from one to two quarts is usually sufficient. A medium-sized or small soft rubber stomach tube is introduced, through the nose, as soon as administration of the anesthetic is suspended, and the stomach washed while the dressing is being applied. During the procedure the patient's body should be sufficiently inclined head downward to prevent fluid from entering the trachea. This procedure aids materially in reducing vomiting to insignificance.

Another method for the prevention or control of postanesthetic nausea, introduced by Mackenrodt, is the inhalation of vinegar. It is supposed to be equally efficacious after ether or chloroform. After trying it in several hundreds of cases, I have concluded that this method is of little value.

30. Medical News, Jan. 21, 1899.

DEDUCTIONS.

1. It is not justifiable to employ any one anesthetic exclusively. The safest anesthesia depends on: 1, the choice of the anesthetic best adapted to the case in hand; 2, the best technic of preparation, administration and general management; and, 3, a skilful anesthetizer.

2. The recent advance in our knowledge of local and neuroregional analgesia has materially narrowed the field of general anesthesia, but the local method can not supercede the latter.

3. Cases for anesthesia should be divided into three groups: 1, cases in which the indications for local anesthesia are absolute; 2, cases in which the indications for general anesthesia are absolute; and 3, doubtful cases. If in doubt, use the general anesthetic.

4. The mere fact that an operation can be performed under local anesthesia is not sufficient justification for its employment. As a rule, better work can be done under general narcosis, and, especially in septic cases, postoperative complications are less likely to occur after a skilfully conducted general anesthesia than after local.

5. Both ether and chloroform exert a destructive effect on the erythrocytes and reduce the amount of hemoglobin (chloroform having the greater destructive action), hence, in anemic patients at least, the blood should be examined before administering an anesthetic. When the percentage of hemoglobin is below 40 an anesthetic should not be given when it can be avoided. Even with a hemoglobin percentage of 50 the danger is great.

6. Chloroform tends to cause fatty degeneration of the heart, liver and kidneys, while ether has very little effect in this direction. On the kidneys the effect of ether properly administered is usually transient; that of chloroform is likely to be more serious and prolonged.

7. Ether is a respiratory depressant, and usually exerts its bad effects primarily on the respiratory system. Chloroform is a circulatory depressant, and usually exerts its bad effects primarily on the circulatory system.

8. Nitrous oxid is a true anesthetic, and can be employed for prolonged operations (where complete muscular relaxation is not essential) when administered with certain proportions of oxygen, either pure or atmospheric. Its use is satisfactory only in skilled hands.

9. Ethyl bromid and ethyl chlorid are convenient for primary anesthesia and for short operations. They are probably less dangerous than chloroform. Both are circulatory and respiratory depressants.

10. Chloroform can not be made as safe as ether by admixture with other drugs, although the danger in its administration may be somewhat reduced by this means.

11. As a rule, strychnin or other heart tonic is indicated in the debilitated or preliminary to chloroformization, and morphin and atropin preliminary to etherization. Oxygen and posture are the best resuscitants.

12. Ether produces less circulatory depression than chloroform. It causes dilation of the arterioles and increased capillary circulation, thereby insuring a good blood supply to the circulatory and respiratory centers and to the heart muscle; consequently these systems are in less immediate danger than with chloroform.

13. On account of the reduction of body heat by anesthetics, they should be administered in a warm room; and the patient should be protected from loss of heat by proper covering of the body, by keeping it dry so

far as practicable, and by application of artificial heat when necessary. The temperature of the operating room should not be above 85 F. In changing the patient from operating room to bed, beware of cold halls or drafts.

14. Compression of the phrenic nerve will, if properly managed, usually control retching and kindred symptoms occurring during narcosis.

15. Postanesthetic nausea is best prevented by preparation and after-treatment which favor physiologic tonus, with especial reference to the emunctories, and by gastric lavage at the termination of anesthesia. Troublesome vomiting is in most instances quite unnecessary, no matter which anesthetic has been given. Chloroform is likely to cause more persistent nausea and vomiting than ether.

16. Patients should be well fed with easily digested and non-bulky food to within a few hours preceding anesthetization, and should be allowed water to within 2 or 3 hours of it. This plan reduces shock, favors elimination of the anesthetic and other waste products without undue irritation of the emunctory organs, and the patient will not suffer much from thirst and nausea. For the same reasons water should be given as liberally as practicable after anesthesia.

17. The danger from hemorrhage is no greater with ether than with chloroform, if as great, since the bleeding which occurs from the effects of ether is primary and is more certainly provided against; while the circulatory depression and vasomotor constriction due to chloroform to a great extent prevent primary bleeding and lead indirectly to later hemorrhage.

18. The safety margin between sufficient chloroform for anesthesia and the lethal dose is much narrower than it is with ether.

19. Anesthetic mixtures are in general less safe than the "straight goods." It is impossible to know the relative proportions of the different components of a mixture that the patient actually inhales; and when accidents occur the anesthetizer is hampered in his treatment by not always knowing which constituent is causing the trouble.

20. Ether-oxygen narcosis is safer than ether alone, by the "closed" method, but the oxygen gas is superfluous in most cases where ether is properly administered.

21. The ethyl bromid-ether method is a time saver, but is not safe. Ethyl chlorid-ether is probably still less safe.

22. Morphin-ether-chloroform anesthesia is of positive advantage in operations about the face, where it is difficult to maintain surgical narcosis by the ordinary means. Souchon's special inhaler is a valuable adjunct in these circumstances.

23. As a rule successions of anesthetics should be avoided, with the exception of nitrous oxid-ether.

24. Ether given alone is especially dangerous in the presence of arteriosclerosis, and chloroform especially so in anemia and where there are degenerative changes in the vital organs.

25. Partial or "talking" anesthesia is best in some cases, but should be avoided in prolonged operations unless taken quietly and with apparent abolishment of pain sense.

26. Primary ether narcosis stands next to nitrous oxid for short operations.

27. Hypnotic anesthesia should be employed only exceptionally, if at all.

28. In a patient liable to recurrent insanity, anesthesia is dangerous, but not so in one already insane.

29. Paralysis following anesthesia is almost always a pressure paralysis and is preventable.

30. In myocardial disease all anesthetics are especially dangerous, while in purely valvular disease they usually create but little disturbance. Ether is the anesthetic of choice, and is safer for many major operations in these cases than local anesthesia. Asphyxiation should be especially avoided in administering an anesthetic in the presence of heart disease. The use of chloroform is entirely out of question in myocardial disease.

31. In the plethoric and the obese, especial care must be exercised in the selection and administration of anesthetics, the chief danger encountered being from respiratory disturbance (often due to turgescence and consequent swelling of the boundary parts of the upper air passages).

32. Ether is the best anesthetic in obstetric practice. Chloroform is more dangerous to both mother and child.

33. Rectal etherization is feasible, but too dangerous to be employed in a routine way in any class of cases.

34. Any anesthetic, but especially ether, should be given with the greatest caution in the presence of special susceptibility to acute bronchial affections. Great care should also be exercised in the presence of asthma, and chloroform is in some cases preferable to ether.

35. Patients with peritonitis require a dangerous degree of anesthesia to produce relaxation of the abdomen. The anesthetizer should be extremely careful about "crowding" the anesthetic to overcome the rigidity brought about by the manipulation of sensitive or inflamed tissues, since handling such tissues often causes a dangerous degree of shock.

36. The best type of inhaler, for both chloroform and ether, is one made on the principle of the Esmarch chloroform mask.

37. The tongue forceps and the gag are seldom required, and the latter often endangers life, as ordinarily used. The right management of the jaw during narcosis will nearly always render these instruments superfluous.

38. The anesthetizer should gain the confidence of the patient as to his carefulness and ability, so that the mind may be at rest on these points. Patients who greatly fear anesthesia are the ones liable to cause the anesthetizer the most trouble.

39. The patient should be kept as free as possible from noise and other disturbances during the induction of anesthesia.

40. "Crowding" an anesthetic is usually not justifiable, as it adds materially to the danger. The necessity for "crowding" is the chief objection to the use of the nitrous oxid-ether method as ordinarily carried out.

41. No time should be lost in getting the patient in the hands of the surgeon after narcosis is complete; and the surgeon should operate as rapidly as possible consistent with good work.

42. In administering an anesthetic the dose should be regulated by the effect. The elaborately constructed pseudo-scientific apparatus for accurately measuring the dose is dangerous, cumbrous and expensive.

43. When chloroform is used, administer it slowly, especially in the early stages of anesthesia. The amount of anesthetic needed for the average subject varies with climatic conditions.

44. The pupillary reflexes constitute the best guide to the presence or absence of surgical anesthesia, and the best danger signal. Touching the cornea with the finger to determine the presence or absence of surgical anesthesia is unwarranted. The anesthetizer should watch

carefully the pupils, pulse, respiration, and the color and condition of the skin, depending on no single symptom as a danger signal. The patient should be carefully watched from the beginning of the anesthesia until fully restored to consciousness.

45. When anesthetics are properly administered the patient seldom struggles. Noisy respiration during anesthesia should be the exception, as it generally means faulty management.

46. The minimum amount of anesthetic should be given which is consistent with the production and maintenance of the desired degree of anesthesia.

47. The weight of evidence is overwhelmingly in favor of ether rather than chloroform. There are very few contraindications to ether when it is properly managed.

48. Statistics do not sufficiently represent the dangers encountered, as the hair-breadth escapes far outnumber the deaths.

49. The skilful anesthetizer is never at a loss to know what to do in emergencies—and he does the necessary thing instantly. Most of the deaths occur in the hands of the relatively unskilled.

50. The greatest danger from chloroform is during the second stage of narcosis. Profound chloroform narcosis should not be induced within five minutes, nor should it often require more than ten minutes to produce it.

51. Chloroform is nearly or quite as dangerous in the vigorous as in the debilitated, because the vigorous circulation takes it up and distributes it rapidly. Often it is the concentration of chloroform in the system, rather than the amount, which kills.

52. In the treatment of anesthetic asphyxia, tracheotomy should be resorted to when other means fail.

53. In anemia of the medulla the patient should be placed in the head-down position. In sudden paralytic dilation of the right heart, as after several deep inhalations of chloroform, the heart should be rhythmically compressed by squeezing the chest; or the patient placed temporarily in the feet-down posture to empty the heart, artificial respiration being constantly maintained.

54. The safe anesthetic will probably never be found, as the production of unconsciousness has an element of danger associated with it. Nitrous oxid-oxygen anesthesia is the safest anesthesia known.

55. It is more the method employed and skill displayed in administering anesthetics than the particular anesthetic used that in most cases lead to favorable termination and rapid recovery from an operative procedure.

56. The surgeon is frequently more concerned about the anesthetizer's work than about his own, as in over half the cases the anesthetic is more dangerous than the operation. The surgeon can not do his best operating while devoting half his attention to the anesthetic.

57. When possible, anesthetics should be administered by those especially skilled in their use. The specialist in anesthesia is a necessity of the times, and in order to become a first-class anesthetist special aptitude is required.

58. The subject of surgical anesthesia should be taught as a special branch in medical colleges, and each senior student should have practical experience along this line, under the supervision of a skilled anesthetist.

59. If all physicians and surgeons could be made to realize the fact that chloroform is vastly more dangerous than ether, then chloroform would be discarded as a routine anesthetic and used only in exceptional cases.

Note.—At the meeting of the American Surgical Association, held in Washington, May 12-14, 1903, John C. Munro, Boston, reported a series of 500 surgical patients showing albumin and casts in the urine, without evidences of renal degeneration before anesthetization. Nearly all of these patients were anesthetized with ether, and in none of them was any noticeable renal damage inflicted. Most of these patients were of the poorer classes and entered the hospital poorly nourished and debilitated.

DISCUSSION.

Dr. James E. Moore, Minneapolis—I dissent from the last statement the gentleman made. I have been doing surgery for the past thirty years, and have done a lot of it during the past twenty years. I have used chloroform in 95 per cent. of all my operations, and I have never had a death, either at the time or subsequently, due to the anesthetic. The author says that when a patient dies from ether anesthesia it is usually due to faulty administration. That remark, gentlemen, applies eminently to chloroform. His third conclusion is worth discussion, if he had made no other remark during his whole paper. He says a competent anesthetizer is necessary. With a competent anesthetizer I have no fear of chloroform, save in cases where its use is contraindicated, and the longer I use it the more convinced I become of the truth of this principle. It is not the anesthetic that is dangerous so much as the unskilled anesthetizer.

Dr. A. J. Ochsner, Chicago—The statement made by Dr. Moore concerning the anesthetist who understands his business thoroughly is absolutely correct, but we must remember that more than one-half, and possibly more than three-fourths, of all the anesthetics are administered by anesthetists with very little experience, consequently, with the conditions as they exist, I believe that the last conclusion of the author will still stand. In my own practice I use chloroform to anesthetize the patient regularly and change to ether before the operation is begun, unless there is a distinct contraindication, and I do it because I have a competent anesthetist. I would not do so unless I had. So, taking the conditions as they should be, I believe that Dr. Moore's point would be perfectly right, but taking the conditions as they exist, I believe that the author's conclusion is absolutely correct. There is always a feeling of confidence in the operator, if his anesthetist is not experienced in giving ether, because the more he gives the better it is for the patient, while, if the same anesthetist should give too much chloroform it would be very bad for the patient. I would say that if either of these anesthetics give trouble to the patient, then that anesthetic should not be used again during the same operation. If chloroform be given and the patient shows any bad symptoms, the chloroform should be abandoned throughout the operation, because the second or third time that trouble comes it may be fatal. In the administration of chloroform one point to be borne in mind which very frequently is overlooked, is that when trouble comes it is important to get rid of as much of the chloroform as possible. In making artificial respiration for the purpose of resting the patient, as a rule, the first thing done is to lift the arms and fill the lungs, presumably with air, but as a matter of fact with the chloroform, which is in the upper part of the lungs, and therefore, instead of giving the patient air you give him a very large dose of chloroform on top of what he already has. Therefore, the first thing to do is to make a number of very rapid and complete compressions of the chest in order to force out as much of the chloroform as possible. Aside from artificial breathing, I believe there is absolutely no use in all the methods which have been recommended for the purpose of reviving patients who have gotten into a dangerous condition during the administration of an anesthetic. There are but very few minutes to do anything for the patient if there is real danger. The practice Dr. Mellish makes of preparing the patient is very good. By his taking a big dose of castor oil to get rid of the fecal matter he is placed in a much better condition to stand the anesthetic. Of course, if his kidneys are bad, or if he has a bad heart, these conditions should be looked after.

The element of confidence on the part of the patient is of the very greatest importance. If you have a person giving the anesthetic in whom the patient has confidence that patient is not likely to get into trouble. If the patient vomits after the operation, gastric lavage will give immediate relief in most cases.

DR. M. B. TINKER, Baltimore—Local anesthesia I feel should be so much more extensively used than is now done. Many surgeons do not appreciate how much can be done under local anesthesia. As an example, hernia operations can be done under cocain and with so little discomfort to the patient that they say in many instances that the pain is less than attempts made to reduce the hernia by taxis. I would not advocate local anesthesia in all cases by any means, but I am convinced that it does save a certain number of deaths from ether pneumonia, lung embolism, heart failure and other causes which I do not believe can be avoided if general anesthesia is employed. Several factors essential to success in the use of a local anesthetic: In the first place the patient should understand the advantages of operation under local anesthesia, and want it done in this manner. If he does not want the operation done in this manner he will object to the slightest pain and you will not be successful. Another point of great importance is the necessity for taking plenty of time; you can rush local anesthesia. You have to take care to infiltrate tissues well and take time for dissection. If you do not you will cause your patient much pain and he will complain so bitterly that you can not complete the operation. A good sized preliminary dose of morphin is also of great importance, say 1-6 of a grain one hour before the operation, another 1-6 at the beginning of the operation and still another 1-6 during the operation. A good moral anesthetist at the head of the table will be of great advantage in distracting the patient's attention from the slight pains.

DR. WILLIAM J. MAYO, Rochester, Minn.—We have for years preferred ether to chloroform, even though there may be just as many deaths from ether as from chloroform. When a fatal result does occur, the patient has a much better chance to bid good-bye to his friends than if he died from chloroform anesthesia. Dr. Ochsner brought out one very excellent point, that the first thing to do in trouble from chloroform anesthesia is to force all of the chloroform out of the lungs by compressing the lungs before forcing the patient to take an inspiration. The Souchon anesthetizer is a very valuable apparatus for operations on the throat and mouth.

There is a large tendency in this country to settle things in the laboratory. This can not be done. Now, take the question of hemoglobin, and the influence which it exerts on anesthesia; the amount of hemoglobin present is not usually so important a fact as is the cause of a loss of hemoglobin. I have often operated when the hemoglobin was as low as 25 per cent., due to hemorrhage, and I have never seen an accident following such an operation. But if you do an operation on a case in which from some malignant cause the hemoglobin is reduced to 40 per cent. or 50 per cent., and the oxygen-carrying power of the patient is decreased, you stand a chance to lose the case because with cachexia the blood is poor in oxygen-carrying power. We are exceedingly afraid of low hemoglobin in cancerous disease, but I would not hesitate to perform an operation with the hemoglobin as low as 25 per cent., provided the disease is due to blood loss resulting in anemia, and provided I can reach the cause of the loss of hemoglobin.

DR. JOHN E. SUMMERS, JR., Omaha—I want to call attention to the post-operative effects of anesthetics on the temperature curve. For some time I have been noticing that after prolonged operations under ether we would occasionally get a temperature curve. This used to be called "reaction," but now I have become convinced that it is due to the anesthetic. I have gotten so that I think I can recognize it, and am not alarmed.

Anybody who has lost a case on the table never forgets the anesthetic. I have had the misfortune to lose one case on the table from chloroform, and it does not make me feel any better to know that every surgeon in my vicinity has had the same experience. Death comes so suddenly that it does not give you an opportunity to protect yourself or your patient. Dr. Mayo has expressed it very nicely by saying that it does not even give the patient an opportunity to say good-bye to his physician or his friends. Recently a little child was brought into the hospital with a compound fracture of the leg. He was given chloroform and the fracture reduced. Just as he was coming out of the anesthetic he vomited and aspirated some potato into his trachea. I opened the trachea immediately, but the child died from asphyxiation. I think it is always better in emergency work, especially among children, to wash out the stomach prior to the administration of the anesthetic, and in our hospital where much emergency work is done, I have made this a standing order because we can not know whether the stomach is empty or full.

In the Johns Hopkins Hospital, I notice by their Bulletin, that Cushing has found by experiments with the tonometer that chloroform always reduces arterial pressure more than does ether. I think there is no doubt that we are more liable to have accidents happen if we use chloroform than if we administer ether.

DR. E. J. MELLISH, El Paso, Texas—Dr. Ochsner spoke about using chloroform in all cases when he has a competent anesthetizer. It can be used more safely with a competent anesthetizer, but I have found from experience that no matter how chloroform is used it is more dangerous than ether. Dr. Moore's favorable experience with chloroform is doubtless due to skilful management of the anesthesias. Within a period of eight years I saw four deaths on the table from anesthetics, three from chloroform and one from ether. The patient who died from ether was extremely apprehensive before the anesthesia—lacked the necessary confidence in the anesthetizer. When this confidence is absent the danger is greatly increased. I have had at my disposal the records of 6,000 anesthesias at a Chicago hospital. The first three thousand anesthetics were given under the supervision of skilled anesthetizers. The last three thousand were given by those much less skilled in the administration of anesthetics. There were three deaths in this series, all occurring in the second three thousand cases. When chloroform is used, dangerous symptoms are likely to develop much more rapidly than after ether administration, and in the latter condition you have a much better chance to resuscitate your patient.

Another thing is, that chloroform, being heavy, is eliminated very slowly, and it has been detected in the sputa two or three days after the anesthesia. This means that the patient is continuously more or less poisoned during this time. Ether is eliminated much more rapidly.

TWO CASES OF PARATYPHOID INFECTION; ONE CAUSED BY AN ABERRANT ORGANISM.

G. BERTNARD SMITH, S.B.
(FROM THE BACTERIOLOGICAL LABORATORY, UNIVERSITY OF CHICAGO.)
CHICAGO.

Cases of paratyphoid fever, both sporadic and epidemic,[1] have been reported so frequently of late that perhaps some special reason should be given for calling attention to any more isolated cases. In the present instance the author believes that the bacteriologic findings are of sufficient interest to warrant a brief presentation:

CASE 1.—The patient, a man aged 58 years, entered the Presbyterian Hospital, Oct. 22, 1902. His temperature by mouth was 102.2, and he complained of frontal headache and severe abdominal pain. The abdomen was tender everywhere, but the liver and spleen were not palpable and no rose spots were visible. November 1 the patient had two hemorrhages from the bowels. The first was slight and only a small amount of blood was cast out. About three pints of liquid blood containing some clots were discharged with the second hemor-

1. Conradi and v. Drigalski: Zeit. f. Hyg., 1903, xlii, 141.

rhage. The abdominal distress and headache continued through the first week of November, and during this time the patient was very weak and restless and at times slightly delirious. Beginning with the second week of November he began to show definite signs of improvement, and from this time his progress was uninterrupted and he was discharged November 21.

No rose spots were found at any time. The Widal test for typhoid was persistently negative throughout the course of the disease, even in dilutions as low as 1 to 10.

Five cubic centimeters of blood were drawn from one of the large veins of the arm, using the usual surgical precautions for asepsis. About 3 c.c. of this blood were put into five flasks each containing 150 c.c. of sugar-free bouillon and within twenty-four hours the organism to be described was obtained in pure culture.

This organism resembles the typhoid bacillus in morphology. It shows no capsule; it is not sporogenic. It stains somewhat unevenly with anilin dyes and is readily decolorized by Gram's method. It is motile, but is more sluggish than *B. typhosus*.

CULTURAL CHARACTERISTICS.[2]

Bouillon.—A uniform turbidity is shown in twenty-four hours. No scum forms even when growth continues for several days.

Agar.—A heavy white growth appears in twenty-four hours. This is moist with a raised margin and a smooth homogeneous surface. The growth is largely limited to the line of inoculation.

Litmus Milk.—No change is noticeable during the first forty-eight hours, but after the second day the reaction soon becomes strongly acid. No precipitation of casein occurs. At the end of several weeks the medium presents a deep blue color.

Gelatin.—No liquefaction occurs.

Neutral-red Agar.[3]—Both stab and shake cultures were used. A few gas bubbles formed, but no change occurred in the color of the media, even after several weeks.

Carbohydrates.—Glucose, saccharose, levulose, lactose, mannite, galactose and dextrin were tested in the fermentation tube. One per cent. of the carbohydrate was added to ordinary nutrient broth after removing the muscle sugar. Care was observed in every case to prevent overheating the sugar broths, and all that became darkened in heating were discarded. Gas production occurred only in the glucose broth.

REPORT OF A SECOND CASE.

A second case came to the writer's attention at the time the organism just described was being studied. This case was a private patient of Dr. James W. Walker and the organism was isolated by Dr. Harris of the College of Physicians and Surgeons, Chicago, and given to me for further study. This organism resembles very closely the bacillus isolated from Case 1 in its morphology and growths in bouillon, agar and gelatin.

Litmus Milk.—A slight acidity is noticed within the first twenty-four hours, but this is lost during the second or third day and the color again becomes neutral. After several weeks the medium assumes the same deep blue color described under Case 1.

Neutral-red Agar.—Gas bubbles are formed within twenty-four hours in both stab and shake cultures. The color is rapidly changing during this time so that only in the lower one-fifth of the medium does the color still persist. It is almost entirely reduced to a light yellow by the end of the fourth day. After the first week the color gradually returns until the original appearance is again given. This return of color seems to occur from above downward instead of from below upward, as described by Buxton.

Carbohydrates.—This organism was grown in saccharose, glucose, mannite, levulose, lactose and dextrin media, using 1 per cent. in bouillon as before. Gas was formed in each case except in the broth containing saccharose and lactose. The fermentation tests with this organism seemed to follow so closely the results described by Buxton[4] with his paratyphoid bacillus and closely allied forms that a comparative study was made in the different carbohydrates with the two forms here described and Buxton's organism. The gas formed was only roughly analyzed by the use of 2 per cent. NaOH.

PARACOLON BACILLUS FROM BUXTON'S CASE 7.

* No fermentation was obtained with saccharose, mannite, levulose, lactose and dextrin.

A comparison of the tables showing the carbohydrate tests indicates a close relationship between Buxton's paratyphoid bacillus and the organism[5] isolated from Case 2. This is also shown by a comparison of the growths in litmus milk and neutral-red agar. In order to study still further this similarity a comparison was made of the agglutinative characteristics of Buxton's form and the two organisms here described.

MICROSCOPIC AGGLUTINATION TESTS.

No dilutions were made above 1 to 100. Buxton's paracolon was tested with serum from Case 2 and agglutination was shown in dilutions as high as 1 to 50. Serum from Case 2 was tested with Bacillus 1, and agglutination occurred in all dilutions as high as 1 to 50. Above this, dilutions as high as 1 to 100 gave almost complete agglutination, but I was unable to decide at any time that all motility was positively lost. Serum from Case 1, and also from Case 2, was tested with typhoid and hog cholera bacilli and *B. enteritidis* with negative results in every case even in dilutions as low as 1 to 10.

MACROSCOPIC AGGLUTINATION TESTS.

Small hemolysis test tubes were used in which the bacilli, in definite quantities, were added to a serum of the desired dilution, and after three hours' incubation the results were noted with the naked eye. The agglutination was considered positive only when complete

2. Except where stated otherwise all media were prepared according to the "Proceedings Recommended for the Study of Bacteria." Reports and papers of the American Public Health Association, 1898, xxviii, p. 60.

3. Neutral red agar was prepared by adding to neutral agar 0.5 per cent. dextrose and 1 per cent. of a 0.5 per cent. aqueous solution of neutral red (Grübler's).

4. Buxton: Jour. Med. Research, 1902, viii, 201.

5. The forms isolated from Cases 1 and 2 will hereafter be referred to as Bacillus 1 and Bacillus 2 respectively.

precipitation had occurred, leaving the liquid clear. Serum was obtained from four rabbits. Of these, one was immunized with Buxton's paratyphoid bacillus, the inoculations being continued until rapid agglutination was given at 1 to 2,000. A second rabbit was immunized with a typhoid organism.[6] The third rabbit was inoculated with the bacillus of hog cholera[7] until complete agglutination was given at 1 to 1,000. The fourth rabbit was inoculated with the *B. enteritidis*.[8] The degree of agglutinative power reached in the serum of this rabbit was much lower than in any of the others, as the highest dilution giving positive results was 1 to 400.

Serum from the rabbit immunized with Buxton's paratyphoid bacillus gave negative results in dilutions of 1 to 10 with the bacilli of typhoid and hog cholera and with *B. enteritidis*.

Sera from the rabbits that had been inoculated with the organisms of typhoid, hog cholera and with *B. enteritidis* gave negative results at all dilutions with Buxton's form and with both Bacillus 1 and Bacillus 2. Bacillus 1, when added to Buxton's serum, was agglutinated at 1 to 100. Above this the precipitation was never found to be complete. Bacillus 2 was completely precipitated by the Buxton serum at all dilutions as high as 1 to 2,000. No dilutions were tried above this. Using the sign + to indicate complete agglutination, these results may be tabulated as follows:

	Bacillus 1.	Bacillus 2.	Buxton's form.
Buxton serum	+100	+2000	+2000
Typhoid serum	— 10	— 10	— 10
Hog-cholera serum	— 10	— 10	— 10
Enteritidis serum	— 10	— 10	— 10

To summarize, Bacillus 2 must be regarded as an organism which possesses the general characteristics of the paracolons, and, from its growth in litmus milk and neutral-red agar, together with the fermentation and agglutination tests, possesses a close relationship to Buxton's form. I have not made comparisons with other members of the paratyphoid group, but from Buxton's comparative study Bacillus 2 would seem to belong to the subgroup which comprises the organism isolated by Gwyn,[9] two forms described by Johnston,[10] Hewlett's form,[11] the bacillus Müller of Schottmüller,[12] Buxton's paracolon[13] and possibly Cushing's[14] Bacillus O.

Bacillus 1, while conforming to the general tests for paratyphoid bacilli, seems to occupy rather an independent position. The clinical history of this case is specially interesting because it shows the occurrence of two hemorrhages from the bowel. In the eighty-four cases of paratyphoid infection that have been reported, but four cases with hemorrhage have occurred. One was the case reported by Gwyn. Another, reported by Strong[15] showed a complication from malarial infection. The third case was reported by Hume[16] and the fourth was one of an epidemic of fourteen cases reported by De Feyfer and Kayser.[17]

In morphology, Bacillus 1 shows no important points of difference from the rest of the paratyphoid bacilli which have been described, but in its special cultural characteristics it presents very marked individuality. It develops a strongly acid reaction in litmus milk, which does not, however, cause a coagulation of the casein and which changes to the typical alkaline state, although very slowly. No reduction in the color of the neutral-red agar occurs, which would seem to point toward a relationship with the typhoid bacillus.

The absence of fermentation, except in the glucose media, shows a particularly wide departure from the common type of paratyphoid organism studied by Buxton.

I am indebted to Dr. E. O. Jordan for many valuable suggestions and criticisms during the progress of this work, and to Dr. B. W. Sippy, who was the attending physician to the first case I have reported, for favors received at the hospital.

6. This form was Typhoid 6 of Theobald Smith, which was originally obtained from the spleen of a typhoid patient. This serum agglutinated the typhoid bacillus in dilution of 1 to 25,000.

7. This organism is one obtained from V. A. Moore of the New York State Veterinary College, Cornell University.

8. This organism is from the stock cultures of the university laboratory, and possesses the typical cultural characteristics of *B. enteritidis*. The source is unknown.

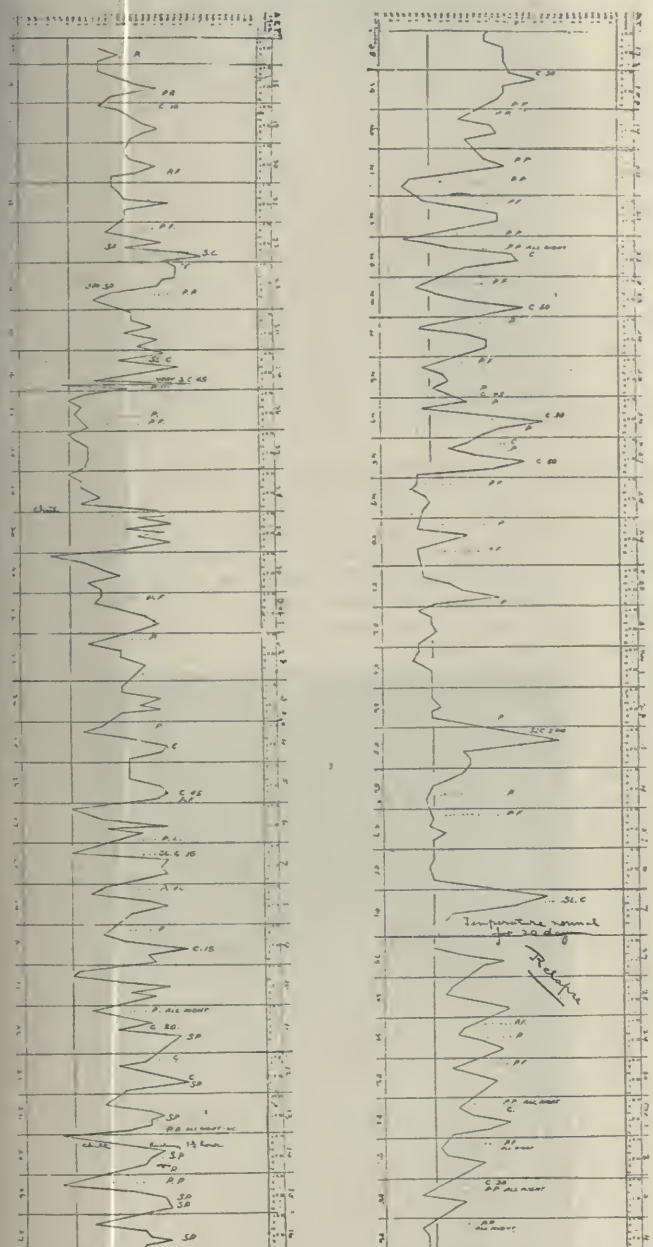
Clinical Reports.

A CASE OF PARATYPHOID.

JAMES W. WALKER, M.D.
Adjunct Professor of Medicine, College of Physicians and Surgeons.
CHICAGO.

Until the symptomatology of the various forms of paratyphoid has been tabulated more completely than at present, apology for publishing clinical cases in detail should be superfluous. For the working out of the bacteriology and, therefore, for the establishment of the diagnosis, I am indebted to Mr. G. Bertnard Smith, who publishes his report separately in this number of THE JOURNAL, and to Dr. Fred G. Harris, pathologist of Cook County Hospital, who began the culture.



Dr. H. M. R.; aged 30; Jewish; family history negative. Eleven years ago was ill for ten days with what was said to be typhoid, but this is doubtful. Has not been out of Chicago for years. Present illness began about Sept. 10, 1902, with malaise, chilly sensations, headache, anorexia, free perspiration and slight temperature, with which symptoms patient went about his professional duties for a week, and on September 17 went to bed with what he and I presumed was ordinary typhoid fever. Pulse was then 80; physical examination negative, and it may be stated here to dispose of the matter, that at no time was the spleen palpable, there were never any rose spots, no tympanites, no diarrhea, no abdominal tenderness, in short, no abdominal symptoms nor signs. There was never any cough, nor was the tongue ever dry; patient was never unconscious, though there was some stupor during the first days in bed. From the beginning the chills (see temperature chart), perspiration and fever were the dominant symptoms, and led to a repeated search for the *Plasmodium malariæ*, which was fruitless.

September 22 there was nausea and vomiting. September 23, very restless and uncomfortable. Second heart tone duplicated, pulse 130, dyspnea evident when talking, no râles nor cough, complained of diffuse pain throughout the chest. September 24, numbness of both little fingers, severe chills, albumin in the urine.

September 25, (1) The repeated severe chills, with absence of the plasmodium, and despite the liberal use of quinin; (2) the drenching sweats, (3) the diffuse chest pain, (4) the increasing dyspnea, (5) the absence of the Widal and Ehrlich reactions, (6) absence of all abdominal symptoms and signs, (7) the very irregular temperature, and (8) the general evidence of profound toxemia in the absence of a discoverable local lesion, strongly inclined me to think the case one of acute miliary tuberculosis.

17. De Feyfer and Kayser: Münch. med. Woch., 1902, xlix, 1692.

Dr. A. R. Edwards consulted with me and saw the patient when at his worst. He thought the chances between tuberculosis and an atypical typhoid were about even, with a slight leaning toward the latter. Within five hours the clinical picture was much changed, and with it my opinion. Patient became cheerful and brighter and the dyspnea was diminished. His temperature had fallen seven degrees in one hour, and it then remained below a hundred for nearly three days. The change was almost in the nature of a crisis. September 28, pain in the left groin developed and the following day a femoral thrombosis was evident on palpation.

Clinical chart of Dr. Walker's patient. Explanation of lettering: P. P., Perspired profusely. P. F., Perspired freely. P. V. L., Perspired very little. SL. P., Slight perspiration. SP., Sponged. V., Vomited. C., Chill. SL. C., Slight chill. S. C., Severe chill. The figures in connection with the chills indicate the duration in minutes, unless otherwise specified.

September 29 Dr. F. G. Harris inoculated five flasks of bouillon with blood drawn from a vein. It is from this culture that the findings reported by Mr. G. B. Smith are derived. Urine, specific gravity 1022, trace of albumin, peptone present, few hyaline casts. Pulse ranged about 110, except at time of chills, when it went to 130 or 140. October 15, no new developments. Phlebitis now hardly noticeable; feels comfortable, except when temperature rises; sleeps better. November 7, feels strong and free from pain. November 12, walked a little.

During the relapse, beginning November 27 and lasting one week (see chart), the only important symptoms were again the chilliness, perspiration and fever. He eventually made a complete recovery. Of the cardinal symptoms it may be added that the chills were of the severity of malarial chills, and the sweats so profuse that his nightgown had to be changed from three to seven times in a night. The variability of the fever is indicated by the chart. At different times during the course of the illness the blood was examined for the Widal reaction, independently, by Drs. Hektoen, W. A. Evans, F. G. Harris and G. B. Smith, with negative results.

SERRATUS PARALYSIS.

RICHARD LIGHTBURN SUTTON, M.D.
Assistant Surgeon, United States Navy.
WASHINGTON, D. C.

Owing to the comparative rarity of this particular type of peripheral palsy I report the following cases which recently came under my observation in the service of Dr. H. M. Thomas, in the Johns Hopkins Hospital Dispensary.

CASE 1 (Neurologic, No. 14,722).—An American woman, aged 32, married, and a housewife by occupation.

Family History.—Her family history is unimportant; her father, who had always enjoyed excellent health, died at an advanced age, and her mother is still living. There is no suspicion of inherited constitutional disease, and none of her immediate relatives has ever suffered from paralysis.

Previous History.—She had the usual diseases of childhood, pneumonia at 18 and typhoid fever at 20. There is no evidence of her ever having had venereal disease and she is not addicted to the use of intoxicants. She has been married four years, has a healthy child 3 years of age, and there has been one miscarriage, thirteen months ago. Her surroundings are good, and she has no hard or difficult duties to perform.

Two years ago she suffered from a peculiar numb, prickling sensation in the forearms and hands which came on suddenly and was not accompanied by local coldness, tenderness or edema. No weakness nor motor disturbance of the parts followed, although there was some stiffness of the phalangeal joints. The attack lasted eight days. She has since been well up to within two months previous to her admission to the dispensary, except for a slight, painful swelling of the left ankle one year later.

Present Trouble.—On May 5, 1903, while in her usual health and without any known cause, she experienced, immediately after taking a hot bath, severe pain in both shoulders, radiating down the arms. The pain was very intense, but gradually subsided in the course of three weeks. It was associated with some swelling of the hands, but the joints seem not to have been affected. After the subsidence of the pain she noticed a slight drooping of the right shoulder, with inability to manage the joint. She was unable to lift her hand to her head, although she could raise a bucket, or other heavy object, from the floor. A physician told her she was suffering "from a dislocation of the shoulder, due to rheumatic contraction of the muscles," and after two months' treatment it was with this complaint that she came to the dispensary.

Examination.—On admission the patient was seen to be a small, well-nourished, intelligent woman. Her color was good, teeth sound and well shaped, no blue line on gums, and the general physical examination was negative. There was no abnormality discovered in the functions of any of the cranial nerves. The movements of the head and neck were perfect. With the patient standing erect, when the trunk was examined posteriorly, there was some lateral curvature of the spine, the convexity being to the right.

At rest, with arms at side, the inferior angle of right scapula was a trifle more prominent than that of the left. When the patient endeavored to extend the arm anteriorly a marked deformity developed. The scapula rotated on its vertical axis, its inner border leaving the chest wall, giving the

typical picture of "wing scapula." This became more pronounced when the patient made an effort to depress the arm against resistance. She was unable to raise her hand above her head, nor could she abduct the arms laterally at more than a right angle. All the movements appeared to be somewhat impaired, although there was no paralysis of any of the muscles other than the serratus. The deltoid seemed a trifle flabby, but the muscles moving the elbow, wrist and smaller joints were apparently normal. The left arm and hand were unaffected. There was no sensory disturbance discovered.

Electrical examination showed a normal response to all muscles except the serratus, and we were unable to get a satisfactory contraction from it on either side, although several efforts were made with both the galvanic and faradic currents. The muscles of the trunk and legs were not affected.

Diagnosis.—It was evident that this patient was suffering from a paralysis of the serratus magnus muscle, due, in all probability, to a neuritis of the brachial plexus which had injured the trunk of the posterior thoracic nerve.

Treatment.—She was placed on tonic treatment, in the form of tincture of nux vomica, m. xx, t. i. d., and galvanism

Fig 1.—Case 2. Displacement of the right scapula when the arm was held horizontally in front.

applied to the brachial plexus and the affected muscles twice weekly. We were not able to secure a photograph at this time, but her condition is accurately depicted by the first picture of the accompanying case.

Course.—After the treatment had been continued for three or four weeks marked improvement was evidenced and an examination on September 8 showed almost complete restoration of function. The patient herself experienced no discomfort. She could raise the arm above her head or extend it laterally and the scapula showed no tendency to leave its normal position. If, however, she was given a heavy book and told to raise it upward the full length of her arm, then lower it slowly, the vertebral border of the scapula receded from the chest wall and the entire bone rotated slightly, showing that the muscle was still weak.

CASE 2.—(Neurologic, No. 10,407.) A white man, aged 38, a street-car conductor, first came to the dispensary Oct. 23, 1899.

Family History.—Negative, none of his immediate relatives, so far as he knows, having ever suffered from nervous or mental disease.

Previous History.—He has always enjoyed excellent health, does not remember having had the diseases of childhood, and denies venereal disease. Owing to the character of his work he is subjected to considerable exposure during bad weather.

Fig. 2.—Case 2. Displacement of the right scapula when the arm was held above and slightly in front of the head.

Present Trouble.—Five months ago he experienced a severe attack of pain in right shoulder accompanied by a swelling of the hand on that side. This came on without appreciable cause and persisted for three weeks. At the end of that time the edema had disappeared, but a dull, aching pain remained and he noticed impaired movement of the shoulder. It was for this condition that he came under treatment.

Fig. 3.—Case 2. Displacement of inferior angle of right scapula when the arm was held at the side of the trunk.

Examination.—The patient, on admission, was found to be a hardy-looking, rather muscular man of medium size, with face and hands showing evidence of exposure to sun. Teeth

fairly good, no blue lines on gums, functions of all the cranial nerves normal; the general physical examination was negative.

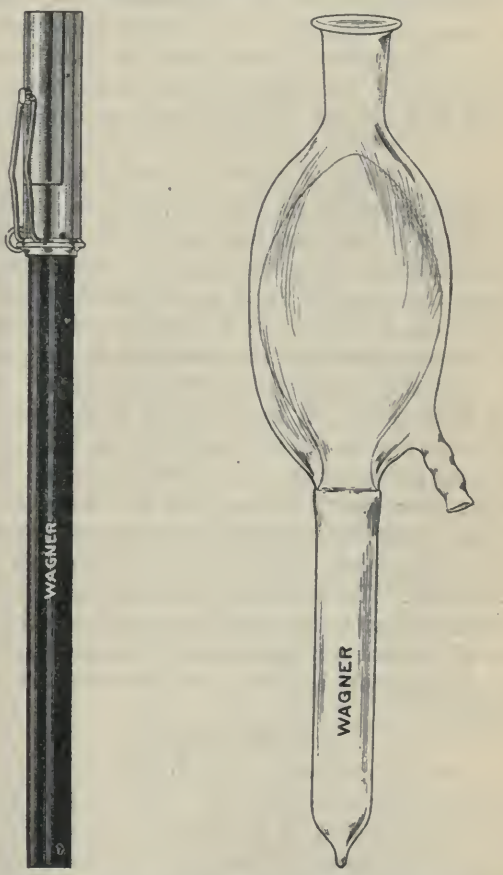
With the patient standing upright, arms at sides, the inferior angle of the right scapula was about 6 cm. higher than that of the left, and protruded backward from the posterior thoracic wall, a trifle farther than its fellow of the opposite side. There was marked impairment in the use of the muscles of the entire shoulder, because of inability to control or fix the scapula. When the hand was raised above the head by a second person the patient complained of pain in the region of the scapula, extending out toward the arm. The accompanying photographs give an excellent representation of the attitude assumed by the shoulder blade when the arm was placed in various positions. There was considerable atrophy of the right deltoid and both biceps and pectoral muscles were soft and flabby on that side.

Electrical examination showed a lack of faradic irritability only in the serratus and the lower portion of the trapezius on the right side, with a sluggish but not delayed reaction to the galvanic current in these muscles. The response was normal in all of the others.

Treatment.—The patient was given no internal treatment, but the right brachial plexus, posterior thoracic nerve and the affected muscles received galvanism twice each week for a considerable period of time. March 19, 1900, he was able to raise his hand above his head. The scapula still projected slightly when the limb was elevated.

Course.—He returned to work in August, 1900, but the constant and oftentimes violent movement brought on a relapse, and he was compelled to give up his position again. The current was applied regularly, however, and the improvement, while slow, was continued. In May of the following year (1901) recovery was complete, and he has not lost a day on account of illness since that time. A recent examination shows the parts to be normal in every way, and the electrical tests gave practically the same results on the two sides.

Comments.—Cases of serratus paralysis, although well recognized, are of uncommon occurrence. Among 14,956 cases registered in the neurologic department of the Johns Hopkins Hospital there are but these two uncomplicated conditions of this character. In each the etiologic factor was a neuritis of the brachial plexus, affecting the nerve supply of the serratus secondarily. The primary cause in Case 2 was, in all probability, exposure, coupled with overexertion of the parts comprising the shoulder girdle. The practical points illustrated by these two cases are: 1. The relative infrequency with which the condition is encountered. 2. The intimate relationship its etiology bears to inflammation of the nerve trunks composing the brachial plexus. 3. The liability to unilateral involvement of the right side. 4. The favorableness of the prognosis in cases where trauma is not a factor in the causation. 5. The importance of early and continued treatment by galvanism.



New Instrument.

THE HUGHES IONIZER.

R. V. WAGNER, M.D.
CHICAGO.

Electricity is generally conceded to be a mode of molecular motion, and the higher the voltage or tension of the current becomes, the higher the mode of motion. When electricity is conducted through a substance it must impart a mode of motion to its molecular structures, and if this mode of motion is violent enough it disassociates the molecular structures and breaks them up. Very high voltage or high tension currents conducted through the air decompose the elements of the air, producing ozone in large quantities; it is on this principle that ozone generators have been commonly constructed. But the highest tension currents do not impart as high a mode of motion to the molecular structures of the normal air as to those of rarified air; as the molecular structures of rarified air in a vacuum tube may be made to move at a much higher rate than is obtainable in any other way, the inductive energy arising from vacuum tubes impart a correspondingly higher mode of motion to the structures of the air surrounding them, producing more perfect decomposition.

It is on this principle that this new instrument has been constructed. A vacuum tube, excited by a high frequency, high tension current, is enclosed in a chamber through which air may be passed and the air acted on by the excited vacuum tube is much more finely broken up (breaking the molecular structures into atoms and the atoms into ions) than when the high-tension current is conducted through the air directly. One great disadvantage in the use of decomposed air is that the decomposed nitrogen produces effects on the tissues that are not desired, but in this instruument the air passing through the chamber may be made to carry remedies of an alkaline character so as to neutralize the acid effects produced by the decomposed nitrogen. If the ionizer be used in

combination with a nebulizer, the remedies held in suspension by the air acted on will be more finely broken up and decomposed than any nebulizer or atomizer is capable of doing, and in the treatment of nose, throat and lung troubles will be more effective by reason of the increased degree of penetration.

308 Dearborn St.

Accuracy in Therapeutics.—Medicine is a progressive art, and is becoming more scientific. Causes of symptoms and diseases are now known, and the attempts made at their eradication is a chief principle in treatment. Manual or mechanical aids are being used with increasing frequency and satisfaction. The local application of drugs is used much more frequently, instead of soaking the whole body to get the effect on some special part. Instead of huge doses of crude drugs, the alkaloids or active principles are being used, so that one can now medicate with as much skill and as definitely as he can use the knife, stopping short at the physiologic effect or increasing or decreasing the effect as he wills.—*Iowa Medical Journal.*

Special Article.

THE TYPHOID EPIDEMIC AT BUTLER, PENNSYLVANIA.

(From Our Special Commissioner.)

The newspaper reports of the typhoid epidemic at Butler, Pa., have not been exaggerated. Butler is a thriving little city of about 16,000 inhabitants, most attractively situated in a hilly country in western Pennsylvania, about forty miles northwest of Pittsburg. It is primarily an oil town, and as such has been considered particularly prosperous. The manufacture of plate-glass under local management is one of the leading industries. In the spring of 1902 the Standard Steel Car Company opened extensive works at Butler and these were in operation until a few months ago, when they were closed on account of the depression in the steel market. It is said that there were no "poor people" in the town until the advent of the steel works, which brought in a number of Hungarians and other foreigners.

PREVIOUS TYPHOID IN BUTLER.

Typhoid fever has not been unknown in Butler in the past, although the town has never before experienced a serious epidemic. It is said that there were seven deaths reported from typhoid fever in the month of November, 1902, which, if true, is a fact that the authorities should take into consideration in dealing with the present situation. It seems probable, however, that many of the typhoid fever deaths in Butler prior to the present outbreak were due to the proximity of the town of Pittsburg, long known as the hotbed of the disease. The close business relations of Butler with the latter city afford perhaps a sufficient explanation for the previous occurrence of occasional, indeed of rather frequent, cases in Butler itself. The records of cases and deaths, however, in accordance with the usual practice of small cities and towns in this country, have been so loosely kept that no exact information has been, or probably ever will be, obtainable.

PRESENT EPIDEMIC.

The present outbreak became first apparent early in November of the current year. On Sunday, November 8, the Butler Board of Health held an all-day session and as a result issued an address to the people of Butler advising them to boil all water used for domestic purposes. This prompt action seems to have been taken at the very beginning of the outbreak. After this date items to the effect that such-and-such a resident of Butler was ill with "the fever" appeared frequently in the local papers. It was not until about a week later, however, that any large measure of alarm began to be felt or expressed. On November 28 the gravity of the situation was manifest and the Pennsylvania State Board of Health was appealed to for aid and advice. Up to noon Saturday, December 5, a total of 1,180 cases had been recorded, and it is known that many more unreported cases actually exist within the city. Up to Saturday night 37 deaths had occurred. It is stated by those most familiar with the situation that over 60 per cent. of the cases have not yet passed the critical stage and it is feared that many more deaths will take place. Seventeen deaths have occurred within the last four days for which record is at hand. There is no doubt that the town is terribly stricken. Two, three or even more cases in the same family are not at all uncommon. The writer talked with one citizen who had had eight cases in his own family.

Even at this stage enough is known about the proportions of the Butler epidemic to establish it as one of the most appalling visitations from typhoid fever from which an American community has ever suffered. The disastrous outbreak at Ithaca last spring in a population of about the same size did not reach quite such gigantic proportions, and although the classical epidemic at Plymouth, Pa., in 1884 was probably more severe in proportion to the population of the town, there were in that case even fewer actual cases than at Butler.

SOURCE OF OUTBREAK.

The large number of persons attacked at Butler is in itself sufficient to cast suspicion on the water supply, and this fact conspired with other circumstances to render most plausible the hypothesis of a water-born origin. This suspicion became almost a certainty when the peculiar distribution of the typhoid fever cases became known. It transpired that the part of Butler lying south of the Baltimore and Ohio Railway tracks, and known locally as Springdale, was almost entirely exempt from infection. This district forms topographically and socially part of the town of Butler, and apparently differs only in the fact that it is not provided with city water, but obtains its supply from a number of artesian wells. In this part of the town, with a population of about 2,500, it is stated on high authority that but two cases have developed, one of these being a child who attended school in Butler, the other being a laborer employed in Butler. This remarkable topographical incidence pointed directly to the water supply as the source of the calamity, and further circumstantial evidence to the same effect is not lacking. No suspicious circumstances have been brought to light in the investigation of the milk supply and other theoretically possible sources, while the facts now to be set forth concerning the water supply are of a most significant and damaging character.

CHARACTER OF THE CITY WATER SUPPLY.

The water supply of Butler, which is controlled by a private water company (The Butler Water Co.), has been since 1878 obtained from Connoquenessing Creek and its feeders. The flow of this small stream is at certain times of the year inadequate to the needs of the growing town, and in order to furnish a constant supply the waters of the stream were impounded by a dam at Boydstown, some nine miles above Butler. This in turn did not furnish the required amount of water, and a second dam has been recently constructed on Thorn Run, about four miles above the town. The water seems to have been clarified for some time past by means of a small mechanical filter at the pumping station, a mile and a half above the town on Connoquenessing Creek, and two miles and a half from Thorn Run dam.

INFECTION OF THE WATER SUPPLY.

On August 28, the Boydstown dam was carried out in a flood, and the water company was obliged to use water

from the partly finished Thorn Run reservoir. Water was also pumped directly from the creek at the pumping station, and so scanty was the available supply that it is said that at times practically all the water in the creek was used. In the latter part of October, owing to an accident to some of the machinery at the pumping station, the mechanical filter was temporarily thrown out of use, and it was during this period that the maximum infection undoubtedly occurred.

Unfortunately, throughout the summer and early fall, opportunities for the infection of the Connoquenessing watershed appear to have been only too numerous. A number of cases of the disease existed on the watershed during this period and investigation has shown that there was ample opportunity for the uncared-for dejecta to enter the water of various small runs and tributary streams. At one house not far from the Thorn Run dam, a case of typhoid fever was brought to the family in the latter part of July and was followed by three others in the same household. At another house, on Sullivan's Run, even nearer to the pumping station, two cases of typhoid fever occurred, and it is considered probable that the infectious material from these two cases had a large share in infecting the water of the creek. Health officials who have thoroughly investigated the conditions report that for years cases of typhoid fever have been occurring at various points on the Connoquenessing watershed, and it apparently required simply a series of accidents to precipitate the present catastrophe. The situation is so discouragingly familiar as hardly to need repetition. The infectious materials discharged from the bodies of typhoid fever patients were thrown out on a steep, rocky hillside, or placed in loosely constructed out-houses, where the first heavy rain could wash countless millions of pathogenic bacilli into the water supply of an innocent community.

REMEDIAL MEASURES.

As soon as the existence of the epidemic became known the citizens were warned of the danger of using unboiled water for drinking and other household purposes. Hardly too much can be said in praise of the early recognition of danger by the local board of health and the prompt measures taken to prevent the spread of the outbreak. The Pennsylvania State Board of Health, likewise, responded at once to the call for assistance and seems to have acted with great promptness and efficiency. The sum of $2,000 was at once appropriated from the emergency fund at the disposal of the state board, local headquarters were established, the free distribution of disinfectants begun, the thorough inspection of the watersheds set on foot, and an effective system of house control established. A skilled veterinarian was also sent to Butler by the state authorities, and rigorous supervision of the milk supply is being exercised under his direction. The possible infection of utensils used in the distribution of milk is also being guarded against. The conditions governing the water supply are being improved as rapidly as possible. The mechanical filter is now thought to be in good working order, and an experienced water analyst from the Massachusetts Institute of Technology has been recently brought to Butler and placed in charge of the daily tests that are being made. The results of these tests are said to be very satisfactory.

RELIEF WORK.

When it became apparent to the outside world that the local resources were too seriously crippled to cope with the situation, help poured in on the town from all sides. In Philadelphia a large relief fund was subscribed and a number of physicians and nurses were soon on the ground. A temporary hospital has been established in one of the hotel buildings in Butler under the direction of the Philadelphia contingent, headed by Dr. Morris French. Physicians have also come to Butler from Pittsburg and many surrounding towns, and a small army of over 100 trained nurses has been hurried in to the relief of the city. The physicians of Butler have from the beginning been in the forefront of the relief work and have sacrificed unsparingly their time and strength with the same single-mindedness so often shown by members of the medical profession in times of great emergencies. Although much outside assistance has been rendered, there is still need for additional help in this direction, and strenuous attempts are still being made to obtain additional nurses and other assistants.

Rumors have been current regarding dissensions among those engaged in the relief work, and in view of these statements the following authorized statement has been issued by the secretary of the executive committee:

I am authorized by the executive committee to state that the reports emanating from unreliable sources published in various papers throughout the country to the effect that the different relief committees and auxiliary committees were not working in unison and that there is conflict and confusion among the members of the committee and coworkers are absolutely false in every particular.

The organizations that have been established within the past week for the relief of the fever victims are working in perfect harmony and there are no dissensions of opinion on account of religious or political creeds.

We are organized for the sole purpose of relieving charitable fever patients and to do all in our power to assist the municipal and other authorities in stamping out the epidemic. The committees are working as a single individual and all the reports to the contrary are absolutely false in every particular. We wish further to state that Mayor Kennedy is an honorary member ex-officio of the executive committee, and is acting in perfect harmony in all matters.

POSSIBLE SEQUELÆ.

As is usual in epidemics of such magnitude as the one now raging at Butler, a considerable amount of secondary infection is to be feared. Already several nurses and physicians and others engaged in relief work have fallen victims to the disease, and even with the utmost precautions it seems not unlikely that cases of typhoid fever will continue to develop. The great attention being paid, however, to methods of thorough-going disinfection should go far to minimize the danger from this source.

Since the sewage of Butler is discharged into Connoquenessing Creek, and since several other communities further down the stream derive their water from this source, great concern has been expressed lest further infection of other communities might be brought about by this means. To forestall this possibility the State Board of Health promptly issued warnings to the towns located along the lower part of the creek, and so early and so great was the publicity given to the matter in this way that it is hoped that the further widening of the Butler calamity may be averted.

TUBERCULOSIS CONGRESSES.

Last week we printed a communication which called attention to an unsatisfactory condition of affairs, which, while it has been appreciated by all who are acquainted with the facts, was and is being too much ignored by the profession as a whole. It is well known by those who have been giving attention to the subject that the so-called congress on tuberculosis, which has met for the past two or three years in New York, was controlled by those who did not have the confidence of the profession; that it was not noted for its scientific character, but rather for the chance it gave for the exploiting of advertising schemes, fads, etc.

At the last meeting of that "congress" a new set of officers was elected, and while these had not been recognized as authorities on the tuberculosis question, nevertheless it was thought that there was a promise of better things. A meeting was set for July, 1904, at St. Louis, but recently this has been changed to April, 1905, at Washington.

It soon developed, however, that the deposed officers of the former congress were attempting to get up another organization, and they are now arranging for a meeting to be held at St. Louis in October, 1904. The officers of this congress, called the "Bell Congress" by Knopf, have been extremely energetic, for they have not only succeeded in getting delegates appointed by the presidents of state medical societies and by the governors of the states, but have even obtained the sanction and indorsement of the United States Government, and through the State Department are obtaining the official support of our foreign representatives. According to a circular before us, official notification in regard to the "congress" has been sent to all our ministers and foreign representatives. Judging from a letter dated November 3, from the Assistant Secretary of State to Mr. Clark Bell, the letter copied below is "a copy of the instructions sent to Ambassador Choate. The instructions to France, Denmark and The Netherlands are *mutatis mutandis* in the same language." The following is the letter:

Sir:—The Department is informed by Mr. Howard J. Rogers, Director of International Congresses of the Universal Exposition to be held in St. Louis in 1904, that the American Congress on Tuberculosis has been placed on its list of official Congresses and that the dates for said Congress will be October 3, 4 and 5, 1904.

The Department is also advised by Mr. Clark Bell, Chairman of the Committee of Organization of the Congress, that the Executive Committee and Officers of the Congress have sent to the Government of each American Country an invitation for official representation by its Government, in the Congress; and the request is made of the Department to give such support to the invitation as it properly may.

The humanitarian object which this Congress has in view to reach, by the discussion of scientific men, some result in arresting the spread and averting so far as it may be found possible the ravages of this dreadful disease which now falls with such terrible force and fatality upon the people of the Western Hemisphere can not but enlist the sympathy and approval of the Government to which you are accredited.

The Department will, therefore, be pleased to have you say to that Government that this Government is in entire sympathy with its work and would be pleased to learn that the Government of ——— took a like interest in its success by the acceptance of the Committee's invitation, and the appointment of three or more scientific gentlemen to represent it at the Congress.

This Government would also be pleased if that of ——— could find it convenient to comply with the request of the Committee to give the matter publicity in order that it may come to the knowledge of interested organizations and public spirited Citizens of that Country. I am, Sir,

Your obedient servant,

&c., &c.

This letter, without referring to others, is sufficient to show how seriously and earnestly the United States Government has endorsed the movement. The fact that these people have succeeded in obtaining the support of the Government is unfortunate, for as a natural result physicians of foreign countries interested in the subject will be led to come to this congress. If, having come so far, they find that the "congress" is not supported by the better element of the profession—by those prominent in tuberculosis work in the United States; if, to use a familiar expression, they find the play of Hamlet with Hamlet left out, they will feel that they have been imposed on. The results will not be complimentary to us, but will in a measure reflect on the medical profession of the United States, irresponsible as it is for the conditions.

We are neither ready, nor is the time opportune for an international congress on tuberculosis. But when we have one, let it be one that shall have its inception in some reputable and recognized body; one that shall have the indorsement and support of the profession, and especially of those who are recognized as authorities on the subject; one whose utterances shall be authoritative and command respect, and one that shall redound to the credit of America and of which Americans can be proud.

We believe that those who are working in behalf of the organization known as the Lewis-Brown congress are animated by pure motives, and by the belief that its contemplated meeting will be beneficial. Nevertheless, we can not but think that under the circumstances it will be a mistake for them to go on. They have inherited with their "congress" all its former stigma, and the only way to get rid of the stigma is to quietly let the "congress" die and start anew. The title of the Lewis-Brown congress—The American Congress on Tuberculosis for the Prevention of Consumption—is too much like that of the Bell congress—The American Congress on Tuberculosis—and it will be impossible for

them to free themselves from the odium the name carries with it.

As far as the other congress is concerned, the so-called "Bell Congress," it seems to us that the time has come to do something more than simply ignore it. If it is to become a reality under conditions in which it can not receive the support and co-operation of those best qualified to represent the American medical profession in the discussion of the subject, and we believe such to be the case, it is well that the world should know the fact.

MARMOREK'S VACCINE AND SERUM FOR TUBERCULOSIS.

We called attention last week to the fact that Dr. Alexander Marmorek, until recently one of the laboratory chiefs of the Pasteur Institute, Paris, presented a paper to the Academy of Medicine on November 17, in which he described a vaccine and a serum for tuberculosis. The French medical journals containing full abstracts of the paper have now been received.

Marmorek will be remembered as the bacteriologist who, some ten years ago, discovered antistreptococcus serum, and whose investigations in bacteriology have been generally considered of great value. Since he began his studies on the serum for tuberculosis, owing to a difference of opinion with the other members of the staff of the Pasteur Institute, he has resigned his position there and this work has been carried out, and the paper presented, on his own responsibility. While his conclusions can not yet be accepted as proved, there is a possibility that he has made a discovery, or series of discoveries, of prime importance with regard to the toxin of tuberculosis and the biologic method by which the affection may be relieved if not eventually cured.

Marmorek began his present investigations convinced that tuberculin was not the true toxin of the bacillus of tuberculosis. The observations that it fails to cause any reaction in normal individuals, yet produces a marked reaction in those suffering from a mild form of tuberculosis, and only a slight reaction, sometimes none at all, in those suffering from the severer forms of tuberculosis, are a series of contradictions that can not, he holds, be reconciled on any theory of the action of this supposed toxin. Beside, the reaction after an injection of tuberculin usually does not occur for several hours and sometimes longer. Marmorek considers, then, that the rôle of tuberculin is to cause an excitation of any tubercle bacilli present, as a result of which they produce the toxic materials whose absorption brings about the febrile reaction. Tuberculin acts, to use his figure, somewhat as a key does in a lock unlocking the latent toxic powers of the tubercle bacilli present. With this view in mind Marmorek looked for another toxin of the tubercle bacillus and believes he has succeeded in finding it.

He considered it especially important to have the tubercle bacilli in his culture media maintain the staining characteristics which they originally possessed. Any modification of this he considered due to an alteration in their vitality. The only medium on which he could grow successfully these "primitive," as he calls them. tubercle bacilli, was a leucotoxic serum obtained by injecting the white cells of smaller animals into the calf. To this leucotoxic material was added bouillon made from the liver of animals and a slight amount of glycerin. The reason for using the liver bouillon is that this organ seems to be especially refractory to attack by the tubercle bacillus. Hence, Marmorek argues, when tubercle bacilli can be made to grow on liver bouillon, they retain their vitality and virulence to a marked degree.

Bacilli thus grown produce no tuberculin but do produce another toxin. Rabbits especially can be immunized against infection with tubercle bacilli by a properly directed dosage of this toxin. When thus immunized their serum is distinctly antitoxic. This is the serum which, produced in large quantities from horses, Marmorek has used in his observations on the cure of tuberculous animals, including human beings. While working at the serum he succeeded in producing also an antituberculous vaccine. When tubercle bacilli are treated for a long time with leucotoxic serum, and after being heated are added to the antituberculous serum, they are, when injected into animals, absorbed without the formation of abscesses and without causing any general infection. When thus injected they act as a vaccine against subsequent tuberculous infection. The immunity thus obtained has lasted in the rabbit for two months to date.

With tuberculous animals, Marmorek asserts that he has obtained excellent results with his serum. While control animals died or became very ill from tuberculosis, those treated by the serum or the vaccine developed no tuberculosis, or quickly recovered from the incipient stages of experimental tuberculosis. With regard to human beings, his results, he says, are quite as promising, though, necessarily from the limitations of the experimental method, not as definite. At first, of course, he was able to secure for treatment only very far advanced cases. In a number of cases of tuberculous meningitis there was a prompt improvement of symptoms after the injection of the serum, the pulse and temperature were reduced, the paralysis became less marked, even the coma came to an end. But none of the patients survived ultimately the ravages of the disease. In advanced cases of tuberculosis of the lungs, even when there existed cavities and abundant expectoration containing many bacilli, the improvement was very marked and some patients have even been apparently cured, though, of course, a sufficient length of time has not yet elapsed for the definite announcement of a cure.

In surgical tuberculosis, that is, of the bones, the lymph glands, the intestines and the peritoneum, some encouragingly satisfactory results were obtained. Complicated cases of Potts' disease with fistulas and abscesses, and even in one case with paralysis of the lower limbs

apparently due to pressure of a tuberculous process on the cord, were treated, Marmorek asserts, with prompt relief of symptoms. In the affection which may be considered on the borderline between medicine and surgery, tuberculous pleurisy, the effect of injections of the serum was very marked. Out of 7 cases, 2 of them in little children, 6 improved at once, showing a rapid diminution of the transudate associated with a very free secretion of urine and a termination by what Marmorek considers a urinary crisis.

In more than 2,000 injections, there seems to have been no untoward symptoms observed; only three times was there a local abscess. The serum is said to cause no fever and no other local or general reaction occurs. Hectic fever is affected favorably by the antituberculous serum after two or three injections. Far from fever being a contraindication to the use of the serum, it is this class of cases particularly that Marmorek has preferred to treat, since the demonstration of the antifebrile action of the serum is a prominent feature of the treatment. Marmorek does not consider that his results are absolutely conclusive, but contends that there is no longer any doubt that the method is worth while trying extensively.

The fact that Marmorek's former colleagues in the Pasteur Institute discredit the results, at least to a considerable extent, is sufficient to make us receive these reports with some caution, and we shall wait for further developments before expressing any opinion in regard to this discovery and its value in tuberculosis. The announcement, however, is one of considerable interest as it stands and we, therefore, are glad to furnish it to our readers.

SUGAR METABOLISM AND DIABETES.

When Pawlow demonstrated that pancreatic juice as secreted into the intestine in an inactive form is rendered active by another ferment, *enterokinase,* secreted by the intestinal mucosa, he did more than give a new light on the processes of digestion in the intestine, important as that contribution was. He also pointed the way to new researches that might show other examples of the interdependence of organs and cells. One of the fruits of this research seems to have matured in the very important discovery of O. Cohnheim[1] concerning the mechanism and the agents concerned in sugar metabolism, apparently a discovery that clears up at last one of the most fundamental processes of metabolism which has evaded solution in spite of much work directed to that end. It is indeed strange that the history of sugar in the body has not been completely worked out long ago, in view of our familiarity with its chemical properties and structure, and the large quantities that the body daily utilizes. We have long been familiar with certain steps in its metabolism, knowing that in whatever form it is ingested it is absorbed as a monosaccharid; that a fairly constant amount is maintained in the blood through the ability of the liver and muscles to convert any excess into glycogen and to restore it whenever there begins to be a deficiency; and also that if the sugar in the blood greatly exceeds the normal amount it begins to escape into the urine. We also knew that sugar was the chief source of heat and energy, which it furnished by undergoing destructive oxidation; and as the chief place where heat and energy is produced is in the muscles it was probable that the oxidation took place within the muscle cells. Yet experimentally it had not been possible to demonstrate any such property in muscle tissue. It was known that glycolytic ferments exist that have the power of destroying sugar, but extracts prepared from muscles in various ways were found to have no such property, or at least not enough to begin to account for the enormous destruction of sugar that the body accomplishes every day. And so, despite the apparent certainty that the muscle tissue was the seat of an active glycolysis during life, the agents concerned could not be found within them by experimental means.

Another set of facts implicated the pancreas, beginning with the classical observations of von Mering and Minkowski that removal of the pancreas led to severe glycosuria in the lower animals, up to the recent observations of our American scientists—Opie showing that of the different elements of the pancreas, the islands of Langerhans are the chief and probably the sole structures concerned in human diabetes, and Herter, that reducing bodies of any kind applied to the pancreas cause the appearance of sugar in the urine. It was also known that in animals in which the pancreas is thrown out of function, as well as in human pancreatic diabetes, the sugar accumulates in the blood instead of being oxidized, and from this accumulation results the glycosuria. Evidently, then, the pancreas is essential for the oxidation of sugar, and it might well be imagined that among the many enzymes it produces is one that has this property, but as with the muscles it has been impossible to demonstrate any such enzyme in the pancreas. It remained for Cohnheim to put these facts together; considering the peculiar change brought about in a pancreatic zymogen, trypsinogen, by the action of another ferment contained in the succus entericus, whereby the inactive zymogen is converted into trypsin, he came to appreciate the possibility of some similar interrelation of pancreas and muscles. Experiments were made along the lines thus suggested, with most successful results. It was readily demonstrated that although extracts of either pancreas or of muscle made by expressing the juices of the cells by a powerful press, were practically without effect on glucose when each was taken alone, yet when combined the resulting mixture was able to destroy the sugar rapidly and in time completely. Furthermore, the amount and rate of glycolysis shown by muscle extract is sufficient to account

1. Hoppe-Seyler's Zeitschrift f. Physiol. Chemie, 1903, xxxix, 336.

fully for all the oxidation of sugar accomplished by the body during the day.

Putting together all the facts now acquired it would seem that in the islands of Langerhans is formed a substance which is like a ferment in nature, as it is destroyed by heat. This substance passing to the muscles through the blood stream meets in the muscle cells another ferment or proferment, and between them a reaction occurs resulting in the formation of a ferment that has the power of rapidly destroying sugar. This is similar to the activation of trypsinogen by the intestinal product, enterokinase, and in turn it has been shown by Delezenne that the reaction of enterokinase and trypsinogen is quite similar to the combining of complement and intermediary body as it occurs in the cytolytic and bacteriolytic serums. It would seem, therefore, that in pancreatic diabetes we have an absence or a deficiency of the specific secretion of the islands of Langerhans that is necessary to make the glycolytic substance of the muscles active. Of course, this does not exclude the possibility of a similar combined effect with substances in any other tissues of the body where sugar is burned. The unknown ferment that results from the action of pancreatic and muscular zymogens seems to be specific for dextrose, for in diabetes other sorts of oxidations seem to be impeded little if any. As Cohnheim's results, which seem to be unquestionable, are amplified, and we know more about the intermediate steps and the places of normal glycolysis, as well as the nature of the pancreatic and the muscle agents implicated, it is probable that we shall understand better than was possible before the essentials of the pathogenesis of human diabetes.

Perhaps the most remarkable thing about Cohnheim's discovery is its simplicity, the usual characteristic of real discoveries. For years physiologic chemists have been trying to put the sugar destruction on the pancreas or on the muscles, knowing each to be concerned, but in vain. Why it had not before occurred to any one that it might be the work of the two together is the chief mystery. Now that the suggestion has been made and followed out the entire difficulty clears up, and we have a most reasonable and simple explanation of a long perplexing problem, as well as a new field for fruitful research.

DERMOID CYSTS AND TERATOMAS OF THE ANTERIOR MEDIASTINUM.

It is in the diagnosis of obscure pathologic conditions that the physician of unusual ability is distinguished from the ordinary physician. Among such conditions may certainly be mentioned the dermoid cysts and teratomas of the anterior mediastinum. Dangschat,[1] an assistant in Garré's clinic in Königsberg, gives practically all the information obtainable on this subject up to this date. He reports two cases operated on in the Königsberg clinic and has collected from the literature forty-four similar cases. Only two of these are from American journals, one reported in 1879, and three others are mentioned from English sources.

Various theories have been advanced to account for the origin of these tumors. The origin by direct embryonic inclusion, by development from the thyroid or thymus or from the gill-slits, Dangschat rejects on the basis of careful examination of the material obtained at operation in these cases. The new growth contains tissue which had its origin in all three of the germ layers, and he believes that this makes *inclusio fœtus in fœto* the only possible origin. The chief danger from such inclusions is through the rapid growth of their contents with degeneration of the walls surrounding them, and the symptoms generally first appear at about the time of puberty. The growth usually continues for several years and is much slower than that of sarcoma and carcinoma. Difficulty in breathing is the most important symptom of these dermoids, and with it there is often considerable pain. In a considerable proportion of cases there was cough and expectoration, and in a few cases spitting of blood. As the growth increases in size the prominence of the chest wall is noticeable. Earlier in the disease the picture may resemble that of tuberculosis of the lungs, but at a later stage the diagnosis would lie between pleurisy with effusion, aneurism, echinococcus, and actinomycosis. The finding of hairs in the sputum furnishes positive diagnostic proof. In many other cases puncture with an aspirating needle would clear up the diagnosis.

When the history leads to a probable diagnosis of dermoid cyst, operation should be undertaken. The aneurismal bruit and the symptoms of inflammation in actinomycosis would probably leave little doubt as to the differential diagnosis from these conditions. The prognosis is absolutely unfavorable unless a timely diagnosis is made and suitable operation undertaken. The operation in most cases necessitates resection of several ribs, or of the sternum, an evacuation of the cyst and suture of the remaining cyst wall into the opening. The cavity then is scraped with a curette or treated with caustic and left to close by granulation. In three of the cases out of forty-four death followed the operation, in one case from hemorrhage, in the second from infection, and in a third from an unknown cause. The remaining patients were either cured or improved.

In several abstracts of cases which Dangschat gives, the cavity left after operation was of very large size. Such cavities could hardly be expected to close after operation unless something further were done. It would seem that in such cases the cavity might sometimes be partially or entirely closed by turning in large skin flaps from the surrounding region after the wound was well covered with healthy granulations. Failing in this the use of large Thiersch skin grafts might be considered.

1. Beiträge zur klin. Chirurg., 1903, xxxviii, p. 692.

THE OWNERSHIP OF THE PRESCRIPTION AGAIN.

The newspapers announce that a druggist in New York was recently compelled to deliver a prescription to a patient, the latter claiming that he was entitled to it, and the claim being upheld by a lower court. This has started the vexed question on its rounds again and the newspapers are, as usual, deciding the matter for us. At times the question as to who owns the prescription is an important one, not only for the physician, but for the patient. For instance, if a physician writes a prescription that contains an ingredient that may be harmful if its use is continued, it is very important that he should have the right to say whether it should be refilled, or whether it should be delivered to the patient. The fact is, after all is said about the matter, the prescription is simply a letter—a note—to the chemist instructing him to do certain things. The physician may write this letter in the common prescription form or he may send a note addressed to Mr. Brown, the druggist, asking him to give the bearer, Mr. Smith, an 8-ounce bottle of compound syrup of sarsaparilla. There is no reason why the patient should have this letter back, any more than if he were given a letter to a merchant asking that he let Mr. Smith have any specified article. Again, the physician may, and often does, telephone to the druggist telling him to put up a certain combination for Mr. Smith, who will call. Or, he may send his office-boy to the druggist with a verbal message for medicine for Mr. Smith, or he may give Mr. Smith medicine direct from his own office stock. The fact is, no one owns the prescription. The druggist has no right to give it to anyone without the physician's direction, and he has no right to refill it without the physician's orders. One newspaper, as an argument to show why the patient should own and have the prescription, says that some prescriptions are very valuable and, having to pay for it, the patient is entitled to it, not only to use for himself, but for his friends. This is a splendid argument, but on which side it should be placed depends on the point of view.

THE CASE OF THE "MODERATE DRINKER."

In a recent inquest in New York, according to press reports, a man has been declared as having died of "refined alcoholism." He was suddenly stricken after a surgical operation and died from what was alleged to be delirium tremens. He had been supposed to be of temperate habits, taking only moderate drinks at morning and night, but it would appear that his system had become disorganized, if not saturated, by the agent and the effects on the nervous system were such as to bring about these results. The verdict may have been a correct one, and based on facts presented. It has long been recognized that alcohol in any dose is not a safe prescription for certain constitutions, but its possibilities of danger have seldom been fully realized. The fact that a large number of persons can apparently thrive while more or less under its influence is no proof that this is the case with all and it is probable that if we had all the facts in every case we would find that those who appear to do well under its habitual use are really none the better for it. Like other poisons, it produces in some constitutions a sort of habituation. In still other cases the resistance is so strong that its effects are not manifest, but may appear later in transmission to offspring. That alcohol is an influence for good in certain cases is undoubtedly true, but the assertion that it adds to the sum of human happiness can be reasonably criticised. It would indeed seem absurd in view of the immense amount of evil that it creates, but with the almost universal use of alcohol throughout the world in some form or other its advocates have certain specious grounds for their position. Nevertheless it may be, like certain diseases which are accompanied with a special euphoria, as damaging in one case as in another. If all men could get the exalted delusions of paresis the sum of human happiness would certainly be greatly increased for a time, but it would only mean irreparable damage to the nerve centers. We may say the same of the pleasures of alcohol, and if it is dangerous to the system, is followed by reaction and tends to racial and individual degeneration, all these things ought to be considered before we speak of its advantages.

Medical News.

MARYLAND.

Epidemic Ends.—Dr. J. H. Drach, Butler, health officer of the Mount Carmel district of Baltimore County, reports that the diphtheria epidemic there is at an end, and that no further deaths have been reported. The epidemic was much aggravated by a dread of antitoxin for a time by the people.

The Same Old Disease.—A "mysterious contagious disease," variously diagnosed as "smallpox," "chicken-pox" and "Cuban itch," has been prevailing for some weeks in Frederick, Clarke and Jefferson counties, just across the Maryland border. Whole communities are in quarantine, and it is being treated as smallpox.

Requested Not to Spit on Sidewalks.—A committee, consisting of Drs. James W. Humrichouse, Hamilton K. Derr and Luther H. Keller, of the Washington County Medical Society, appeared before the mayor and city council of Hagerstown, December 3, and asked that placards be placed on the street corners, public buildings, street cars, etc., requesting the people not to spit on the sidewalks and floors.

Personal.—Dr. Elijah Williams, Armiger, Anne Arundel County, formerly state senator, has been appointed school commissioner, vice James E. Tate.——The Baltimore county commissioners have appointed Dr. Thomas C. Bussey, physician of the almshouse, and Dr. J. Royston Green, physician of the county jail.——Dr. Samuel T. Heffner has been elected clerk of the Circuit Court of Frederick County.——Dr. George Wells has been re-elected clerk of the Court of Appeals at Annapolis.

Baltimore.

Typhoid at Army Post.—There are eleven enlisted men at Fort McHenry ill with typhoid fever.

Senses Hospital Incorporated.—The tenth Baltimore Eye, Ear, Nose and Throat Charity Hospital was incorporated, December 3, with Drs. James Bordley, Jr., and Harry E. Peterman as attending surgeons. A central site will be selected for the institution.

Appropriations for State Institutions.—The state institutions have put in application for state aid, with the Board of State Aid and Charities, amounting to $2,724,990 for the next two years. The amount now being received by these institutions for the same period is $1,293,382.

November Mortality and Morbidity.—The mortality report for November shows 756 deaths. Pulmonary tuberculosis leads with 102; next comes pneumonia, with 94; heart disease, 69; Bright's disease, 67; cancer, 27; diphtheria, 21, and typhoid fever, 19. Diphtheria and scarlet fever were the most prevalent infectious diseases.

Thousands for Charity.—Nine thousand one hundred and fifty-six dollars was realized for charity at the annual banquet

of the Hebrew Benevolent Society December 3.——A Christmas sale for the benefit of the Crippled Children's Hospital was held at the Arundel Clubhouse December 4 and 5.——The fair held at University Hospital last week by the Ladies' Auxiliary realized more than $1,700.

Reappoints Medical Department Staff.—Dr. James Bosley, health commissioner, has reappointed the medical officers of his department, including Dr. C. Hampson Jones, assistant commissioner; Dr. W. Royal Stokes, bacteriologist; G. W. Lehman, chemist; Dr. Nathaniel G. Keirle, medical examiner; Dr. Bernard P. Muce, assistant examiner; Dr. Alan W. Smith, throat inspector; Dr. Sydney O. Heiskell, quarantine physician, and Dr. Thaddeus W. Clark, assistant quarantine physician.

Personal.—The governor has reappointed Dr. William H. Welch president of the State Board of Health.——Dr. Albert D. Foster of Detroit has assumed charge of the immigrant service of this port and has reported for duty as surgeon, vice Dr. W. M. Glover, transferred to Victoria, B. C.——Dr. William N. Bispham, post physician at Fort McHenry, has been ordered to take charge of the hospital at Fort Logan, Colorado. He will be succeeded by Capt. Edward R. Schreiner of Fort Howard.

Munificent Bequests.—Mr. William Wyman, the benefactor of the Johns Hopkins University, through whom that institution received one year ago a magnificent tract of land in the northern suburbs, and a contribution of $1,000,000 from the community, died last week. By his will he leaves his entire estate, estimated at $500,000, less $108,000 in special legacies, to his daughter, who is a widow, and in the event of her death to Johns Hopkins University.

Filtration System Recommended.—A special sewerage report, submitted to the mayor and board of estimates by the city engineer and water engineer, recommends the filtration system at an expense of $6,000,000. The commission estimates that not over 50 per cent. of the water consumption will get into the sewers. The estimate is for a million population, and provides for the present only pumping machinery, discharge mains and filtration fields for 600,000, which is slightly in excess of the population of the city. "Each property should only be directly charged with the cost of the necessary connection from the house to the sewer, as is now done with the water service."

MASSACHUSETTS.

Sewage Disposal.—The city council of Fitchburg has voted the sum of $445,012 for the construction of new sewage disposal beds.

Insane Hospital Reports.—The Worcester Insane Hospital reports a daily average of 1,125 patients; $83,700 is asked of the legislature for needed additions and alterations.

How Scarlet Fever is Spread.—Two cases of scarlet fever, so mild that they were not discovered till the "peeling" stage, have caused a large series of cases in West Springfield.

Scarlet Fever Closes School.—The illness of a teacher with scarlet fever in the high school at Danvers, together with the unusual prevalence of the disease, has closed the school for the present.

Physician and Nurses Exonerated.—The trustees of the State Hospital at Tewksbury have decided that the recent poisoning of several men by belladonna or atropin was the result of the act of some degenerate or criminal inmate. The nurses and physicians are completely exonerated.

Anthrax Treated at Lynn.—Of the four cases of anthrax recently treated in Lynn, three patients recovered. One of these refused operation with free excision employed in treating the others, and received instead carbolic injections under the skin and mercuric chlorid applications wet and dry.

Leaves Estate for Hospital.—Stephen Symmes left his estate to the town of Arlington for the establishment of a hospital. As the location proved to be unsuitable, the Supreme Judicial Court gave permission to sell the property, and the $4,700 thus realized will be employed toward the erection of a hospital.

Tuberculosis Fund Exhausted.—The Massachusetts fund to pay farmers for tuberculous cows condemned by the state cattle bureau has been exhausted. As a result 200 diseased cows have been released from quarantine. No further work can be done till a new appropriation is secured from the next legislature.

Spring Water Causes Typhoid.—The occurrence of a number of cases of typhoid fever in Springfield, Mass., recently noted, led to sending samples of "spring water" sold in the city to the State Board of Health for analysis. Their report absolutely condemns seven springs, five of them located in the public park system. Several other springs are below standard and the owners have been warned. Springfield has a good municipal water supply, but owing to the color of the water many citizens have been buying their drinking water from the owners of these contaminated springs. The epidemic of typhoid was promptly checked by the measures taken by the local health board.

The Williamstown Epidemic.—The report of Dr. George A. Soper, the sanitary engineer of the New York Board of Health, summoned to Williamstown by President Hopkins, shows that the recent outbreak of typhoid fever at Williams College was caused by infected cream eaten with breakfast food. The can of cream was placed in a vat of contaminated water to cool, and became itself accidentally infected.——The final step in regard to the typhoid fever at Williamstown has been for the boards of health of that town and of North Adams, which adjoins, to call on the State Board of Health. Drs. S. L. Morse and William S. Johnson have accordingly been sent to investigate thoroughly the typhoid situation in both places.

Boston.

The "New Boat" Fund of the Boston Floating Hospital has reached $5,895.

Bequest.—George O. Smith left by will $5,000 to the Massachusetts General Hospital.

Music at Hospitals.—During December musicians employed by the Hospital Music Fund will visit the Woman's Charity Club Hospital, New England Baptist Hospital, and the Children's Hospital.

Building Nearly Ready.—The new building for the Industrial School for Crippled and Deformed Children, in which many Boston physicians are interested, located on St. Botolph Street, near Massachusetts Avenue, is nearly completed. The quarters on Newbury Street have been overcrowded for more than three years.

Hospitals Benefit.—By the will of George W. Boyd of Boston the Children's Hospital receives $5,000.00; the Maine General Hospital $7,500, and under certain conditions the Massachusetts General Hospital $25,000. The residue, which is likely to amount to about $100,000, will be distributed to charitable organizations at the discretion of the executors.

The Convection of Typhoid.—C. E. A. Winslow reported before the last weeting of the Boston Society of Medical Sciences that examination of the hands of school children, students and servants showed the presence of colon bacilli in from 5 to 10 per cent. of the individuals examined. The experiment was used as a side-light in the way in which typhoid bacilli are transferred from case to case.

Death and Disease.—The total number of deaths in Boston for the four weeks ended December 5 was 763, 75 less than in the corresponding period last year. The annual death rate was therefore 16.48 per 1,000. Of these deaths 100 are from pneumonia, 3 from whooping cough, 100 from heart disease, 28 from bronchitis, and 15 from marasmus. There were reported 238 cases of diphtheria, with 22 deaths; 131 cases of scarlet fever, with 1 death; 77 cases of typhoid fever, with 16 deaths; 474 cases of measles, with 9 deaths; 128 cases of tuberculosis, and 90 deaths, and 1 case of smallpox.

MINNESOTA.

Hospital Incorporated.—St. John's Hospital, Red Wing, has been incorporated with a capital stock of $35,000.

Smallpox.—For the week ended November 23, 28 cases of smallpox were reported, 10 of which were from Maine Prairie Township, Stearns County.

Campaign Against Tuberculosis.—A committee on organization to carry on the fight against tuberculosis in Minneapolis and St. Paul, has been appointed, consisting of eleven physicians and five laymen, with Dr. Henry M. Bracken as chairman.

To Placard Consumptive Homes.—An ordinance prepared by Dr. E. H. Whitcomb, assemblyman of the St. Paul City Council, provides that all physicians shall report cases of tuberculosis to the health commissioner. Houses where consumptives have died or from which they have moved will be placarded with the information that they are infected. The ordinance will be proposed for passage.

NEW HAMPSHIRE.

Unregistered Practitioner Fined.—Ferdinand Alfred Trudeau, Somersworth, was arrested, November 11, charged with the un-

authorized practice of medicine. He pleaded guilty, was sentenced to imprisonment for three months in the county jail, and to pay costs, and the sentence was suspended on promise of good behavior.

New Hospital.—Exeter is to have a fine new hospital at a cost of $20,000. Plans have already been accepted for a brick building of two stories in height, with two long wings one story high, one for medical, the other for surgical cases. Broad connecting corridors and wide verandas will join the buildings and furnish out-of-door protection for isolation and fresh air.

Many Offices for One Man.—The mayor of Nashua, in investigating a suit brought against the city by Dr. Charles E. Congdon to recover $1,625 claimed to be due for services rendered, states that he has discovered that the plaintiff was drawing four different salaries and holding four different offices at the same time, namely: city physician, $500 per year; member of the board of health, $100 per year; physician in charge of smallpox patients, $10 per day, and inspector for the board of health, $3 per day.

Urge State Sanatorium for Consumptives.—At its 84th annual meeting held in Lisbon, November 12, the White Mountain Medical Society unanimously adopted the following preamble and resolution:

WHEREAS, From 75 to 80 per cent. of the people affected with consumption are among the poor, who are unable to place themselves under scientific medical and sanitary treatment, without help, and whereas the only hope of such help is through state aid, and

WHEREAS, As this is a question of utmost importance to physicians, humanitarians, and in fact all people who are interested in the welfare of the state, be it

Resolved, That the White Mountain Medical Society emphatically endorses the movement looking towards the establishment of a state institution for the cure and treatment of this class of unfortunate human beings.

NEW JERSEY.

Personal.—Dr. J. Alexander Browne has been elected health officer of Paterson, vice Dr. Bryan C. Maginnis.——The governors of the Atlantic City Hospital have appointed Dr. W. W. Miller, Philadelphia, a graduate of Jefferson Medical College, resident physician, to fill the vacancy made by the resignation of Dr. Milton Ireland.

The Mosquito Must Go.—A national anti-mosquito association is announced to be organized at a meeting, December 16, under the auspices of the governor of the state. Representatives of the Department of Entomology at Washington, and delegates from several states are expected to be present. Plans are to be formulated for the extermination of the pest.

To Regulate Barbers.—The Atlantic City Board of Health has adopted rules for the proper regulation of barber shops, which in brief are as follows: Barbers must wash hands before attending each patron; styptics to be used in powder only; no powder puffs; towel for one person only; no sponges; mugs and brushes washed after each use; combs, razors, etc., cleansed after each use; floors swept or mopped every day; hot and cold water in every shop, and conspicuous display of regulations in each shop.

Officers Elected.—At the annual meeting of the William Peirson Medical Association of Essex County, the following officers were elected: President, Dr. Thomas W. Harvey, Orange; vice-presidents, Drs. Richard C. Newton, Montclair, and Joseph C. Young, Newark; secretary, Dr. Richard D. Freeman, South Orange; treasurer, Dr. John H. Bradshaw, Orange; librarian, Dr. Henry A. Pulsford, South Orange, and council, the officers, and Drs. William B. Graves, East Orange, Mefford Runyon, South Orange, and Theron Y. Sutphen, Newark.

Epidemics.—Diphtheria is said to be epidemic at New Brunswick, where 35 cases have been reported. It is asserted that the epidemic originated in the concealment, by a physician, of the first case.——A "strange disease, resembling scarlet fever, but more rapid in causing death," is said to be raging in Helmetta. Seven deaths have occurred, the public schools have been closed, and an isolation hospital has been established.——Four cases of smallpox have been discovered in a tenement house in Hackensack.——Camden has four cases of smallpox in its isolation hospital.

NEW YORK.

Epidemic Feared.—An epidemic of diphtheria is feared at Inwood, Long Island, where nine cases have occurred, with two deaths.

Personal.—Dr. Edward F. Brush, mayor of Mount Vernon, has appointed Dr. Archibald M. Campbell, president of the board of health.

Octogenarians Still Practice.—Syracuse has four physicians each more than 80 years old who are still in practice. They are Drs. Alexander Jones Dallas, a graduate of 1844, Edwin Robinson Maxson and Alfred Mercer, who began practice in 1845, and Henry Darwin Didama, who has been in practice only since 1846.

Smallpox.—The State Health Department, on November 28, issued a list showing the prevalence of smallpox and stating that health officers are generally alive to the situation, but receive indifferent support or actual opposition from local boards and citizens in the enforcement of vaccination and quarantine. At Medina there are 92 cases, and one or more cases are reported from 12 other places.

Authorities at Variance.—Dr. Charles S. Howard, president of the board of managers of the Elmira Reformatory, says that there were 80 cases of diphtheria during a certain period; Superintendent Robertson avers that there were but 53. Dr. Howard believes the typhoid epidemic was caused by city water, used when the reformatory plant was out of order, but Dr. Robertson stated that the water used was filtered.

New York City.

Pneumonia Death Increase.—An alarming increase in the pneumonia death rate in Greater New York, is reported for the week ended November 28, as compared with the corresponding week of 1902.

Personal.—Dr. Louis Schaefer, house surgeon at St. Catherine's Hospital, Brooklyn, on completing his term of service was given a dinner by his associates at the hospital. He is succeeded by Dr. Frank D. Jennings.——Dr. Francis H. Miller, Brooklyn, was painfully injured in a runaway accident December 1.——Dr. Lawrence J. Gerald, of the medical staff of the Long Island State Hospital, has been appointed assistant surgeon at the Soldiers' Home, Bath.

German Hospital Library Fund.—The physicians of the German Hospital and Dispensary, after striving for over thirty years to collect valuable medical books, decided that it was best to dispose of the library. It was accordingly sold to the Kings County Medical Society for $3,000, and this sum was then presented to the New York Academy of Medicine with the understanding that it should be known as the German Hospital and Dispensary Library Fund.

Hospital Items.—The new Plant Pavilion to be added to St. Luke's Hospital is to have the innovation of a roof garden.——The report of the experimental hospital on North Brother Island for the treatment of consumptives is very encouraging. Of the 127 cases admitted to the institution since May 8, 84 have been discharged.——Memorial Hospital, Brooklyn, took possession of its new quarters November 15. It has accommodation for twenty patients.——St. Vincent's Hospital, West New Brighton, Staten Island, was formally opened November 26. The site and buildings cost $35,000.——A new laboratory building and dormitory for Willard Parker Hospital, are planned to cost $100,000.

Buffalo.

The Meltzer Reception.—A reception was tendered to Dr. Samuel J. Meltzer, New York, by Dr. Matthew D. Mann, dean of the medical faculty of the University of Buffalo.

Army Surgeon Buried.—Dr. Charles A. St. John was given a military funeral November 28. He was a contract surgeon in the Army and fell in a skirmish in the Philippines. Although his death occurred two years ago his body reached Buffalo only this week.

PENNSYLVANIA.

Village in Quarantine.—The village of New Benton has been quarantined by the State Board of Health because of the refusal of the authorities to take steps to stamp out smallpox.

The Butler Disaster.—The epidemic of typhoid fever at Butler is fully treated in the Special Article on pages 1476 and 1477 of this issue, written by our special commissioner sent to Butler.

Dr. Pryor in Philadelphia.—On invitation of Dr. John M. Fisher, president of the Philadelphia Obstetrical Society, Dr. William R. Pryor, New York, delivered an address on "Puerperal Sepsis" before that body. He was afterward entertained at a dinner, and a reception and smoker were given in his honor.

Free Lectures on Hygiene and Sanitation.—Under the auspices of the Academy of Natural Sciences, Philadelphia, a series of free lectures on hygiene and sanitation is being given by Dr. Seneca Egbert, professor of hygiene in the Medico-Chirurgical College. The series includes lectures on the fol-

lowing subjects: Hygiene of the Individual; Hygiene of the House; Hygiene of the City and State; Sanitary Education of the Citizen.

Contagious Disease in Philadelphia.—The number of new cases of smallpox has been increasing gradually from week to week. For the week ended December 5 there were 99 new cases with 15 deaths. The department of health continues its crusade of vaccination; the hospitals urge vaccination on all their patients; firms plan to have their employes vaccinated; the press advocates vaccination, but still many foolishly refuse protection. As convincing evidence of the value of vaccination, it is a fact that with the prevalence of the disease few, if any, cases have occurred among the crowded foreign population, they having been compelled to be vaccinated before or at the time of immigrating. Director Martin says that of the many cases at the Municipal Hospital none had been vaccinated. There were also for the week a large number of new cases of other contagious diseases: of diphtheria, 93; scarlatina, 126; typhoid fever, 91. There are in the city a large number of cases of influenza of moderate severity.

VERMONT.

College Burned.—The medical college building at the University of Vermont, Burlington, was burned to the ground, December 2. The loss of $20,000 is covered by insurance.

Much Diphtheria and Scarlet Fever.—On account of the prevalence of diphtheria and scarlet fever in Brattleboro, the public schools have been closed for two weeks.——A case of smallpox in Wilmington has led the selectmen to close the schools and to forbid all public gatherings for a period of two weeks.

College Opens.—The exercises preliminary to the opening of the fifty-first year of the medical department of the university were held, November 28. Addresses were made by President Buckham, and by Dr. William M. Bryant, Ludlow, president of the state medical society, whose subject was "The Ideal Physician."

Unvaccinated Teacher Recovers Salary.—Miss Rose Murray, a teacher in a district school, in which smallpox broke out, who had never been vaccinated and was on that account suspended, has sued the town of Bennington for wages and costs amounting to $56. On November 7 she secured judgment against the town.

State Society Meeting.—The ninetieth annual meeting of the Vermont State Medical Society was held at Bellows Falls, October 14, 15 and 16. The following officers were elected: President, Dr. William N. Bryant, Ludlow; vice-president, Dr. Patrick E. McSweeney, Burlington; secretary, Dr. George H. Gorham, Bellows Falls; treasurer, Dr. Bingham H. Stone, Burlington; auditor, Dr. John H. Blodgett, Saxton's River; board of license censors, Drs. Henry James, Waterbury, Schuyler W. Hammond, Rutland, and J. Sutcliffe Hill, Bellows Falls, and Dr. Henry D. Holton, Brattleboro, delegate to the American Medical Association. The society will meet next year in Rutland.

GENERAL.

Outdoor Tuberculosis Camp for Navy.—Pensacola, Fla., climate having been recommended for consumptives, the Navy will establish a camp there and treat tuberculosis patients by the open air and forced food methods of treatment.

Personal.—Dr. H. C. Sloggett has been appointed medical superintendent of the Hawaiian Territory Insane Asylum. Dr. W. H. Mays has been in temporary charge.——Dr. C. R. McLean was appointed government physician for Lihue and Koloa, succeeding Dr. E. S. Goodhue, resigned.

American Association of Life Insurance Examining Surgeons.—The annual meeting of this association will be held at Atlantic City, N. J., June 6, 1904, under the presidency of Dr. Charles Lyman Greene, St. Paul, Minn. Dr. Denslow Lewis, Chicago, is chairman of the executive committee.

CANADA.

New Montreal Hospital for Contagious Diseases.—The plans of the new Alexandra Hospital have been accepted. It will be erected soon at Point St. Charles, and will cost $100,000.

Personal.—Dr. John W. Scane has been appointed registrar of the Faculty of Medicine of McGill University, Montreal, in succession to Dr. von Eberts, who resigned a short time ago. Dr. Scane recently has been an assistant to the professor of physiology.

Poisonous Drugs Used in Liquors.—The attention of the dominion government and of the Quebec legislature is to be directed to the allegation that poisonous and deleterious drugs are at present being used in the compounding and manufacture of liquors in that province.

McGill To Have Physiology Course Enlarged.—Principal Peterson of McGill University announces that there will very shortly be established a new faculty making physiology as much of an arts subject as it is now one of medicine. In time it is hoped to construct a new building for this faculty.

Annual Report Notre Dame Hospital, Montreal.—During the past official year 2,433 patients were treated, with a mortality of 7.6 per cent. In the out-patient department there were 21,245 consultations, and over 1,000 ambulance runs. The financial affairs were satisfactory, there being a balance to the good of $4,731. The contagious hospital in connection with this institution will be erected in the spring, and a new four-story hospital building in the form of a cross will soon follow. The plans for the latter structure are ready.

Kingston Hospital Troubles.—The board of governors of the Kingston, Ont., General Hospital, on the resignation of Medical Superintendent Haig, who has gone to England, appointed a woman without medical training as superintendent, stating that financial conditions would not permit the appointment of another salaried male superintendent. The three house surgeons are said to have then resigned in a body, refusing to take their orders from anyone but a properly qualified medical man. The medical members of the board strongly opposed the doing away with a medical superintendent.

FOREIGN.

Virchow's Library.—The most valuable portion of Virchow's library has been presented by his widow to the library of the Berlin Medical Society. These six or seven thousand volumes are to be kept separately as the Virchow collection.

The Austrian Trouble.—At the first session of the Austrian parliament protests against the recent aspersions cast on the medical profession were presented by three separate groups of members. The Vienna professors against whom the denunciations were made, to which reference has been made in these columns recently, are all of Jewish extraction, and the whole trouble is probably mainly the result of antisemitic agitation.

The Widal Test in School Inspection.—The German authorities have recently issued a notice to the effect that children suspected of typhoid may have a drop of blood taken from the ear or finger for the Widal test by the medical inspectors, but the consent of the parents must first be obtained and the school authorities notified. Compulsory enforcement of this diagnostic measure must not be permitted under any circumstances.

Personal.—Dr. A. P. Peck, missionary in China of the American Board of Commissioners for Foreign Missions, has been appointed by the Chinese government medical officer in charge of the quarantine station at Taku.——Dr. J. N. Langley has been elected professor of physiology at Cambridge University, England, as the successor of Sir Michael Foster. Dr. Langley, the editor of the *Journal of Physiology*, has been, during the absence of Sir Michael Foster, deputy professor of physiology.

Muenchener Klinikerschaft.—The medical students at Munich have organized a society with this euphonious title. Professor G. Klein was invited to address the first meeting, and spoke on "Physician and Client." The professors and students of Brussels have organized a somewhat similar society and inaugurated an innovation, the "medical day." The meetings of the society are held on the second Saturday in the month, and on that day all the clinics and hospitals are thrown open to the members, the visitors being personally conducted by the professors or chefs de service to the specially interesting cases. It is hoped that out-of-town physicians will also join the society and come up for these medical days as a kind of post-graduate instruction.

Plague Prophylaxis in India Abandoned.—It is reported that England has abandoned the endeavor to stop the ravages of the plague in India by the use of prophylactic injections of serum. Although over two million people have died from the disease in the last few years and commerce has greatly suffered, the authorities have decided that the resistance and ignorant discontent of the natives are too much for them. After trying isolation, segregation and inoculation, the government finds that it is only undermining its power in the country. It would seem that England was as capable of giving a thorough test to the matter as any government, and the results are therefore of practical interest to the United States, as well as other nations which have oriental colonies.

LONDON LETTER.

Increase of Lunacy in Ireland.

From time to time statistics have been published in THE JOURNAL showing an increase of lunacy in Great Britain. But certain Irish figures recently published are still more alarming. At a conference of the Irish District Asylum Committee in Dublin Dr. O'Neill read a paper showing that, notwithstanding a yearly decreasing population, insanity was rapidly on the increase. In 1880 the number of persons under treatment was 250 per 100,000 of the population, whereas in 1902 the figures reached the appalling total of 499, an increase of 100 per cent. Emigration and agricultural depression are undoubtedly special reasons for the increase of insanity. The country had been drained of its manhood, and there is a tendency to the depreciation both of the physical and mental condition of the old people remaining. Importance must also be attributed to the agricultural depression that followed in the track of emigration, the inability to make ends meet, the want of nutritious food, and the necessarily accompanying worry wearing the people down. The excessive use of alcohol is another cause. Of the 34,349 admissions during the last 10 years intemperance was the assigned cause in 3,098 cases. Dietary is another matter of importance. Formerly the staple food of the country was porridge, milk, potatoes and butter, which was wholesome, sustaining and nutritious. Tea drinking in excess was given as an indirect factor in inducing insanity.

Diploma in Tropical Medicine Inaugurated at the University of Cambridge.

The great progress in tropical medicine in this country, shown by the establishment of two schools, one at Liverpool the other at London, the numerous expeditions despatched to the tropics, and the remarkable discoveries made by them are fittingly crowned by the establishment of a "Diploma in Tropical Medicine" at the University of Cambridge. The ordinary medical curriculum is no longer regarded as by itself sufficient to fit graduates in medicine for the special conditions attending practice in the tropics. The special board of medicine propose (1) that an examination in tropical medicine and hygiene be held once a year, or more than once if thought expedient; (2) any person whose name is on the medical register to be admitted a candidate under such conditions as the State Medicine Syndicate may prescribe, provided that a period not less than 12 months shall have elapsed between the attainment by the candidate of a registrable qualification and his admission to the examination; (3) the subjects of examination to be nature, incidence, prevention, and treatment of epidemic and other diseases prevalent in tropical countries, and (4) that a candidate who passes the examination be entitled to a diploma testifying to his competent knowledge of tropical medicine and hygiene. 1. Candidates shall present evidence, approved by the syndicate, that they have diligently attended, at home or abroad (a) a course of laboratory instruction in pathology, including parasitology and bacteriology in relation to tropical disease; (b) a course of clinical instruction at a hospital in which cases of tropical diseases are received; (c) a course of instruction in hygiene and in methods of sanitation applicable to tropical climates. 2. Candidates may present dissertations, memoirs, or other records of work carried out by themselves on subjects connected with the nature, incidence, prevention or treatment of tropical diseases, and such records will be taken into account by the examiners in determining the result of the examination.

Correspondence.

"How to Write a Medical Article—A Plea for Plagiarism."

SAVANNAH, GA., Dec. 2, 1903.

Dr. G. Frank Lydston, Chicago:

My Dear Doctor:—On Saturday last a friend informed me of a communication from you in the *Atlanta Journal* pertaining myself; I tried to secure a copy without avail; and was about to write you yesterday when another gentleman apprised me of another communication from you in this week's issue of THE JOURNAL of the A. M. Ass'n which I had not seen and which I have not yet had an opportunity of reading but was informed of the nature of your communication which was quite an unexpected supprise to me. And without a full explanation from me of the matter, I can appreciate your position.

For several years I have been editing a medical journal, as well as doing a large practice, and have been compelled to rely largely on my stenographer for clerical office details, as well as my proof reading, which I trusted to her care for correction; prior to this incident she has made very few errors or omissions; in fact, she has been painstakingly careful and correct in the work assigned, until I trusted implicitly.

In the preparation of my paper for the Georgia State Medical Association I found that my views and your own on the subject were so near alike that I decided to use a few paragraphs which I "blue penciled" and instructed my stenographer to use and give you due credit for same, noting page and title of your book. I also instructed her to make a carbon copy at the same time and send it to the *Annals of Gynecology and Pediatry*, Boston, which she did, and forwarded same before I had the opportunity of seeing it. I found out at the last moment I could not attend the meeting of the state association and handed my paper over to a friend that night (April 14, 1903).

Complications of a political nature demanded my presence at the meeting on the last day, and in company with several physicians I arrived at the meeting on the last day when the program of the association was nearing its end. My paper was read by title without my ever having read it over. In this way my stenographer's error escaped my notice. The galley proofs from the *Boston Journal* and from the transactions were gone over by the stenographer, and again the oversight was not detected.

Preparatory to moving, on October 1, my library and journals were packed in boxes the middle of September, and in this way the volume of the transactions, together with the *Boston Journal* and reprints were packed away for about five weeks awaiting the arrival of new book cases which were delayed in transit. In this way I had not had an opportunity to see the transactions or to look over the journal.

I first discovered the error last week, when my friend mentioned to me your communication in the *Atlanta Journal;* then I examined the copy of the transactions and hunted up the journal, and was horrified beyond description to find that you had not been given proper credit for paragraphs used. And, as stated before, I was about to write you when another friend apprised me of your communication in THE JOURNAL of the American Medical Association. I now hasten to make apologies for my seeming plagiarism.

I beg to offer herewith deposition from my stenographer covering this unfortunate occurrence, with my most profound regrets, and beg of you to accept my sincere apologies for my seeming imposition on you; and respectfully request you to make such retraction from your recent communication in THE JOURNAL of the American Medical Association, as your gentlemanly conscience may direct you, and to publish the same in next week's issue of THE JOURNAL of the American Medical Association.

Believing that a gentleman's honor, after proper explanations and apologies have been made, will not suffer at your hands, and thanking you in advance, permit me to remain,

Yours very fraternally,

W. E. FITCH, M.D.

[Accompanying the above letter was a deposition made by Dr. Fitch's stenographer corroborating the above and assuming all responsibility for the article.]

CHICAGO, Dec. 4, 1903.

Dr. W. E. Fitch:

Dear Sir:—I shall take great pleasure in publishing your letter and the attached affidavit. I will state that my critique was based, not only on the article in the *Annals of Pediatry and Gynecology*, but on a reprint *received from you* by one of my friends. I would suggest in passing that it is hardly fair to the profession for one to publish as original articles copied verbatim from text-books by an amanuensis. I would further remark that, in justice to yourself, you ought at least to look over the proofs of your articles or read them after they are printed and before sending out your reprints. I assure you, my dear sir, I do not feel that the matter under con-

sideration was so much a grievance to myself as a violation of a principle in which we are all interested. There is nothing in my critique which calls for correction or apology. The facts alleged are admitted by you, and nothing is now required further than the publication of your explanation of how it all happened. Very truly yours,

G. F. LYDSTON.

Good Men in Bad Company—An Explanation which Explains.

NEW YORK CITY, Dec. 3, 1903.

To the Editor:—My attention has been called to an advertising circular of the *Medical Brief* in which my name appears as a contributor. Will you kindly permit me to state through the columns of your widely-circulated journal that this article on "Fracture of the Radius" was not written for the *Medical Brief*. Some months ago a woman stenographer called at my office and represented that she was in great financial distress and asked me to dictate to her some short article for which she said she would be able to obtain $20 which was greatly needed at that time to prevent her from being turned out of her home by her landlord. She promised that the article should be offered to the *New York Medical Journal* or to the *Medical Record*, and if not accepted by them she would return it to me. Since that time I have not seen her or the article, nor did I know what had become of it until I saw it advertised as a contribution to the *Medical Brief*. I learn that she has imposed on the generosity of other members of the profession here in this city in like manner. JOHN A. WYETH.

[Does this explain why certain other reputable men appear as contributors to the above so-called medical journal, in some instances with photograph?—ED.]

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

A CRANIOTOMY, WAS IT JUSTIFIABLE?

———, WEST VIRGINIA, Nov. 27, 1903.

To the Editor:—I desire to report a case which was more than interesting to me, having practiced medicine less than three years, and one which required more than ordinary thought.

At 6 p. m., on November 4, I was called to Mrs. H., who had been in labor three or four hours, and made an examination, which revealed R. O. A. position, half-dollar dilatation, but no waters. The pains were sharp, cutting and irregular, pulse 82, temperature normal. After an hour the pains became more frequent and sharp, with no tendency to bearing down. She being a primipara, I suggested that she use all effort to expel contents and not cry aloud, gave 20 grains chloral and waited until 10:30, when I again examined and found dollar-size dilatation or more, but pains were yet sharp and cutting with only three or four minutes' interval—no waters yet formed. At 2 a. m. examination was again made and the membranes ruptured with less than a pint of water escaping. The pains soon became more severe and cutting, of a continuous character and very high up; after slight massage full dilatation was secured, but the head would not engage. It was then I had Dr X called in, who examined the patient and agreed with the above findings. Chloroform was at once administered and a high application of the forceps tried, but found to be impossible by either of us, even with external pressure from above. Another physician was called by the husband and he repeated the trial of high application, but failed. I then tried to do a podalic, but could never reach a foot, as did Drs. X and Y, who were also unable to accomplish anything. The woman was then growing cyanotic, with some hemorrhage going on all the time, so I decided to do a craniotomy, which was accomplished in a very few minutes at 5 a. m. The child was of medium size, weighing 8¾ pounds, and nothing out of the ordinary was discernible. The woman made an uneventful recovery and is now sitting up. Catheterization was necessary for two days after delivery.

Did the case justify operation? Being a young man in the field of medicine, I feel that older physicians should not hesitate to comment.

ANSWER.—We gladly publish the above report of a case, as requested, but omit name of reporter and place. As the reporter asks for comments we gladly give them.

The case well illustrates a mistake—we hope an uncommon one—of premature and unnecessary operative interference. While the average duration of labor in primiparæ is from 16 to 20 hours, a labor lasting 36 to 48 hours is not rare, and calls for no interference unless there is danger to the mother or to the child. So far as the report shows there was nothing abnormal in the labor up to 2 a. m., when the membranes were artificially ruptured. It was a mistake to urge the patient to bear down for the exercise of the voluntary muscles has little effect in dilating the uterus and needlessly wears out the patient. It would have been well to give the patient some relief from her suffering by administering some analgesic. The chloral was all right, but the dose was too small. Morphin would have been much more efficient. A hypodermic injection of ¼ grain would probably have given her some sleep and much relief. Although our correspondent does not describe the condition of the cervix when the membranes were ruptured, it is evident that dilatation was not completed, and the bleeding which occurred later during the manipulations was probably from tears in the cervix caused by the forceps or the efforts to turn. The artificial rupture was not indicated and was harmful. The application of the forceps to the head above the brim of the pelvis is always difficult and likely to be dangerous to both mother and child. It should never be attempted unless there is urgent indication. No indication was proved to exist in this case. Unless there was a contracted pelvis the head would probably have molded and descended in the course of a few hours. Finally, after the efforts to extract and turn had been in vain craniotomy was justifiable if the child was dead. Nothing is said on this point. We do not know that any effort was made to find the fetal heart beats. In case of failure to hear the fetal heart the death of the child should be determined by introducing the hand into the uterus and finding whether the cord beats or not. This case shows the importance of knowing the mechanism, progress and prognosis of spontaneous labor in its various manifestations in different individuals, and the danger of premature interference. It shows the importance of adhering strictly to the indications for interference, namely, danger to mother and child. It suggests the rule that when in doubt it is safer to rely on Nature than on interference.—ED.

HEISTER'S SURGERY.

FLAGSTAFF, ARIZ., Dec. 1, 1903.

To the Editor:—I have procured a copy of Heister's Surgery—English edition—a very novel old book, indeed, but, unfortunately, the title leaf is missing and I can not determine the year of publication. I am anxious to know in what year this book was printed and take the liberty of asking your assistance. The author was an operating surgeon as early as 1708. The text refers to events as late as 1736. The German edition must have been written after this. W. P. SIPE.

ANSWER.—The first English edition of this work was published by W. Innys, London, in 1743, from the Latin edition (2 vols., Venice, 1740). The fifth English edition appeared in 1753. All the English editions contained the two volumes in one; the first five editions were each composed of an introduction of XVI pages and two parts, of 476 and 338 pp. respectively, with 38 plates. The sixth and seventh editions were translated from Heister's later editions and appeared in 1757 and 1763; the sixth edition containing XVI, 456 and 404 pp. and 40 plates; the seventh (J. Clarke, London) XVI, 456 and 414 pp.

ANALYSIS OF MILK.

ST. LOUIS, Dec. 2, 1903.

To the Editor:—Will you give the name of some good book on the quantitative analysis of cow's milk and of condensed milk?

LEO C. HUELSMANN.

ANSWER.—Any one of the following we believe will be satisfactory: Outlines of Dairy Bacteriology, by H. L. Russell. Cloth, $1.00. Analysis of Milk and Milk Products, by H. Leffman. Cloth, $1.25. Air, Water and Food, by Richards and Woodmon. Cloth, $2.00. These books can be obtained of W. T. Keener & Co., Chicago; L. S. Mathews & Co., St. Louis; or any bookseller will order them.

TOOTH EXTRACTION IN PRESENCE OF ALVEOLAR ABSCESS WITH FISTULA.

———, WEST VIRGINIA, Dec. 2, 1903.

To the Editor:—1. Why is extraction of a tooth contraindicated when there is an alveolar abscess with fistula present? 2. When, in a case of this kind, could the tooth be extracted safely?

ANSWER.—1. It is not contraindicated. 2. A tooth of this kind may be extracted safely at any time.

Marriages.

THOMAS W. SHAW, M.D., Worcester, Mass., to Miss Diamond of Hartford, Conn.

WILLIAM KERR, M.D., to Miss Lula Dodd, both of Randolph, Iowa, November 18.

CHARLES D. RICKER, M.D., to Miss Lucretia B. Donavin at Baltimore, November 23.

DORSEY W. FELLERS, M.D., to Miss Grace Lecrone, both of Tiffin, Ohio, November 27.

HUGH TUDOR HALL, M.D., to Miss Anna Libbey Aldrich, both of Aiken, S. C., November 26.

GEORGE W. HEMMETER, M.D., to Miss Mae Elsie Thiemeyer, both of Baltimore, November 25.

JOHN HERMAN THESING, M.D., to Miss Catherine Wulftange, both of Cincinnati, November 18.

MCVEY BEATTY, M.D., Butler, Pa., to Miss Lavinia Virginia Blake, at Baltimore, November 26.

THOMAS B. MORRISSEY, M.D., to Miss Mary G. Hannegan, both of Portland, Me., November 11.

OTIS J. BALDWIN, M.D., Farmersville, Ill., to Miss Edith Austin of Virden, Ill., November 26.

CHARLES B. YOUNGER, M.D., Chicago, to Miss Nannie Ruth Broaddus of Lacon, Ill., November 25.

ROBERT MCDONALD SHANNON, M.D., to Miss Marie Gabriel Horton, both of Piqua, Ohio, November 26.

THOMAS H. RUCKER, M.D., Arlington, Ind., to Mrs. Josephine Lightner of New Albany, Ind., November 25.

CALEB D. THOMAS, M.D., Philadelphia, to Miss Mary E. Klotz of Lansford, Pa., in New York City, November 24.

WILLIAM L. VAN ORMER, M.D., Schellsburg, Pa., to Miss Sarah Bramwell Shafer, at Frostburg, Md., November 26.

JOHN W. WELLS, M.D., Taylorsville, Ky., to Mrs. Claudia Roby Bealer of Bardstown, Ky., at Louisville, November 25.

Deaths.

William Shaw Stewart, M.D. Jefferson Medical College, Philadelphia, 1863, assistant surgeon in the Federal Army during the Civil War; one of the founders of the Medico-Chirurgical College, for ten years its dean; and successively professor of obstetrics and clinical gynecology, and was professor emeritus at that institution; one of the founders of the American Academy of Medicine; for nine years director of public schools of Philadelphia; a member of the American Medical Association, Medical Society of the State of Pennsylvania, Philadelphia County Medical Society, and the Obstetrical Society of Philadelphia, died suddenly at his home in Philadelphia, November 25, from heart disease, aged 65.

Anthony F. Conroy, M.D. Jenner Medical College, Chicago, 1897, formerly of Chicago, died at the City Hospital, St. Paul, Minn., November 28, from tuberculosis contracted while a prisoner of the British at Pretoria, during the Boer War, aged 38. He was chief surgeon of the Red Cross corps of 150 surgeons and hospital attendants who went to South Africa with the avowed intent of caring for the Boer sick and wounded, but whose motives were impugned by the English.

Henry William Kendall, M.D. Medical College of Ohio, Cincinnati, 1853, one of the oldest physicians of Western Illinois; a member of the American Medical Association and Illinois State Medical Society; major-surgeon of the Fifteenth Illinois Volunteer Infantry and later chief surgeon second division, Sixteenth Army Corps in the Civil War, died at his home in Quincy, November 25, from peritonitis, after an illness of five days, aged 72.

William Millet Huntington, M.D. New York University, 1845, a member of the Vermont Medical Society, and first president of the White River Medical Society, who had practiced in Rochester, Vt., for more than 55 years, died at his home in that city, November 19, aged 84. He served during the Civil War as acting assistant surgeon in the Army, and represented his town in the General Assembly in 1863 and 1864.

Charles A. Dunham, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1880, in charge of the relief work following the fire which devastated Jacksonville, Fla., in 1901; major and surgeon Florida State Troops; surgeon of the First Florida Infantry, U. S. V., in the Spanish-American War, died suddenly from heart disease at his home in Jacksonville, November 22, aged 49.

Charles H. Porter, M.D. Albany (N. Y.) Medical College, 1861, assistant surgeon Sixth New York Volunteer Heavy Artillery throughout the Civil War, formerly a well-known physician of Albany, and for many years treasurer of the New York State Medical Society, died at Canandaigua, N. Y., November 21, after an illness of several years, aged 69.

William H. Jackson, M.D. University of South Carolina, Columbia, 1873, a member of the Erie County Medical Society, New York State Medical Association, American Medical Association, and New York and national associations of railway surgeons, died at his home in Springville, N. Y., from pneumonia, November 28, aged 62.

James R. McIlvain, M.D. Kansas City Medical College, 1882, a member of the American Medical Association, the first physician to locate in Oklahoma, and one of the best-known members of the fraternity in that territory, died at his home in Oklahoma City, November 26, after an illness of three weeks from heart disease, aged 50.

Charles J. Hagan, M.D. Starling Medical College, Columbus, 1864, who while still an undergraduate served as assistant surgeon in the Civil War, and after graduation as assistant surgeon in the Forty-sixth Ohio Volunteer Infantry, died at his home in Keokuk, Iowa, November 30, from dropsy, aged 61.

James A. Lane, M.D. Jefferson Medical College, Philadelphia, 1881, one of the early instructors in the Kansas City Medical College and once president of the Kansas State Medical Society, died at his rooms in Leavenworth, Kan., from tuberculosis, November 27, after an illness of more than a year, aged 50.

Cyrus Edson, M.D. College of Physicians and Surgeons, New York, 1881, for many years an efficient officer of the New York Board of Health, and ultimately health commissioner of the city, died at Roosevelt Hospital, New York, from pneumonia, December 2, after an illness of five days, aged 46.

Valentine S. Benson, M.D. Kentucky School of Medicine, Louisville, 1870, a member of the State Board of Equalization and for four years superintendent of the Illinois Hospital for the Criminal Insane, Chester, died at his home in McLeansboro, Ill., from heart disease, November 27, aged 69.

William J. Dupree, M.D. Vanderbilt University, Nashville, Tenn., 1876, of Westmoreland, Ala., a member of the American Medical Association, was found wandering a long distance from his home, November 26, was taken home, and died the same day without regaining consciousness, aged 48.

Clarence W. Lehman, M.D. Medical College of Ohio, Cincinnati, 1890, of Eaton, Ohio, a member of the American Medical Association and the Ohio State Medical Society, local surgeon for the Pennsylvania Railway, was killed in a collision of trolley cars, near Eaton, December 3.

Albert Blumberg, M.D. University of Würzburg, Germany, 1871, a member of the American Medical Association, a prominent physician of Pittsburg, Pa., was struck and instantly killed by a train at Braddock, Pa., where he had gone in consultation, December 1, aged 55.

Charles S. Boyce, M.D. Jefferson Medical College, Philadelphia, 1877, who was under sentence of imprisonment at Auburn Prison for criminal assault, but had been released on bail a few days before, died suddenly at his home in Salamanca, N. Y., November 19, from paralysis.

Joseph M. Harcourt, M.D. New York University, 1874, a graduate of Trinity College, Dublin, noted as a linguist, a mathematician and an orator, one of the most scholarly physicians of Brooklyn, died at his residence, November 30, after a lingering illness, aged 80.

Daniel James Neylan, M.D. New York University, 1886, at one time assistant surgeon in the Rhode Island Militia; a member of the American Electro-Therapeutic Association, died suddenly at his home in Bristol, R. I., November 26, from heart disease, aged 51.

William H. Holmes, M.D. College of Physicians and Surgeons, New York, 1857, assistant surgeon in the Navy during the Civil War, died at his home in Orange, N. J., November 30, from Bright's disease, after an illness of a year, aged 69.

Addison I. Cammack, M.D. New Orleans School of Medicine, 1866, a leading physician of Waco, Texas, and for many years a member of the local board of health, died at his home in that city, November 25, from rupture of an artery, aged 65.

John Fee, M.D. New York University, 1865, for 9 years city physician of Kansas City, Mo., for several years a surgeon in the Army, died suddenly at his home in Kansas City, from pulmonary edema, November 30, aged 67.

George B. Acker, Jr., M.D. Western Pennsylvania Medical College, Pittsburg, 1897, of Lawrenceville, Pa., died at the home of his parents in Pittsburg, December 1, from pneumonia, after an illness of four days, aged 35.

John McKinnon, M.D., professor of diseases of the kidneys and clinical medicine in the Bennett College of Eclectic Medi-

cine and Surgery, Chicago, died at his home from fatty degeneration of the heart, November 30.

Thomas Fitzhugh Grayson, M.D. University of Pennsylvania, Philadelphia, 1866, the pioneer practitioner of Fort Dodge, Iowa, died at his home in that city, November 22, from gastric trouble of long standing, aged 65.

James R. Adams, M.D. Medical College of Ohio, Cincinnati, 1852, surgeon of the Forty-eighth Indiana Volunteer Infantry during the Civil War, died at his home in Petersburg, Ind., November 29, aged 83.

Nathan H. Brown, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1875, was stricken by apoplexy at his home in Fremont, Neb., November 28, died early the next morning, aged 51.

Henry H. W. Crittenden, M.D. Washington University School of Medicine, Baltimore, 1867, died at his home in Crewe, Va., November 30, from paralysis, after an illness of two weeks, aged 59.

Thomas Richardson Storer, M.D. Jefferson Medical College, Philadelphia, died at his home on Scenery Hill, near Washington, Pa., November 25, after an illness of two months, aged 61.

Wallace O. Buckland, M.D. St. Louis Eclectic Medical College, 1881, died at his home in Oakland, Cal., from postoperative pneumonia, November 28, after an illness of one week, aged 65.

George P. Campbell, M.D. Bellevue Hospital Medical College, New York, 1870, died suddenly at the foot of his office stairs in Wauseon, Ohio, from apoplexy, November 25, aged 55.

Frank R. Payne, M.D. Western Reserve University, Cleveland, 1889, died at his home in Cleveland, from pneumonia, November 23, after an illness of eight days, aged 37.

James R. Cromer, M.D. Eclectic Medical Institute, Cincinnati, 1874, a retired physician of Flora, Ind., died at his home in that place, December 2, from pneumonia, aged 65.

William G. Saunders, M.D., city physician of Grand Rapids, Mich., about thirty years, ago, died at Butterworth Hospital in that city, November 26, from apoplexy, aged 76.

Michael Heinimann, M.D., a "Forty-niner," who practiced medicine in San Francisco for more than half a century, died at his home in Oakland, November 26, aged 85.

Albert G. Beebe, M.D. Hahnemann Medical College, Chicago, 1869, died at his home in Chicago, December 2, from heart disease, after an illness of four days, aged 60.

J. Franklin Merkle, M.D. University of Pennsylvania, Philadelphia, 1894, died at his home in Perkasie, Pa., November 26, after an illness of several weeks, aged 42.

Welford S. Fisher, M.D. University of Michigan, Ann Arbor, 1903, an interne at the University Hospital, died in that institution, November 30, from typhoid fever.

Thomas S. Freeman, M.D., for more than thirty years a practitioner of Sherman, Texas, died suddenly from heart disease at his home, November 23, aged 76.

Gracia Leah Morehead, M.D. Woman's Medical College, Kansas City, Mo., 1901, died from heart disease at her home in Milwaukee, Wis., December 2, aged 25.

Francis Asbury Pinckard, M.D. University of Maryland, died from paralysis at his home in Pinckardsville, Va., November 30, after an illness of three days, aged 59.

Thomas H. Armstrong, M.D. Starling Medical College, Columbus, 1855, of Woodsfield, Ohio, died at the home of his son in Bellaire, Ohio, November 18.

Andrew J. Comstock, Jr., M.D. Jefferson Medical College, Philadelphia, 1884, died at his home in Ventura, Cal., November 21, after a long illness.

Douglas P. Beatty, M.D. New York University, 1857, formerly of Hull, Ala., was found dead at his home near Kennesaw, Ga., November 26.

David S. Oliphant, M.D. Homeopathic Medical College of Missouri, St. Louis, 1861, died at his home in Toronto, Ont., November 13, aged 87.

Hugh C. Murphy, M.D., died at his home in Kansas City, Mo., November 25, from Bright's disease, after an illness of three weeks, aged 60.

Benjamin N. Ogden, M.D. University of Louisville, 1886, of Oak Hill, W. Va., was found dead in bed at Charleston, W. Va., November 27.

Joshua Warner, M.D., the pioneer physician of Westburg Township, Que., died at his home in East Angus, November 22, aged 80.

Overton Carr Todd, M.D. St. Louis Medical College, 1874, died at his home in Powell, Texas, November 27, from neuralgia of the heart.

Silas W. Kellar, M.D. Western Reserve University, Cleveland, 1885, died at his home in New Kensington, Pa., November 27, aged 45.

Fred Welch, M.D. Dartmouth Medical College, Hanover, N. H., 1894, of Centre Strafford, N. H., died in Montrose, Colo., November 16.

Joseph M. Loop, M.D. University of Michigan, Ann Arbor, 1855, died at his home in Port Sanilac, Mich., recently, aged 93.

Joseph H. Maynard-Bellerose, M.D. University of Vermont, Burlington, died at his home in that city, November 25, aged 39.

D. D. Robertson, M.D. University of Louisville, 1867, died at his home in Calhoun, Ky., November 16, from hepatitis, aged 67.

J. M. Burt, M.D., for ten years coroner of Clarke County, Wash., died at his home in Vancouver, November 11, aged 72.

Andrew J. Salts, M.D., health officer of Corning, Iowa, for several years, died at his home in that city, November 23.

Ralph L. Graves, M.D., a veteran of the Mexican War, died at his home in San Antonio, Texas, November 29, aged 85.

H. L. Stewart, M.D., 1878, died at his home in Humboldt, Ill., November 24, after a long illness, aged 80.

Thomas Hillery Taylor, M.D., of Marshall, Texas, died in that place, November 20, aged 77.

J. Frank Carder, M.D., died at Salem, W. Va., December 1, aged 81.

Deaths Abroad.

Dr. F. Brun, professor agrégé at Paris, and one of the eight co-editors of the *Presse Médicale*, died at Paris, November 10, aged 49. He had made a specialty of surgery for children and had been a prolific writer on this and other subjects. One of his latest works was on the malignant tumors of the kidney in children. He devoted himself to ophthalmology at first, and published a valuable text book on "Therapeutique oculaire." He succumbed to the progress of a neurasthenic trouble.

Dr. A. A. Proust, the well-known French authority on international hygiene, died at Paris, November 26, aged 69. He has been inspector general of the French sanitary service since 1884, and has published numerous works on public and private as well as international hygiene, and on other matters connected with the public health.

Book Notice.

A TEXT-BOOK OF THE SCIENCE AND ART OF OBSTETRICS. By Henry J. Garrigues, A.M., M.D., Consulting Obstetric Surgeon to the New York Maternity Hospital. With 504 Illustrations. Cloth. Pp. 844. Price, $5.00. Philadelphia and London: J. P. Lippincott Co. 1902.

This is a companion work to the author's "Text-Book on Gynecology." It is a practical contribution to the literature, and conforms to the high standard of the volume of gynecology. The sections dealing with the development of the ovum, the maternal changes incident to pregnancy, the anatomy of pregnancy, labor and the puerperium are commensurate with the needs of a text-book for the student, and the subjects are adequately stated. The general instructions in the technic of operations, i. e., the treatment of brow, face, occiput posterior, etc., are elucidated after the manner of most books on obstetrics—too much is left to the interpretation of the reader; the steps are insufficiently stated. This is a common fault and can not be held specifically against the work before us. Exception may well be taken to certain statements and directions which are not in consonance with recent opinion. The recommendation that vaginal examinations "should only be repeated with one or two hour interval" does not keep in accord with the necessities of an aseptic conduct of labor; after one thorough *diagnostic* examination in labor little can be learned by vaginal exploration which can not be equally elicited by the deportment of the patient and external palpation. In the delivery of the head the slovenly method of Ritgen-Goodell is recommended—of pulling the face down with the finger in the rectum; other methods of enucleating the head not antagonistic to asepsis would meet indications better. With the same tenacity which governs so many obstetric writers, Dr. Garrigues persists in

associating Credé's method of conducting the third stage with what should be described as a physiologic method; "Credé" distinctly is a procedure for a pathologic third stage. The absence of illustrations and detailed description of Mauriceau's (so-called Smellie-Veit) method neglects the most certain, most powerful, least injurious to the child, and most rational delivery of the after-coming head by manual means—in no respect can the Prague or Smellie methods compare to the former. It is a distinct novelty to see an authority of the present time recommending ferric chlorid solutions in a douche or tampon for hemorrhages in placenta previa and postpartum, as their proven dangers far outweigh their slight temporary advantage. The advocacy of the serre-fine for the repair of perineal laceration can not be too strongly condemned; as far as we know these little instruments have been relegated to the museum as they can not compare in effectiveness with properly inserted sutures. The illustrations are in general accurate and depict the essential points of the book—some are new, most, however, are the approved cuts of other works; certain cuts, as in the chapter on the conduct of normal labor, might well be substituted by more approved drawings.

State Boards of Registration.

COMING EXAMINATIONS.

Missouri State Board of Health, Southern Hotel, St. Louis, Dec. 14-16. Secretary, Dr. W. F. Morrow, Kansas City.

Medical Council, Philadelphia, Dec. 15. Secretary, Dr. Isaac B. Brown, Harrisburg.

Medical Examining Board of Virginia, Lynchburg, Dec. 15-18. Secretary, Dr. R. S. Martin, Stuart.

Colorado State Board of Medical Examiners, 1723 Tremont St., Denver, Dec. 22-24. Secretary, Dr. S. D. Van Meter, Denver.

Utah State Board of Medical Examiners, Salt Lake City, Jan. 4, 1904. Secretary, Dr. R. W. Fisher, Salt Lake City.

State Medical Examining Board of Washington, Tacoma, Jan. 5-6, 1904. Secretary, Dr. P. B. Swearingen, Tacoma.

Board of Medical Examiners of Arizona, Phoenix, Jan. 4-5, 1904. Secretary, Dr. Wm. Duffield, Phoenix.

State Medical Examining Board of North Dakota, Grand Forks, Jan. 5, 1904. Secretary, Dr. H. M. Wheeler, Grand Forks.

Board of Medical Examiners of the State of Oregon, Portland, Jan. 5, 1904. Secretary, Dr. Byron E. Miller, Portland.

Colorado State Board of Medical Examiners, 1723 Tremont St., Denver, Jan. 5-6, 1904. Secretary, Dr. S. D. Van Meter, Denver.

Minnesota State Board of Medical Examiners, State Capitol Bldg., St. Paul, Jan. 5-7, 1904. Secretary, Dr. C. J. Ringnell, Minneapolis.

State Board of Health of Rhode Island, State House, Providence, Jan. 7, 1904. Secretary, Dr. G. T. Swarts, Providence.

Indiana State Board of Medical Registration and Examination, Indianapolis, Jan. 13, 1904. Secretary, Dr. W. T. Gott, Crawfordsville.

Board of Medical Examiners of South Dakota, Cataract Hotel, Sioux Falls, Jan. 13-15, 1904. Secretary, Dr. H. E. McNutt, Aberdeen.

Wisconsin Board of Medical Examiners, Milwaukee, Jan. 12, 1904. Secretary, Dr. F. R. Forsbeck, Milwaukee.

Vermont State Board of Medical Censors, Y. M. C. A. Bldg., Burlington, Jan. 13-14, 1904. Secretary, Dr. S. W. Hammond, Rutland.

Board of Medical Supervisors of the District of Columbia, Washington, Jan. 14, 1904. Secretary, Dr. Wm. C. Woodward, Washington.

Illinois State Board of Health, Great Northern Hotel, Chicago, Jan. 14-16, 1904. Secretary, Dr. J. A. Egan, Springfield.

Iowa State Board of Medical Examiners, Capitol Bldg., Des Moines, Jan. 26-27, 1904. Secretary, Dr. J. F. Kennedy, Des Moines.

Vermont Report.—Dr. W. S. Hammond, secretary of the Vermont State Board Medical Censors (Regular), reports the written examination held at Burlington, July 8-9, 1903, as follows: Number of subjects, 8; questions, 80; percentage, 70; candidates, 23; passed 20; failed, 2. Following are the colleges of the candidates, the years of graduation, the grades attained and the questions asked:

PASSED.

University of Vermont, (1887) 80; (1903) 78, 72, 79, 79, 78, 74. 80, 81, 78, 78,* 80.
Baltimore Medical College, (1903) 76, 71, 70, 79.

Tufts Medical College	(1903)	81
Detroit College of Medicine	(1900)	70
Columbia University, New York	(1903)	79
Bellevue Hospital Medical College	(1894)	70
New York City University	(1903)	77

FAILED.

Baltimore Medical College	(1902)	58
Maryland Medical College	(1903)	58

* This candidate did not take the whole examination; his average is given as 78 for the subjects covered.

PHYSIOLOGY.

1. Give the essential difference between cow's milk and human milk. 2. Describe: (*a*) striated muscle fiber; (*b*) unstriated muscle fiber; (*c*) give an example of each. 3. Describe the fetal circulation. What changes occur in it after birth? 4. Give the physical characters and composition of normal urine. 5. Trace the products of digestion from the intestinal villi to the blood stream. 6. (*a*) Explain the difference between afferent and efferent nerves. (*b*) What is the function of the column of Goll and what is its situation in the cord? 7. Locate the following brain centers: Leg, arm, face, speech. 8. Give the histology of the liver. 9. Name five digestive fluids and give the reaction of each. 10. Give the functions of the vasomotor nervous system.

CHEMISTRY.

1. Give formula for converting F. theometric reading to C. scale. 2. What is understood by electrolysis? 3. What are radicals as used in chemical formulas? Illustrate. 4. Give briefly the chemistry of 1. 5. Why is calomel contraindicated in a case taking a solution of KI? 6. How would you conduct an autopsy and care for removed organs in a case of suspected arsenical poisoning? 7. What are the principal products of petroleum distillation? 8. Name all the causes of a turbid urine freshly passed. 9. Give a test for bile in the urine. 10. What may high and low sp. gr. in urine indicate?

PATHOLOGY.

1. Give pathology and prognosis for internal otitis following scarlatina. 2. Specify the dangers to be feared in deep cuts of the palm of the hand. 3. What conditions would influence you for, and what against, conservation in a deep buzzsaw cut of the wrist? 4. Give the symptoms, ordinary complications and prognosis in backward dislocations of the ulna on the humerus. 5. Describe the symptoms, pathology and prognosis of empyema and differential diagnosis from ordinary serous pleurisy. 6. Give the symptoms of strangulated inguinal hernia. 7. How would you distinguish between suppression, nervous retention, stricture and enlarged prostate in a person unable to urinate? 8. Give description, etiology and pathology of housemaid's knee. 9. Give the symptoms in fracture of the middle of the fibula. 10. Describe a bunion, giving its etiology and pathology.

SURGERY.

1. If a patient with chronic otorrhea and painful swelling behind the ear had a chill, vomiting, headache, slow pulse, trembling, convulsions or paralysis, what would you suspect and what treatment would you advise? 2. If you found a man at night in a mountain camp, nearly exsanguinated by the hemorrhage from a deep cut in the palm of the hand, what would you do if you had no light but a single tallow dip, no instruments but those in your pocket case and no surgical aid within twenty miles? 3. What would you do for a man who had all the flexor tendons, radial and ulnar arteries and both bones of the fore arm cut off close to the wrist by a buzzsaw, there still being circulation enough to keep the hand warm? 4. How would you treat a backward dislocation of the ulna on the humerus? 5. How would you treat an empyema? 6. What would you do for an old reducible inguinal hernia which has become strangulated? 7. What would you do for a man of 75 who was unable to urinate? 8. Give treatment for housemaid's knee. 9. How would you treat a compound fracture of the tibia and fibula? 10. How would you treat a patient crippled by an intractable bunion?

ANATOMY.

1. Briefly describe the internal hearing apparatus. 2. Describe the circulation in the hand. 3. Give the surgical anatomy of the wrist. 4. Give the surgical anatomy of the elbow. 5. Describe the gross anatomy and boundaries of the cavity of the chest. 6. Give the anatomy of oblique inguinal hernia. 7. Give the gross anatomy of the bladder and male urethra. 8. Give the anatomy of the knee joint. 9. Give the surgical anatomy of the leg. 10. Give the surgical anatomy of the great toe.

PRACTICE.

1. What do you understand by the terms: Symptoms, diagnosis, prognosis, period of incubation of diseases? 2. Differentiate between rubeola and rubella. Give treatment of rubeola and name its complications. 3. What are the symptoms, prognosis and sequelæ of cerebral hemorrhage? 4. Describe sonorous sibilant, crepitant and mucous râles. 5. Give the rules for the conduction of an autopsy when poison is suspected. 6. What symptoms may arise from a dislocated kidney? 7. Name the diseases with which gallstone colic may be confounded and give differential diagnosis. 8. Give the varieties of erysipelas, diagnosis and treatment. 9. Name five diseases in which Cheyne-Stokes respiration is commonly found. 10. What are the symptoms, prognosis and treatment of hysteria?

MATERIA MEDICA AND THERAPEUTICS.

1. Define the term narcotic, hypnotic, anesthetic, antispasmodic, with illustrations of each group. 2. Name the principal therapeutic uses of belladonna. 3. What is asafetida, its preparations and therapeutics? 4. Name the principal simple purgatives with their preparations and doses. 5. Give the symptoms and treatment of chloral hydrate poisoning. 6. Name the preparations of bromids and give their therapeutics. 7. What are the uses of veratrum viride? How would you treat a case of veratrum poisoning? 8. Give doses of tincture aconite, opium, gentian, uva ursi, chlorid of iron, gelsemium, guaiac, ipecac and wine of colchicum. 9. Name three diuretics and give their therapeutic use. 10. Write two prescriptions for use in the summer diarrhea of children.

OBSTETRICS.

1. What are the signs of pregnancy and how are they classified? 2. What are the causes, dangers, symptoms and treatment of abor-

tion. 3. What is the vomiting of pregnancy, and how should it be treated. What should be learned at the first examination in a case of labor? 4. How should a case of breech presentation be managed throughout? 6. To what is rigidity of the os due, and what is the treatment? 7. What is the treatment of placenta previa when occurring before full term, and its management at full term? 8. Give cause and treatment of secondary umbilical hemorrhage in the new-born child. 9. Give the causes, symptoms and management as best understood and practiced at present of albuminuria of pregnancy. 10. State the causes, symptoms and treatment of puerperal phlebitis.

Association News.

List of new members for the month of November, 1903:

ALABAMA.

McLester, Jas. S., Birmingham.
Ferrell, J. H., Woodlawn.
Clark, N. G., Ensley.
Watson, B. Walne, New Decatur.
Hill, Robt. S., Montgomery.
Hartung, G., Cullman.
Palmer, R. D., Carson.
Rosamond, W. L., Ensley.
Edwards, J. H., Wylam.
Horton, J. J., New Market.
Gordon, S. A., Collirene.

ARKANSAS.

Ward, O. D., Tucker.
Deaderick, W. H., Marianna.

CALIFORNIA.

Pillsbury, E. S., Los Angeles.
Gunn, Herbert, San Francisco.
Abraham, Henry, San Francisco.

CONNECTICUT.

Seaver, Jay W., New Haven.
Boucher, John B., Hartford.
Loveland, John E., Middletown.

FLORIDA.

Conter, A. E., Lamont.

GEORGIA.

Williams, V. G., Chipley.

ILLINOIS.

Sauer, H. Edward, Chicago.
Derdiger, A. L., Chicago.
Mitchell, T. B., Chicago.
Pratt, Irene R., Chicago.
Davidson, Frank S., Chicago.
Smith, Jos. F., Chicago.
Collins, L. C., Chicago.
Smith, G. R., Bloomington.
Ward, Milan T., Toulon.
Gerzema, Franz, Peoria.
Bowling, J. Wm., Shawneetown.
Shastid, Thos. W., Pittsfield.
Parker, E. S., Vermont.
Brooks, E. W., St. Elmo.
Crane, Wm. W., Sinclair.
Golding, Daniel G., Arrowsmith.
Taft-Grimes, Ellen F., Decatur.
Watkins, Henry T., Olney.
Maloney, L. H., Savanna.
Moore, Samuel, Danville.

INDIANA.

Dorsey, Frank O., Indianapolis.
Zaring, C. T., Greencastle.

IOWA.

Whiteis, Wm. R., Iowa City.
Judkins, Oliver P., Indianola.
Tobey, Samuel D., Oakland.
Casey, J. M., Ft. Madison.
Busby, Chas. D., Brooklyn.

KENTUCKY.

Harthill, Eleanor A., Louisville.
Bushong, Geo. W., Tompkinsville.
Palmore, E. E., Strode.
Calvert, Caleb A., Fountain Run.
Bedford, T. H., Meshack.
Sabel, Stanley O., Bowling Green.
Yates, J. A., Edmonton.
Wagoner, A. L., Scottsville.
Talbott, John G., Burkesville.
Sympson, W. A., Centre Point.
Duncan, R. F., Tompkinsville.
Garnett, R. E., Glasgow.
Taylor, J. M., Glasgow.

MARYLAND.

Talbott, Thos. J., Baltimore.

MASSACHUSETTS.

Foster, H. K., Peabody.
Rose, W. H., Worcester.

MICHIGAN.

McMeekin, R. J., Saginaw.
Gratton, Jos. H., Detroit.
Fritch, G. A., Detroit.
Brown, F. W., Grand Rapids.

The Public Service.

Army Changes.

Memorandum of changes of stations and duties of medical officers, week ending Dec. 5, 1903:

Shaw, Herbert G., asst.-surgeon, relieved from duty at Fort Miley, Cal., and ordered to Manila, P. I.

Bushnell, Geo. E., surgeon, leave of absence extended for twenty-three days.

Ekwurzel, Geo. M., asst.-surgeon, granted fourteen days' leave of absence.

Marrow, Charles E., asst.-surgeon, granted fifteen days' leave of absence, to take effect on completion for examination for promotion.

Reynolds, F. P., asst.-surgeon, in addition to his present duties at the U. S. General Hospital, Washington Barracks, will report in person to Colonel Charles L. Heizman, asst.-surgeon general, president of the faculty of the Army Medical School at Washington, D. C., for duty as instructor in hospital corps drill and assistant instructor in duties of medical officers and medical department administration.

Ekwurzel, Geo. M., asst.-surgeon, assigned to duty at Fort Banks, Mass., having been relieved from further duty in the Division of the Philippines.

Cox, Walter, asst.-surgeon, relieved from duty at Fort Banks, Mass., and ordered to Fort Reno, O. T.

Farr, Charles W., asst.-surgeon, relieved from duty at Fort Reno, O. T., and ordered to Fort Mason, Cal.

Appel, Aaron H., surgeon, sick leave further extended two months.

Kendall, Wm. P., surgeon, ordered to accompany insane from Presidio of San Francisco to Government Hospital for the Insane, Washington, D. C.

Keller, Wm. L., asst.-surgeon, relieved from further duty in the Division of the Philippines and ordered to Fort Riley, Kan.

Brechemin, Louis, surgeon, leaves Ord Barracks, Cal., en route to take charge of Medical Supply Depot, San Francisco.

Ives, Frank J., surgeon, reports on twenty-one days' leave from San Francisco.

Rockhill, E. P., asst.-surgeon, granted thirty days' leave of absence.

Howard, Dean C., asst.-surgeon, detailed to represent Medical Department of the Army at meeting of the American Roentgen Ray Society, to be held at University of Pennsylvania, Philadelphia, Dec. 9 and 10, 1903.

Burr, Rollin T., contract surgeon, relieved from duty at Cabana Barracks, Havana, Cuba, and is en route to his new station, Fort Rodman, Mass.

Amador, Raoul A., contract surgeon, on one month's leave of absence from Fort Revere, Mass.

Stockard, James K., contract surgeon, granted one month's leave of absence on account of sickness, at the expiration of his ordinary leave.

Navy Changes.

Changes in the medical corps of the U. S. Navy for the week ending Nov. 28, 1903:

Alfred, A. R., surgeon, commissioned surgeon, with rank of lieutenant, from Jan. 4, 1903.

Noyes, E. R., pharmacist, warranted pharmacist from Oct. 20, 1903.

Grunwell, A. G., surgeon, detached from the Naval Hospital, Washington, D. C., and ordered to the *Minneapolis*.

Carpenter, D. N., surgeon, ordered to the Naval Hospital, Navy Yard, Washington, D. C.

Noyes, E. R., pharmacist, ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C.

Marine-Hospital Service.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Dec. 5, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, Nov. 21-28, 6 cases.
California: Los Angeles, Nov. 14-21, 1 death.
Illinois: Chicago, Nov. 21-28, 3 cases.
Louisiana: New Orleans, Nov. 21-28, 2 cases imported.
Massachusetts: Nov. 21-28, Haverhill, 1 case; Lowell, 1 case.
Michigan: Detroit, Nov. 21-28, 1 case.
New Hampshire, Manchester, Nov. 21-28, 2 cases.
New Jersey: Camden, Nov. 21-28, 1 case.
Ohio: Nov. 21-28, Cincinnati, 2 cases; Youngstown, 9 cases.
Pennsylvania: Nov. 21-28, Johnstown, 6 cases, 1 death; Philadelphia, 70 cases, 11 deaths; Pittsburg, 25 cases, 7 deaths, imported 2; Reading, Nov. 23-30, 3 cases.
Tennessee: Memphis, Nov. 21-28, 8 cases.

SMALLPOX—FOREIGN.

Ecuador: Guayaquil, Nov. 7-14, 1 death.
Great Britain: Nov. 7-14, London, 16 cases; Newcastle-on-Tyne, 18 cases; Nottingham, 4 cases.
Italy: Catania, Nov. 6-12, 1 death; Palermo, Nov. 7-14, 1 case.
Russia: Moscow, Oct. 31-Nov. 7, 1 case.
Turkey: Smyrna, Nov. 1-8, 16 deaths.

YELLOW FEVER—UNITED STATES.

Texas: Cannel, Nov. 26, 4 cases; Nov. 23-Dec. 1, Laredo, 6 cases, 5 deaths; San Antonio, 5 cases, 5 deaths; Minera, Nov. 28, 2 cases, 1 death.

YELLOW FEVER—FOREIGN.

Mexico: Nov. 8-14, Ciudad Victoria, 9 cases, 7 deaths; Linares, 74 cases, 6 deaths; Merida, 3 cases; Nuevo Laredo, 2 deaths; Menciova, Nov. 17-18, 2 cases, 2 deaths; Reata, Nov. 26, 1 case; Vera Cruz, Nov. 15-28, 14 cases, 9 deaths.

CHOLERA—FOREIGN.

Turkey: Syria, Nov. 7, prevailing.

PLAGUE—UNITED STATES.

California: San Francisco, Nov. 12, 1 case, 1 death.

PLAGUE—FOREIGN.

Egypt: Oct. 24-31, Alexandria, 3 cases, 2 deaths; Summalut District, 2 cases.
India: Bombay, Oct. 26-Nov. 3, 45 deaths; Karachi, Oct. 18-Nov. 1, 28 cases, 25 deaths.
Japan: Yokohama, Oct. 24-31, 1 case, 1 death.
Mauritius: Oct. 19-26, 117 cases, 55 deaths.

Medical Organization.

Indiana.

ELEVENTH COUNCILOR DISTRICT FULLY ORGANIZED.—All the counties constituting the Eleventh Indiana Councilor District have been reorganized, each society has adopted the new constitution and by-laws, and some of them report a large increase in membership. The councilor of the district, Dr. Robert Hessler of Logansport is urging the adoption of a regular program for the meetings, made out for a year in advance, if possible. Such a program stimulates the writer of a paper, and, on the other hand, good papers bring out a good attendance.

Iowa.

HARDIN COUNTY MEDICAL SOCIETY.—This society was organized a few days ago with the following officers: Dr. William P. Burke, Iowa Falls, president; Dr. Walter H. Lewis, Alden, vice-president, and Dr. William E. Whitney, Eldora, secretary.

Minnesota.

CHISAGO-PINE COUNTY MEDICAL SOCIETY.—Dr. W. S. Fullerton, St. Paul, state organizer of the Minnesota State Medical Society, reports the organization of this society on the standard plan, November 17, with the following officers: President, Dr. Horace G. Murdock, Taylor's Falls, Chisago County; vice-president, Dr. A. J. Stowe, Rush City, Chisago County; secretary, Dr. Olof S. Werner, Lindstrom, Chisago County; treasurer, Dr. Christopher A. Anderson, Rush City, Chisago County; delegate, Dr. Carl O. Hertzman, Lindstrom, Chisago County, and censors, Drs. Duke W. Cowan, Sandstone, Pine County; C. E. Lundgren, North Branch, Chisago County, and Edwin A. Riley, Willow River, Pine County.

Nebraska.

RICHARDSON COUNTY MEDICAL SOCIETY.—At the meeting of this society, November 25, in Falls City, Dr. John W. Bullard, Pawnee City, councilor for the third district, addressed the meeting, explaining the advantages of the standard plan of organization and urging its adoption. He was given close attention, and the society will take action on the matter at its next meeting, December 30.

Pennsylvania.

NORTHUMBERLAND COUNTY MEDICAL ASSOCIATION.—On November 27, physicians of the county met at Sunbury and organized a Society with the following officers: President, Dr. William B. Stoner, Sunbury; vice-presidents, Drs. Frederick D. Raker, Shamokin, and Ellis A. Smith, Snydertown; secretary, treasurer and reporter, Dr. Horatio W. Gass, Sunbury, and censors, Drs. John H. Vastine, Shamokin, Sidney Davis, Milton, and J. Kerchner, Georgetown.

South Dakota.

SOUTH DAKOTA (FIFTH DISTRICT) MEDICAL SOCIETY.—In accordance with the standard plan of organization, this society was organized at Madison, November 24, Dr. Arthur J. Doty, Colman, councilor for the Fifth District, was elected president; Dr. Frederick H. Files, Madison, vice-president, and Dr. John M. Duff, Madison, secretary and treasurer. The territory of the society has Madison as a center and extends east to Egan, west to Artesian, and north to Oldham.

Texas.

FALLS COUNTY MEDICAL SOCIETY.—Physicians of Falls County met at Marlin, November 25, and organized a society with an initial membership of 18, and elected the following officers: Dr. James P. Barton, Mooreville, president; Dr. Walter H. Allen, Marlin, vice-president, and Dr. Burr G. Ward, Marlin, secretary.

Society Proceedings.

COMING MEETINGS.

Southern Surgical and Gynecological Association, Atlanta, Ga., Dec. 15-17.
Western Surgical and Gynecological Association, Denver, Dec. 28-29.

NEW YORK ACADEMY OF MEDICINE.

Regular Meeting of the Section on Obstetrics and Gynecology, held Nov. 27, 1903.

L. J. Ladinski, M.D., Chairman.

Toxemia of Pregnancy.

DR. WILLIAM S. STONE, in this paper, said that there was frequently present an increased irritability of the medullary centers, dependent on the presence of toxins in the blood. In reporting his own cases, the speaker said that in one of the cases the vomitus contained bile, blood and epithelial cells from the stomach—in short, corresponded to "black vomit." In another case, in which the urine contained many casts and much albumin, the patient's condition was aggravated by emptying the uterus, and death in coma occurred in forty-eight hours. A complete autopsy was made in this instance, apparently only the second one on record, and it pointed very strongly, as did the clinical course, to acute yellow atrophy of the liver. It was pointed out that eclampsia occurred in one-tenth of the cases without albuminuria, and that the renal lesions varied from those of ordinary nephritis to degenerations like those found in the liver. The latter organ might show chronic congestion or the changes observed in acute yellow atrophy. In all cases the renal lesions appeared to be less severe, and secondary to those of the liver. The kidney was often normal, but a diseased kidney and a normal liver were never observed in these cases. Although slight albuminuria was probably always present, it was chiefly significant when noted in the early months of pregnancy. The presence of blood, casts, leucin, tyrosin and bile in the urine was of great importance. In the treatment, the chief reliance should be on the use of saline solution per rectum, or, in some cases, on hypodermoclysis or saline infusion. The induction of premature labor often served to precipitate the fatal issue, but this measure should be undertaken, if possible, before the onset of black vomit.

DISCUSSION.

DR. CHARLES JEWETT said that a patient was never safe while albuminuria existed. The quantity of urea excreted was, in his opinion, a greatly overrated danger-signal, for it not only varied widely within the limits of safety, but fluctuated with the quantity of nitrogenous food ingested, and was normally less in the later months of pregnancy. He

had frequently seen women pass safely through labor, though they were excreting a very small quantity of urea.

Dr. S. Marx thought antecedent gastric disorders played an important part in connection with hyperemesis gravidarum. He kept such patients quietly in bed on a fluid diet and gave them tablespoonful doses of bismuth. Experience had taught him to think less and less of albuminuria and more and more of the quantity of urea excreted as an index of danger, although he did not mean to imply by this statement that the urea itself was necessarily the element of danger in the toxemia of pregnancy. He had never seen a case of eclampsia in which the urea was not diminished, although it was true he had seen patients escape eclampsia who were excreting very little urea.

Dr. E. B. Cragin favored the theory of the hepatic origin, but many pelvic disorders cause nausea and vomiting in the non-pregnant; moreover, if all the early cases of vomiting were the result of toxemia he could not understand why this vomiting should so commonly cease spontaneously later when the products of the fetus tended to increase the toxemia. Four recent cases of toxemia of pregnancy dying in hospital were reported by the pathologist to be suffering from acute yellow atrophy of the liver. The general line of treatment advised in the paper met with his hearty approval, but he would emphasize the need of promptly emptying the uterus, for, although this procedure did seem to hasten the fatal termination in some cases, it was not infrequently followed by immediate improvement in seemingly very severe cases. Albuminuria should always be looked on as a danger signal.

Dr. S. W. Bandler expressed the opinion that the toxins were given off by the placenta. If such marked results can follow changes in the thyroid or other well-known internal secretions, it is reasonable that they may follow increase or diminution of the placenta secretion.

Therapeutics.

[Our readers are invited to send favorite prescriptions—such as have been tried and found useful—for publication in these columns. In each case the name of the sender must accompany the prescription, but the name will be published or omitted, as the sender may prefer.]

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Some of the New Remedies in the Oculist's Practice.

L. Konigstein, in *Annals of Ophthal.*, states that formerly ophthalmic medication consisted mainly in the use of atropin, silver nitrate and mercury. Atropin was most frequently used and was a very much-abused drug. Silver nitrate was also used indiscriminately in all inflammatory conditions of the conjunctiva and likewise increased the sufferings of the patient. Iodin was employed frequently as a substitute for mercury. Among the newer remedies he mentions the following indications for their employment: 1, as anesthetics; 2, as analgesics; 3, as mydriatics for ophthalmoscopic examinations; 4, as cosmetics; 5, as an irritant in paresis of the sympathetic; 6, as an anemic agent. He employs cocain, at present, as a substitute for general narcosis, even using it in enucleation of the eye bulb combined with adrenalin. To produce an analgesic effect deep in the eye bulb, he uses aconin and dionin. In glaucoma he combines eserin with cocain as an analgesic agent.

Adrenalin is another important adjunct to the remedies for its marked anemic effects on the mucous membrane, and consequently of great value in conjunctivitis simplex, phlyctenularis, pterygium, keratitis vascularis superficialis, iritis, scleritis, etc. This preparation is a constrictor and not an astringent, the cells being unaffected by it, consequently it may be used in combination with zinc as an astringent. It may also be combined with calomel and yellow ointment. In probing the tear duct very good results are obtained by combining adrenalin with the cocain. As a cosmetic it is said to enlarge the palpebral fissure more than cocain. Dionin is another preparation used by the author in the treatment of keratitis parenchymatosa in recent cases only. It is of no value in long-standing cases, and is contra-indicated in diseases of the conjunctiva. It shortens the course and stops the pain in iritis. Many authors recommend it in choroiditis, retinal hemorrhages, and vitreous opacities. In cataract operations it facilitates the absorption of the lens residue. The effect of dionin is due to the fact that it produces changes in the epithelium of the capillary vessels and causes an increase in the secretion of the blood-plasma into the connective tissue which increases the nutrition of the cells. The circulation of the lymph in the anterior part of the eye is accelerated, which benefits the posterior part of the eye bulb. Stasis in the lymph channels produces pressure on the nerve ends and in this way the analgesic effects of the drug are produced, which last for a considerable length of time.

Protargol and largin are the newer remedies substituted for silver nitrate. They are preferable to silver nitrate for the following reasons, as observed by some authors:

1. They are excellent disinfectants.
2. They do not possess such irritant and caustic qualities.
3. They do not decompose so easily.
4. They are less harmful.
5. They do not produce argyrosis.

The author's views do not entirely coincide with those given above, claiming, as he does, that they do produce argyrosis and decompose easily. He does not believe that they can replace silver nitrate, but thinks they are very valuable adjuvants to it.

Coblentz states that silver nitrate possesses only limited penetrating power, as it is precipitated by albumin and sodium chlorid and thus does not reach the deeper tissues. The more recent preparations are unaffected by the albumin or sodium chlorid, and hence their penetrating and germicidal power is increased.

He mentions several of the recent preparations, together with their composition. Largin, according to this author, is a paranucleo-proteid with silver, containing 11.1 per cent. of silver. It is soluble in nine parts of water, is non-irritating and has high penetrating power. Protargol contains about 8 per cent. of silver and is soluble in equal parts of water. It penetrates deeply and is not precipitated by the tissues. Argyrol, which is placed in the front rank by some authors in the treatment of eye affections, contains 30 per cent. of the metal. It is readily soluble in hot water.

In the author's opinion these preparations are all less irritating than nitrate of silver and are better borne by the patient. The percentage of silver is of less importance than the special combination in which the silver exists.

Tissol, in *Med. Press and Cir.*, states that of all the mydriatics atropin is the best. Its indications are: phlyctenular keratitis or impetigo of the cornea, herpes of the cornea, and interstitial keratitis. The atropin relieves the pain and by dilating the pupil prevents the formation of synechia. Mydriatics are especially of benefit in affections of the iris. Sometimes the eye is too sensitive to the ordinary solution, which is:

℞. Atropinæ ..... gr. i
Aq. destil. ..... ʒiiss 10 | 06

In such cases the following solution in warm compresses on the eye serves the purpose:

℞. Atropinæ ..... gr. vi
Aquæ ..... ʒi 30 | 40

M. Sig.: One teaspoonful in a bowl of water and applied to the eye on compresses.

Or the following combination may be used in its stead:

℞. Ext. belladonnæ
Ext. hyoscyami, āā ..... ʒss 2
Aquæ ..... ʒx 300

M. Sig.: Apply locally on compresses.

As mydriatics raise ocular tension they are absolutely contra-indicated in glaucoma. Myotics are proper in such conditions, producing myosis, lowering tension and decreasing the

conjunctival secretion. Pilocarpin and eserin are included in this class. Pilocarpin is a less painful and more untrustworthy remedy.

The following formula is recommended by Darier:

℞. Pilocarpinæ hydrochlor.	gr. i	06
Eserinæ sulph.	gr. ss	03
Ext. suprarenalis aqueous		
Aquæ destil, āā	℥iss	45

M. Sig.: As a myotic in glaucoma.

Methylene Blue in Diarrhea.

Combemale, according to an abstract in *Med. Press and Cir.*, strongly recommends the administration of three grains daily of methylene blue in the treatment of diarrhea from any cause. He has employed this agent with success in the diarrhea of tuberculosis, Addison's disease, and typhoid fever, and in the diarrheas of other acute infections. He gave it in doses of one grain three times a day, or it may be given oftener in smaller doses.

Diarrhea in Typhoid Fever.

L. F. McDowell, in *Dublin Jour. of Med. Science*, recommends the following combinations in the treatment of diarrhea in typhoid fever:

℞. Tinct. opii camph.	℥ss	2
Acidi sulph. arom.	gtt. xv	1
Spts. chloroformi	gtt. x	65
Aquae	℥ss	15

M. Sig.: To be taken at one dose and repeated as indicated; or:

℞. Bismuthi carb.	gr. x	65
Sodii bicarb.	gr. v	30
Cretæ prep. arom.	gr. xx	1 30
Tinct. opii	gtt. v	30
Spts. chloroformi	gtt. x	65
Sodii salicylatis		
Pulv. tragacanthæ, āā	gr. x	65
Aquæ q s. ad	℥i	30

M. Sig.: At one dose.

Epilepsy.

W. Alessi, according to an abstract in *Amer. Med.*, recommends the following combination as of great value in the treatment of epilepsy:

℞. Sodii arsenatis	gr. 1/64	001
Zinci phosphidi	gr. 1/14	005
Calcii phos.	gr. i	06
Sodii benzoatis		
Pancreatin, āā	gr. iii	20

M. Sig.: At one dose three times a day before each meal.

According to the author, the arsenic and zinc preparations are nerve tonics, the latter being also a nerve sedative, the former aiding the exhalation of nitrogen. The calcium phosphate reduces cerebral excitability. The pancreatin and sodium benzoate aid digestion and overcome intestinal fermentation.

Chronic Pharyngitis.

The following combinations are recommended by *Jour. des Pract.* in the treatment of pharyngitis:

℞. Sodii boratis	℥ii	8
Tinct. myrrhæ	℥i	4
Infusi cocæ fol.	℥viii	240

M. Sig.: Use as a gargle every two hours; or:

℞. Potass. chloratis	℥iiss	10
Infusi rubi fol.	℥iv	120
Infusi cochleariæ	℥ss	15

M. Sig.: To be used as a gargle.

To Kill Bedbugs.

In response to an inquiry by a subscriber in our last issue as to the best method of killing bedbugs, Dr. W. A. Kriesel of Milbank, S. D., recommends the use of formalin as being more efficient than the bichlorid solution. The room should be at a temperature of 70 F. or warmer in order to promote more rapid evaporation of the solution, thereby affecting the bugs that may have escaped the fluid. The fluid should be introduced into all the cracks and crevices by means of an ordinary oil can. The application should be repeated after five or six days in order to kill any young bugs hatched from eggs not devitalized by the first treatment. The hands must be protected by gloves in order to avoid any escharotic effects. Dr. Kriesel has used this for three years and has never seen it fail.

Dr. J. W. Croskey, Philadelphia, recommends, as a practical and sure remedy for bedbugs, a solution composed of equal parts of spirits of turpentine and aqua ammoniæ applied in the same manner as the foregoing formalin solution.

Burns.

The following is recommended by *Nord Medical* in the treatment of burns:

℞. Tinct. opii	℥iss	6
Aq. laurocerasi	℥x	40
Glycerini	℥iiss	75

M. Sig.: Apply constantly to the inflamed areas by means of compresses.

Lumbago.

The following combination, in *Med. Rev. of Reviews*, is recommended in the treatment of lumbago:

℞. Tinct. iodi	℥ii	8
Tinct. aconiti rad.	℥iii	12
Spts. chloroformi	℥ss	15
Linimenti saponis co. q. s. ad	℥iii	90

M. Ft. linimentum. Sig.: Apply locally several times daily.

Diphtheria.

E. Perrier, in *Annals de Med. et Chir.*, states, in the treatment of diphtheria, that the presence of suspicious spots on the tonsils or uvula demands the injecting of antitoxin at once. Irrigation of the upper-air passages should be practiced three or four times a day with a warm boric acid solution. Locally the following combination should be applied every two hours during the day and less frequently at night:

℞. Acidi salicylici	gr. x-xv	.65-1
Alcoholis	℥v	20
Glycerini	℥i	30
Infusi eucalyptus	℥ii	60

M. Sig.: Apply locally to the throat every two hours.

The patient should be nourished with milk, albumin water, chocolates and ices, as well as raw or cooked fruits. If alcoholic stimulation is required, champagne, sherry or port wine may be selected.

The following tonic is recommended:

℞. Ext. cinchonæ	℥i	4
Cognac	℥i	30
Elix. simplicis	℥iv	120

M. Sig.: A teaspoonful to a dessertspoonful every two hours.

In case the nasal fossa is involved the following ointment may be applied:

℞. Acidi boracici	℥i	4
Liq. petrolati	℥i	30

M. Sig.: Apply locally.

In cases in which the diphtheritic membrane appears on the conjunctivæ the general treatment is the same, while the conjunctivæ are treated locally by the application of boric acid.

Medicolegal.

SOME LEGISLATION OF THE YEAR 1903.

Nevada—Requirements for Practice of Optometry.—Chapter 48 of the Laws of Nevada of 1903 provides that any person engaging in the optical profession in correcting ocular, muscular imbalances, errors of refraction, or other defects of vision, not requiring surgical treatment, shall apply to the state controller for a license and shall produce a certificate of graduation, and shall make affidavit that he is the person named therein, and that such certificate has been issued by a regularly chartered college, authorized to confer degrees, etc. The fee for a license is $10. Nothing in this act shall be construed as applying to regularly qualified medical practitioners, nor to persons who have been engaged in the optical profession in the state for one year preceding the passage of this act.

North Carolina—To Keep Mumps and Itch Out of Schools.—Chapter 690 of the Public Laws of North Carolina of 1903 amends Section 13 of Chapter 214 of the acts of 1893, providing that school committees, etc., shall not allow pupils to attend schools while members of their respective households are sick with certain diseases, or during two weeks after the death, recovery or removal of such sick person, Chapter 690 adding to the list of diseases mumps and itch.

North Dakota—Regulation of Practice of Optometry.—Chapter 130 of the Laws of North Dakota of 1903 is for the most part like the California act epitomized on page 1043 of THE JOURNAL, Oct. 24, 1903. But it contains as further causes for the revocation of a certificate the advertising himself as an eye specialist or doctor, or holding himself out to the public as being other than an optician, skilled in the art of optometry.

Oklahoma—Provision for Free Distribution of Vaccine.—Article 3 of Chapter 2 of the Session Laws of Oklahoma of 1903 appropriates $2,500 per annum, or as much thereof as may be necessary, for the manufacture of and free distribution within the territory of vaccine by the Oklahoma Agricultural Experiment Station at Stillwater.

Oregon—Reports Required.—On pages 82-86 of the General Laws of Oregon of 1903 is an act to establish a state board of health, etc., which provides, among other things, that it shall be the duty of every physician, midwife or head of a family, under whose charge any birth occurs, to report the same to the county or city health officer (as the case may be) before the last day of the month in which said birth occurs. Similar provisions require deaths to be reported within forty-eight hours, or as soon thereafter as practicable; and any infectious or epidemic disease to be reported immediately. The penalty for violation is a fine of from $10 to $100.

Pennsylvania—For Sanatorium for Poor Consumptives.—No. 430 of the Laws of Pennsylvania of 1903 appropriates $8,000 for the erection, fitting and maintenance for two years of a sanatorium for poor consumptives, on the state forestry reservation at Mont Alto, in Franklin or Adams counties, and authorizes the commissioner of forestry to make and enforce rules and regulations governing the same.

Pennsylvania—Limits Sale and Prescribing of Cocain.—No. 192 of the Laws of Pennsylvania of 1903 provides that no person shall sell, furnish or give away any cocain, or any patent or proprietary remedy containing cocain, except on the prescription of a registered practicing physician, or of a dentist, or of a veterinarian; nor shall any such prescription be refilled; nor shall any physician, etc., prescribe cocain, etc., for any person known to him to be a habitual user of cocain. The penalty is a fine of $100 or less, and imprisonment for six months, or less, both or either, at the discretion of the court.

Pennsylvania—School Buildings To Be Disinfected.—No. 132 of the Laws of Pennsylvania of 1903 states that, whereas, infectious and contagious diseases are very largely disseminated through the schools, from the want of proper disinfection of school buildings; therefore, it shall be the duty of the board of school directors, trustees, or other persons having control of any school or college building, to adopt and immediately put into operation a modern system, for the disinfection of such buildings; and to cause, at regular intervals of not exceeding two weeks, all of such buildings to be thoroughly disinfected. The system adopted shall be approved by the city board of health, or, there being no such local board, by the state board of health.

Pennsylvania—Provision for Commitment of Drug Users.—No. 153 of the Laws of Pennsylvania of 1903 is an act to authorize and provide for the commitment of persons habitually addicted to the use of an intoxicating liquor or drug to a proper hospital or asylum, for restraint, care and treatment. The petition shall be accompanied by the affidavits of at least two physicians, based on examination by them of the alleged drunkard, setting forth his condition and stating that restraint, treatment, etc. in a hospital will be of benefit, which physicians must also appear at the hearing given the case. But the restraint shall not be continued in any case longer than one year, and all commitments shall be reviewable by proceedings under writ of habeas corpus, which may be sued out at any time. Furthermore, no person shall be commited, or be admitted into any hospital, etc., until payment has been made, or satisfactory security given, for the proper charges for board, treatment, etc.

South Carolina—Ban on Toy Pistols and Caps.—Chapter 79 of the Laws of South Carolina of 1903 provides that it shall be unlawful for any person, firm or corporation in the state to sell, keep for sale or offer for sale, or give away, any toy pistol, in which caps or cartridges are used, or any caps or cartridges therefor. The penalty for violation is a fine not exceeding $100, or imprisonment (in the case of an individual) for not over 30 days.

South Dakota—To Prevent Abuses in Vaccination.—Chapter 223 of the Laws of South Dakota of 1903 makes it unlawful for any board, physician or person to compel another by physical force to submit to vaccination with smallpox or other virus. No person shall prevent a child of school age, who furnishes a physician's certificate of sucessful vaccination within five years, from attending public school. The penalty for violation is imprisonment for not more than thirty days or a fine of not more than $100 or both.

Texas—Restriction on Prescribing Cocain, Etc.—Chapter 115 of the General Laws of Texas of 1903, regulating the sale of morphin, opium, cocain, chloral or any of the derivatives thereof, provides that any physician or person who shall give any prescription therefor to any person known to be a habitual user of the same, except in cases of actual sickness, shall be fined from $25 to $250, and may in addition be imprisoned in the county jail not exceeding six months.

Texas—Creates a Pasteur Hospital.—Chapter 125 of the General Laws of Texas of 1903 appropriates $5,000, or so much thereof as may be necessary, for the erection and maintenance of a Pasteur department for the treatment of hydrophobia in the state, in connection with and under the management of the state lunatic asylum at Austin. Any person affected with hydrophobia within the state shall be admitted for treatment on the certificate of a practicing physician and the recommendation of the county judge of any county. All indigent patients shall be treated and maintained at expense of the state, but all non-indigent patients at their own expense, or that of their relatives, friends or guardians. The laws pertaining to the introduction and control of such patients shall be the same as those of the Austin asylum.

Utah—Children Forbidden to Have Tobacco, Etc.—Chapter 135 of the Laws of Utah of 1903 provides that any person under the age of 18 years who shall buy, accept or have in his possession any cigar, cigarette or tobacco in any form, or any opium or any other narcotic in any form, shall be guilty of a misdemeanor

Utah—Restriction on Location of Pest-Houses.—Chapter 36 of the Laws of Utah of 1903 provides that no pest-house, hospital, etc., used to confine persons having or suspected of having any contagious or infectious disease, shall be located or maintained within twenty rods of any public road, or within one-fourth mile of any uncovered canal, ditch, flume, etc., conveying running water only, if said water is conveyed into, or used by the inhabitants of any city, town or village, for culinary, household or other domestic purposes.

Utah—Disinfection Required in Typhoid Fever Cases.—Chapter 81 of the Laws of Utah of 1903 makes it the duty of any person having charge of a person with typhoid fever to disinfect all excreta from the person during the disease, in accordance with the rules of the state board of health; failure so to do shall be a misdemeanor. It shall be the duty of the physician in attendance to personally instruct those having charge to perform the disinfection described and to satisfy himself that the same is properly carried out; failure so to do shall be a misdemeanor.

Wyoming—On Sale and Prescribing of Delirifacients.—Chapter 98 of the Session Laws of Wyoming of 1903 makes it unlawful for any person, corporation, etc., to sell, give away, or

possess, or in any manner distribute, any cocain, opium chloral hydrate, or their derivatives, or any drug or combination, the natural effect of which is to induce delirium, or any patent or proprietary medicines, known to contain any drug, or derivatives thereof, heretofore mentioned; except that regular licensed pharmacists may keep for sale and sell such drugs, on the bona fide written prescription of a regular practicing physician, which prescription must not be repeated or refilled. Any physician who shall prescribe any of the drugs herein mentioned, except in cases where the use is required by the then existing physical or mental condition of the patient, shall, on conviction thereof, be deemed guilty of malpractice and unprofessional conduct, and it shall thereon be the duty of the State Board of Medical Examiners to revoke his license to practice.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

New York Medical Journal.

November 28.

1. *The Use of Weak Cocain Solutions in Operations for the Removal of Cervical Tumors. Frederick Griffith.
2. *The Early Operative Treatment of Tuberculous Osteitis of of the Knee. (Concluded.) Bernard Bartow.
3. *The Treatment and Management of Postoperative Tuberculous Patients and a Plea for the Establishment of Seaside Sanatoria and Convalescent Homes. S. A. Knopf.
4. *The Treatment of Acute and Subacute Anterior Gonorrhea by Retrograde Injections of Stronger Solutions of Silver. (Continued.) Hermann G. Klotz.
5. *Ocular Headache and Other Ocular Reflexes; a Statistical Study. (Concluded.) M. W. Zimmermann.

1. **Cocain Anesthesia.**—Griffith reports a number of cases of cervical tumors removed under weak solutions of cocain, ¼ to ⅛ per cent. in a warm, weak, soda solution. In one of the cases ether supplemented the cocain on account of the nervousness of the patient. In the others there seemed to be little or no pain during the dissection.

2. **Tuberculous Osteitis of the Knee.**—Bartow's article is concluded in this issue, and the paper consists mainly of accounts of cases. The range of preservation of movement in the recovered cases was from complete functional restoration to limitation of the movement within 15 degrees of flexion. Between these extremes are 4 cases in which there was free flexion of from 60 to 90 degrees from the straight position of the leg. In a patient with less motion range it is susceptible of further improvement by movement during anesthesia.

3. **Post-Operative Tuberculous Patients.**—Knopf's article is a very long one, covering the whole subject of the hygiene of tuberculous patients after operation. He describes the methods for the open-air treatment and exercises, and insists on deep breathing movements as soon as possible after the patient is removed from the table, to restore the respiratory function and facilitate hemostasis and expectoration and relieve the cough. It also prevents hypostasis of the lungs often produced by the prolonged recumbent position. There should be individualized hydrotherapy. Rest in the open air is considered of special importance. The dietetic treatment must vary with the cases. He believes in a mixed, nourishing diet with thorough mastication and avoidance of all alcoholics and too much sweets; plenty of salt with the food, and between meals plenty of water. The administration of raw beef or beef juice will be of benefit in all types of tuberculosis. A great factor in the success is the keeping up of perfect nutrition; massage is valuable in suitable cases. It would be impossible, however, he says, to lay down a rule when it is or is not indicated after surgical operations. He goes at length into the precautions that should be taken to avoid infection, the care of the sputa, etc. In conclusion he makes a plea for convalescent homes for the poor who have undergone surgery.

4. **Gonorrhea.**—Klotz' article is continued. He describes the method of treatment in the various forms and stages.

5. **Ocular Headache.**—Zimmermann's article is here concluded. He gives a tabulated statement of the results of re-examinations after six months or more, the average being 2.88 years. These offer some interesting data. He also tabulates cases where there was a lack of binocular vision in the first place, either due to a loss of an eye or divergent strabismus, and in which ordinary muscle action would seem to be eliminated. This group shows a much smaller percentage of headaches than that of the larger groups with binocular vision. The influence of ill health as a predisposing cause of ocular headache is also studied, and it is found to occur in 19.16 per cent. Neurasthenia, general nervousness or general ill health seemed to be prominent causes, though grippe also played a considerable figure. Migraine, understanding by this term a form of periodic headache preceded by aura, occurred in 33 cases, excluding 35 cases of hemicrania without nausea and vomiting, 25 of bilateral headache in which these symptoms appeared. Eight patients reported complete cures of migraine attacks for a reasonable period, and in 3 cases a certain degree of relief was obtained by the proper adjustment of glasses. He remarks that oculists have perhaps been too indifferent to the headache habit with which neurologists are well acquainted. During the early wearing of new glasses, while the eye and its ciliary muscle are adapting themselves to new conditions, great benefit results from the use of very dilute applications of a meiotic, eserine salicylate, 1/20 to 1/50 of a grain to the ounce. He thinks this, perhaps, acts as a tonic to the ciliary muscle and has a tendency to steady its erratic action under new conditions. With these weak solutions there is very little effect on the pupil. They are not irritating to the iris or other uveal structures, and are for temporary use only. With periodic headaches, some of the coal tar group, the preparation given at the onset of the attack may be of great benefit. The tabulated statement of other reflexes than headache, including epileptiform attacks, vertigo, shoulder pain, abnormal head position and blepharospasm, is also given. In one of the cases of epileptiform attacks ocular treatment seemed to produce a cure. The total results of treatment are rather hopeful. In 233 hospital cases and 451 private ones a complete cure is reported, also 29 and 61 per cent., respectively, of improvement. Only 20 cases were not improved. He thinks that the 86 per cent. of cures is a good result, not meaning by this absolute cures, though that is commonly the outcome, but such a modification of symptoms that the patient does not suffer any annoyance which can not be controlled by hygiene.

American Medicine, Philadelphia.

6. *What Is the Limit of Safety When More Than One Operation is Indicated? Albert Vander Veer.
7. *The Roentgen Rays as a Palliative in the Treatment of Cancer. Charles Lester Leonard.
8. *The Demonstration of Nucleated Red Blood Corpuscles in Animal Spleens. Edward T. Williams.
9. *The Spectroscopic Elements of Light as Therapeutic Agents. George G. Hopkins.
10. *Abdominal and Pelvic Surgery Without Ligatures. Electrothermic (Heat and Pressure) Hemostasis. Andrew J. Downes.
11. The Effects of the Secondary Static Currents in Removing Albumin and Casts from the Urine, with Report of Cases. Boardman Reed.
12. Status of Sanitary Progress. Walter Wyman.

6. **Multiple Operations.**—The dangers of multiple simultaneous operations are pointed out by Vander Veer who, while he admits the possibility of recovery in such cases, thinks the dangers are increased. The danger to certain nervous tissues in doing what we call a combined operation must not be lost sight of, and any operations that approach the stomach, that involve the small nerve centers, are especially to be respected. Operations on the genitals of males are not well borne, and he thinks the same should be true in the female, though gynecologists are quite free in making multiple operations in these cases. In the operation of nephrectomy he does not like to do more than one operation on one patient at one time, and the same holds good in operating on the lung or opening the pleural cavity. One operation on the brain is quite enough. He concludes by

saying that he believes extreme multiple operations, deliberately planned, should not be encouraged, although the surgical technic of to-day allows us to do more than was even dreamed of in the near past.

7. **Cancer.**—Leonard believes that the *x*-ray should be used in cancer, though we can not give up surgical measures with our present knowledge. The rays should be used in combination. The palliative effects of the rays also are important. He insists on the necessity of correct technic, a careful study of the patient's condition, use of stimulants, a tonic course of treatment if necessary to combat the tendency to degeneration of the cells and possibly auto-intoxication. He says he has seen inoperable cases of cancer cured and remain cured thus far, and hopelessly inoperable cases restored to such health as to be able to resume their ordinary vocations, while the fatal termination in hopeless cases has been deferred and the suffering mitigated. The results thus far are very encouraging. A prophylactic postoperative course of treatment has been developed that will doubtless increase the number of cures, while as a palliative agent there is nothing else equal to it.

8. **Red Blood Corpuscles in the Spleen.**—Williams has experimented on the spleens of hogs and oxen and finds that the erythroblasts are a constant anatomic element in these structures. He has not yet been able to examine a fresh human spleen, opportunity for which is not too common, but thinks we need further evidence before we can say that this organ in man has lapsed into a rudimentary state and is incapable of making red blood corpuscles. When an authority like Neumann positively states that he has seen erythroblasts many times in the spleen of human adults and distinctly expresses his dissent from Kölliker, we are evidently nearing the verdict.

9. **The Spectroscopic Elements of Light.**—Hopkins notices the history of the light treatment and describes the effects that he has himself obtained with the Finsen light, the Minim light, the Hopkins lamp and the German light bath.

10. **Electrothermic Hemostasis.**—Downes' article is a description of his methods and armamentarium, and a new record of cases up to the present time.

Medical Record, New York.

13 *Electricity in General Practice. W. B. Neftel.
14 *Suprapubic Lithotomy. J. J. Brownson.
15 *Treatment of Cervical Adenitis Due to Tonsillar Infection. Albert E. Rogers.
16 Perineal Section for Stricture, with Suggestions on the Use of the Cautery, and Points in the After-treatment. Charles C. Miller.
17 Foreign Bodies in the Rectum, with Report of Two Cases. Maurice Rosenberg.

13. **Electricity in General Practice.**—Neftel reviews the utilization of electricity according to the older methods of galvanism and faradism as they can be employed by the physician in general practice. He notices the use of faradic currents as being a local and general stimulant and tonic, and affecting general nutrition, while galvanism acts more directly on the nerves and nervous centers, modifying their excitability. The contraindications to both are fevers and acute inflammatory disease. The different methods of application are described, faradization of phrenic nerves in cases of suspended animation and of the nerve trunks in the treatment of writers' and piano players' cramp, in visceral displacement and dilatation, in hernia, general anemies, etc. He also gives instances of the use of galvano-faradic currents in atrophic conditions and of faradic currents in heart disease. Galvanization of the brain and the sympathetic nervous system and pneumogastric are illustrated by examples and the use of the galvanic current in neuralgia. In neuritis the faradic current is indicated. The methods are described much as in the usual text-books on electro-therapeutics.

14. **Suprapubic Lithotomy.**—Brownson advocates the use of the suprapubic method in lithotomy, claiming that the danger of hemorrhage is not so great; there is no fear of wounding the rectum; the peculiar and delicate nerve supply of the perineum is not disturbed, moreover, and the operator has better control of the bladder by the suprapubic method. After operation he would use drainage except, perhaps, in young and vigorous persons with healthy bladders, where the catheter can be employed.

15. **Cervical Adenitis.**—In case of cervical adenitis from tonsillar infection Rogers advocates removal of the tonsils, and advises that in all cases in which the glands have not already broken down, the surgeon should first extirpate the tonsil before resorting to incision through the skin, thus removing a primary source of infection and avoiding an unsightly scar. Five cases are reported.

Boston Medical and Surgical Journal.

November 26.

18 *The Treatment of Diffuse Peritonitis. B. F. Lund.
19 *A Clinical Study of 112 Cases of Movable Kidney. Ralph C. Larrabee.
20 *Diseases of House Officers in Hospitals. William R. P. Emerson.
21 *Unclean Milk, Bovine Tuberculosis and the Tuberculin Test—Their Relation to the Public Health. (Concluded.) E. R. Larned.

18. **Peritonitis.**—The starvation method of treating peritonitis described by Ochsner and others is not favored by Lund, who insists on the importance of early operation, with thorough irrigation with decinormal salt solution at a temperature of 110. He is also an advocate of gauze drainage, as these wicks, used even only a few hours, by capillarity will remove a large quantity of fluid, some of it presumably septic. The irritating effect of the gauze causes immediately after the drainage of the fluid the formation of adhesions which wall off the infected area and prevent further reinfection. For drainage of the pelvis he uses gauze wicks, and among them places a glass tube, not on account of its value as a drain, but to keep the gauze in the original position and prevent its being entangled by intestinal movement. He also advocates the elevation of the head of the bed, and his own experience with this has been satisfactory. Reference is also made to an article on enterostomy in selected cases of peritonitis, published in THE JOURNAL for July, 1903. The procedure has proven effective in desperate cases. For details the reader is referred to the original. In looking over his records he finds he has operated in 34 cases of general peritonitis, not including cases covering only a slight area; 23 of these were due to perforative appendicitis, of which 10 recovered and 13 died, most of the fatal cases being in a very poor condition. Of the 11 remaining cases 4 were due to salpingitis; 1 recovered and 3 died; 1 due to perforative typhoid ulceration also died; 2 to rupture of the intestine by external violence, with 1 recovery and 1 death; 1 to perforated gastric ulcer, which recovered; 1 fatal case due to perforating duodenal ulcer; 1 to perforation of the posterior cul-de-sac by a splinter of wood introduced through the vagina. This forms a total of general peritonitis from all cases of 34 cases, with 20 deaths. The mortality of the early cases has been low, and it should be remembered, as stated above, that a number of cases of slight peritonitis were not included in these figures. In view of the recent advocacy of the rest treatment of peritonitis and of the great conflict of opinion as regards the methods, he thought it best to present his reasons for his own attitude on the subject.

19. **Movable Kidney.**—One hundred and twelve cases of movable kidney were detected in 272 out-patients at the Boston City Hospital during Larrabee's four months' service in 1902, children not included. The right kidney alone was affected in 98 of the 112 cases. Movable kidney seems to be most frequent in young adult life, but there were 5 cases over 60 years of age and 1 over 70. Of the 93 Americans in the series, 37 per cent. had this condition; of the 69 Irish, 51 per cent.; of 41 natives of British provinces, 49 per cent., and of 22 Russian Jews, 30 per cent. It was found a little more frequently in the married and widowed than in single women, though the difference was not very great. Fifty of the cases were multiparæ; 1 a unipara; 51 had never been pregnant. The cases showed markedly the effects of emaciation as a causal factor. Trauma was given as a probable cause in one instance, and all but 9 patients were either cor-

sets or other constricting articles of clothing. The symptoms were not characteristic, but were as noticeable in cases without floating kidney as in those with it. In no case was there any evidence of hydronephrosis, gangrene, malignant disease, severe hemorrhage or other serious complication. Treatment was thought unnecessary in 87 of the 112 cases, and the patients were not informed of the presence of the anomaly. In 1 case in which this was inadvertently done, symptoms immediately appeared. Two women were advised to wear different corsets; 25 were advised to wear swathes, this being rather for the enteroptosis or laxity of the abdomen in some of the cases. Surgical treatment was not advised in a single instance. Lund says that with over two-fifths of the women of certain classes having movable kidney one ought to be very cautious in attributing such common indefinite symptoms as backache, dyspepsia and neurasthenia to this cause, and when a movable kidney is found it should be borne in mind in treating the case, but unless there is reasonable ground for attributing the symptoms to this it is best not to draw the patient's attention to its existence. The frequency and innocuousness of the lesion would seem to refute the extreme surgical view. Nephrorrhaphy undoubtedly has its place, especially in serious complications such as hydronephrosis or pyonephrosis or severe crises. It is justifiable where there are disabling symptoms that can not be relieved otherwise or when the patient prefers the risk of operation to the discomfort of bandages. It should be remembered that temporary bandaging may tide over a condition of debility during which these symptoms have appeared. Particularly in cases where the symptoms are predominently nervous, one should not advise operation unless the condition and symptoms can be attributed with a reasonable certainty to the lesion.

20. **Diseases of the House Officers in Hospitals.**—Emerson has studied the mortality statistics of house physicians and surgeons in the Boston City Hospital for the past ten years. While the number of cases has been too few and the time too short to offer definite conclusions, the records of the medical and surgical services, 60 men each, and contagious, 70 men, would indicate that the danger of house officers having pneumonia, phthisis or typhoid is very small, only one of these cases occurring in the medical service, and then in an individual of low resistance. The nasopharyngeal and febricular affections occurred in the ratio of 12 in the medical staff to 1 either surgical or pathologic. The danger of infection in the examination of moist cultures and sputum is very slight, and there is little evidence in the ten years' records that a house officer's general condition is a marked factor in the question of infection by a contagious disease. In six months' service the chance of a member of the service taking diphtheria infection, including mild cases, is one in two, of scarlet fever, one in seven. The influence of improved living quarters and facilities for proper exercise on the health of house officers is marked. It should be urged on house officers that the sense of fatigue occurs more often as a result of nervous tension and indoor air than of muscle exhaustion, and that it is relieved by proper exercise and baths. The tabulated comparison of the conditions at the end of service of men who exercised and men who did not is so striking as to demand that the attention of all similarly situated persons be given to this matter.

21. **Bovine Tuberculosis.**—Larned concludes his article in this issue, and insists on the importance of the tuberculin test by which it is possible to very materially reduce tuberculosis in cattle and, it may be, to eventually exterminate it.

22.—See also abstract 36 below.

23. **Mastoid Disease and Cerebellar Abscess.**—Oppenheimer describes the conditions and mechanism of cerebellar abscess from mastoid disease and the general treatment of the condition, pointing out that it may be, in the second stage, practically latent for a considerable time. The third stage supervenes with the symptom group characteristic of severe otitic intracranial infection, the symptoms sometimes pointing to the localized cerebellar abscess, but more frequently the condition is only localized after operation. When the first stage is not recognized and the intracranial condition continues without surgical relief, the fourth or the terminal stage is one of gradual death from exhaustion and coma, or sudden, according to the direction in which the abscess ruptures. The first stage is characterized by the symptoms of acute infection and extension of mastoid suppuration to the intracranial contents. The detailed symptoms are given at length. The diagnosis of cerebellar abscess is not always possible by local symptoms: Occipital headache, temperature slightly elevated, normal or subnormal, sometimes nystagmus and paralysis of the sixth nerve, cerebellar ataxia and vertigo if the vermis is affected, a rapid loss of flesh and strength, etc. The multiplicity and confusion of symptoms is very marked. The treatment is necessarily surgical. After the abscess has formed the best plan is to first open and explore the mastoid cells and, failing to find the cause, open the cranium in the groove for the lateral sinus and so obtain access to both the middle and posterior fossæ. A bibliography of 65 references is appended.

24. **Liver Diseases.**—Stoner describes the various conditions of liver disease. Hyperemia he thinks is seldom caused by the two factors to which it is sometimes credited; suppression of menses and hemorrhoidal bleeding. Cirrhosis he accepts as usually the result of infection, either direct or indirect. Alcohol is frequently responsible for the condition even in children. In many cases abnormal fermentation in the bowels is responsible.

25. **Appendicectomy.**—The criticisms of the method of ligation and cauterization of the stump are answered by Lilienthal, who holds that ligation cuts through the mucosa, and in this ways permits occlusion by union of the submucous coats. In cases where there is great infiltration of the walls, with friability, it is best to bluntly crush the rigid root of the organ with a clamp or forceps and then apply the ligature to the crushed tissues. Of course this can not be done with complete gangrene of the stump. The second criticism, that adhesions are apt to form with a stump of this kind, is, he thinks, based on insufficient evidence. He has had the chance of examining post-operative conditions in a number of cases treated by ligation and cautery, and 3 cases of fatal peritonitis examined from three to six days after operation showed adhesions everywhere else but not at the stump, which could not be found. It had been cast off with its ligature, and only a smooth cicatrix on the surface of the cecum remained. In a number of other patients on whom subsequent operations for other conditions were undertaken months and even years after the removal of the appendix, the only evidence of the ligature was a smooth, white cicatrix; no adhesions whatever. He believes, therefore, that the treatment of the stump by the method of ligation is the only way in which adhesions may be avoided. The cauterization he uses is that by strong carbolic acid. A minute drop of the 95 per cent. solution is taken up with a closed artery clamp as ink is taken up with a pen, and after protecting the surrounding tissue with gauze the acid is thoroughly applied two or three times to the mucous lining of the stump until the little funnel is completely whitened. In from fifteen to thirty seconds the stump may be dropped back into the abdominal cavity with no danger to the other structures that may come in contact with it. This method of treating the stump has stood a satisfactory

test in his experience in many hundred operations during the past ten years.

26. **Chronic Villous Arthritis.**—Painter and Erving's article is concluded in this issue. They find that chronic villous arthritis is not a disease of itself, as has been claimed, but occurs associated with chronic diathetic disease involving other tissues, and is representative in such cases of the same pathologic changes that subsequently occur in other structures of the joint. The two principal diatheses which cause this are rheumatoid arthritis and osteo-arthritis. The villous changes are the symptoms, not the disease itself. Traumatism entirely apart from any diathesis, is capable of giving rise to a local villous hypertrophy which goes on to a dense fibrous growth and keeps the joint in a constant state of injury from its traumatic effects. Traumatism associated with an osteo-arthritic diathesis, is frequently the excitant of local synovial hypertrophy, but these changes are more the result of the traumatism than of the stirring-up of the diathesis. Stout flabby adults with pronated or flat feet are more liable to the type of fringe which undergoes fatty degeneration with a minimum amount of fibrous change. This may occur with pregnancy and with the tissue relaxations of nervous prostration and the "soft" condition of so many rapidly-growing and sickly children at the period of puberty. Alteration in the mechanism of weight bearing is not the prime cause of this condition in many of the knee cases, though a frequent contributing factor which should be considered in the treatment, but simple flat feet or pronated feet can hardly cause this condition alone. The operative treatment in selected cases gives eminently satisfactory results when it is fully understood what the operation contemplates. Conservative treatment in suitable cases, though a very small class, gives equally good results. The main thing is to distinguish between the two classes. Judging from the pathologic findings, the condition is the result of a chronic inflammatory process which, acting on the normal villi, cause their hypertrophy with increase of the blood vessels. This becoming chronic on account of the continuation of toxic cause or to intermittent or slight trauma, the vessels are unable to supply the needs of the new tissue, being thus affected by inflammation. They therefore become gradually obliterated by endarteritis with almost complete loss of blood supply and the disappearance of normal fibrous tissue. The latter either undergoes necrosis and hyaline degeneration, or disappears, leaving the tissue that can be nourished by a limited supply of blood, usually the adipose. In this necrotic condition separation of the pedicle and the formation of a loose joint body can easily occur.

29 *Malaria. George J. Monroe.
30 Surgery of the Prostate, Pancreas, Diaphragm, Spleen and Thyroid. (Continued.) B. Merrill Ricketts.

28. **Typhoid Gangrene.**—Ricketts begins his article with a few remarks on the pathology and treatment by amputation. The most favorable cases for this latter are those involving the toes and feet and lower leg during convalescence, and he gives abstracts of reported cases. Spontaneous amputation should not be encouraged, as a rule, though in a few cases in the aged it should be carefully considered. The article is to be concluded in the coming issue.

29. **Malaria.**—Monroe reports a case which apparently in the beginning was that of phthisis and treated accordingly, but it subsequently showed symptoms of malaria controllable by quinin. All the lung symptoms and physical signs disappeared. The patient was an excessive smoker, which is mentioned in connection with the case, though no deductions are drawn.

33 *Colles' Fracture. Fred D. Cartwright.
34 *Fractures of the Femur. H. P. Sights.
35 A Method of Dealing with Fractures. J. B. Taulbee.

33.—This article appeared elsewhere. See THE JOURNAL of August 22, title 144, p. 523.

34. **Fractures of the Femur.**—Sights concludes that while experience and teaching have been discouraging as regards fracture of the neck of the femur, yet with appropriate treatment we may expect bony union. Age is not a contraindication to treatment. The best results are obtained from perfect immobilization and approximation. The plaster-of-paris cast and Buck's extension are not the best methods. The use of suspension apparatus is more comfortable to the patient, convenient to the nurse and favorable as to results. Old ununited fractures can only be relieved by operative treatment, and in these the *x*-ray gives valuable aid.

37 Induction of Labor by Means of a Modified Champetier de Ribes' Balloon. Herbert Old.
38 Anemia Infantum Pseudoleukemica (von Jaksch), George M. Tuttle.

36. **Nephritis.**—Gordon insists on the value of the diet in nephritis, and believes that gout and lithemia are responsible for a large number of cases. He considers that the milk diet should often be discontinued as furnishing too much urea. It also fails to supply the blood with sufficient nourishment or sets up lactic or butyric fermentation. No routine diet should be adopted. In many cases, however, an exclusive milk diet is of value. His own rule is to regulate the diet so as to obtain a normal urine. As long as the urine is normal the kidney will in the majority of cases improve. He remarks as regards nitrogenous foods that fowl, game, fish and eggs are liable to be as bad as butcher's meat in these cases, and especially eggs, which have been disastrous in some cases in his experience. He is not a skeptic as regards drugs, and insists on the use of diuretics and diaphoretics, and extols the good effects of cholagogues, in acute cases especially, and in chronic cases when diaphoresis or diuretics are contraindicated. For emergencies pilocarpin stands by itself. Nitroglycerin is sometimes invaluable in acute cases, and iron is pre-eminent in cases where anemia has set in and the blood vessels need to be nourished. As regards the preparation, he still favors the old tincture of the chlorid. When it fails, other preparations may be used. In anemic convulsions, chloral hydrate and the bromids are useful. He does not hesitate to use morphin where required. Veratrum viride is a drug with which he has had limited experience, but its virtues as a reducer of pulse tension are well established. In acute inflammatory conditions with strong pulse, aconite is valuable. For the debility of subacute and chronic nephritis, stimulation must be employed, and alcohol may be beneficial in elderly people—best given with the food. Strychnin is useful in many cases when the pulse is soft, thin and frequent. Taken all in all, it is the best remedy in our possession for weakness and exhaustion of the nervous system, while with hypophosphites it will stimulate with results unattainable by either drug alone.

45 The Tonsil Snare. W. H. Peters.

40. **Adenoids in Adults.**—The points brought out by Logan are summarized by him in substance as follows: (1) The importance of early recognition of adenoids in children by the general practitioner. (2) Their prompt removal when extensive or interfering with the development of the child, especially in case of exposure to exanthemata. (3) When present in patients suffering from eruptive diseases, attention must be directed to proper disinfection of the pharyngeal vault. (4) In patients exhibiting enlarged faucial glands there generally exist hypertrophies in the vault—the reverse condition does not always obtain. (5) That hypertrophy of the pharyngeal glands in adults is not rare. As a rule, it is dependent on pharyngeal changes during childhood, and is not developed after puberty. (6) That operative interference is warranted in every instance not only to relieve existing dependent conditions, but to prevent impending complications.

41. **Gangrene of the Tonsil.**—Richardson reports a case and remarks on the scantiness of the literature on the subject. The patient died of extreme sepsis. Antitoxin proved ineffective. From a clinical history of the case he thinks diphtheria was not the cause. If it was a case of spirillum infection, it was certainly a very marked manifestation. He is inclined to consider it the result of quinsy, with streptococcic infection causing gangrene and destruction of the tissues.

49 *The Hypodermic Use of Mercury in Syphilis. S. P. Collings.
50 *Pancreatitis Diabetica. Francis T. B. Fest.

46. **Stomach Surgery.**—In most cases of diseases of the stomach requiring surgical interference there is defective drainage, though not infrequently extra-gastric conditions give rise to the symptoms. The diagnosis is described by Ochsner, who calls attention to gallstones as the first possibility of confusion, and points out the differences between their symptoms and those of gastric ulcer, such as pain to the right around the side and back and in the vicinity of the liver, pain and tenderness between the junction of the ninth rib and its cartilage and the umbilicus. He also remarks as regards gastric crises of locomotor ataxia. All of the stomachic conditions can be relieved by making a gastroenterostomy between the lowest point of the stomach and the jejunum, large enough to permanently drain the organ. For this purpose he advocates the McGraw elastic ligature which he has used in his last 34 cases. It is easy of application, the fact that neither the intestines or stomach are opened and that the anastomotic opening can be made long enough to prevent future obstruction due to its contraction are advantages. He says:

1. A round rubber cord 2 mm. in diameter, made of the best material, should be used. 2. A posterior row of Lembert sutures is applied. 3. A long, straight needle armed with the rubber ligature is passed into the lumen of the intestine and out again at the desired distance, from 5 to 10 cm. away from the point of introduction. 4. While an assistant holds the intestine the surgeon stretches the rubber in the needle, and when quite thin draws it rapidly through the intestine. 5. The same step is repeated through the stomach. 6. A strong silk ligature is placed across and underneath the rubber ligature between the latter and the point where the stomach and intestine come together. 7. A single tie is made in the rubber ligature after the latter has been drawn very tightly. 8. The silk ligature is passed around the ends of the rubber ligature where they cross and tied securely three times. 9. The ends of the latter are released and cut off, being held by the silk ligature. 10. The Lembert suture is continued around in front until the point of its beginning is reached, where it will be tied. 11. Care must be exercised to prevent tying the rubber too far backward, and thus getting behind the posterior row of Lembert sutures.

He is thus explicit in describing the steps of the operation since he finds that a thorough familiarity with the method seems to give good results. He has not had satisfactory experience with the pyloroplasty, but the Finney method is undoubtedly the best, and it should be restricted to cases where there is a sufficient amount of tissue to make the new pyloric opening very large. Pylorectomy will, he thinks, be more and more employed and should always consist in the excision of more than 3 cm. of duodenum beyond the malignant growth and the removal of at least two-thirds of the stomach together with the lymphatics and the lesser omentum, even when the carcinoma is not advanced. This is important because the lesser curvature of the stomach is likely to be infected to a considerable distance from the original growth even in the earlier stages. Gastrectomy can be indicated only in a very small number of unusual cases. Gastrostomy is indicated in all cases of obstruction of the esophagus due to carcinoma in which starvation is imminent, and in cases suffering from benign stricture which can not be dilated from above. This operation is here indicated for the purpose of making retrograde dilatation. It is not likely that gastroduplication will ever again be in favor in the future. Elevating the stomach in gastroptosis is an operation still to be tested, though some authors, notably Beyea, speak well of it. Ochsner's own observation has convinced him that in severe pathologic lesions which can not be relieved medicinally in a reasonable period, nor traced satisfactorily to a neurosis not secondary to gastric disease, nor to other conditions mentioned, surgical treatment is indicated and should be undertaken reasonably early.

47. **Obstruction from Gallstones.**—Tupper reports his case and discusses others in the literature. He concludes from the whole that when bowel obstruction occurs in patients who have had inflammatory trouble in the region of the right hypochondrium, erratic gallstones are to be considered as a probable factor, and more probably in a woman past middle life. On account of its proximity and the fixedness, the duodenum is the most frequent avenue of escape for calculi ulcerating from the gall bladder. The colon is next in order. Other portions of the small intestine are rarely perforated. The calculi entering the duodenum are generally carried farther into the small intestine and arrested in their progress by the gradual diminution in the lumen of the bowel. Gallstones ulcerating in the colon rarely cause obstruction, but are usually passed readily per rectum. When gallstones smaller than the lumen of the intestine cause obstruction, it is probably because of the so-called "decubital irritation and angulation" of Pilcher. The site of bowel obstruction can be often approximately located by symptoms such as the presence or absence of meteorism and the presence or absence of bile and feces in the vomit. The lower portion of the small intestine is frequently the site of obstruction caused by migrating gallstones. Lodgment in the lower duodenum is rare. Lodgment in the duodenum between entrance of the bile duct and the pylorus must be exceedingly rare. He found no case on record except the one here reported. The character of the obstructing body in this case was also unique in that it consisted of a collection of faceted calculi rather than the single large gallstone usually found.

49. **The Hypodermic Use of Mercury in Syphilis.**—Collings advocates the hypodermic use of mercury. After considerable experimentation he has adopted the following solution made up in a 2 per cent. solution of chloretone:

℞.	Hydrargyr bichloridi, C. P.....grs. viiss	50
	Sodii chloridi.....grs. iv	25
	Aquæ destil, fl.....3i	4

Mix and make a solution by gentle heat.

	Chloretone .....grs. viiss	50
	Aquæ destil, fl.....3v	20
	Alcoholis absolut.....min. xv	1

Dissolve chloretone in 20 c.c. distilled water, add alcohol and, finally, add the mercury and sodium solution. Shake well and filter.

This makes a 1 to 50 solution of bichlorid, 10 minims representing 1/5 of a grain. It can be given in doses of 5 minims up to 20 or even 25. He gives directions as regards antisepsis and advises the use of the "Sub Q" syringe for injections. The cases to be selected for this treatment are largely those where there is a necessity for the patient to be rapidly brought under the influence of mercury, such as the pernicious or malignant cases, and cases of rapidly destructive lesions, cases of impending paralysis and many cases of cerebral syphilis. It is indicated in fact in all emergency cases unless there are serious contraindications, such as kidney disease. The question of its use as a routine treatment should be decided by each attending physician.

50. **Diabetic Pancreatitis.**—Fest reports a case observed in Honduras and deduces the following practical points from its study:

1. The secretion of the pancreas can become suspended for some time. 2. The secretion of the glycolytic ferment is the first function re-established. 3. The re-establishment of the secretion of the steatolyptic enzyme occurs last. 4. The natural secretion of steapsin and trypsin can be supplanted by the introduction of same per os and of other enzymes as papayotin. 5. Pancreon does away with the necessity of using kreatin-coated pills, pills of pancreatin, which coating is relatively unsafe, as can be demonstrated *in vitro*.

51 Impressions of California Resorts. Guy Hinsdale.
52 *Clinical Observations on Congenital and Acquired Transpositions of the Viscera. James R. Arnelli.

52. **Transposition of the Viscera.**—Arneill has recently had the opportunity of seeing 6 cases of this abnormality, 3 of them within six months, all of which are more or less fully described in this article, as well as 3 others reported to him. He has corresponded with various authorities to find out its frequency and learns that it is comparatively rare in the observation of pathologists. His experience, therefore, is rather singular and he also refers to the literature, especially Gruber's articles which seem to show that partial situs transversus is a much rarer condition than complete transposition.

53 *Questions and Answers Concerning Puerperal Fever.
54 *The Prophylaxis of Puerperal Septicemia. Daniel Longaker.
55 *Treatment of Puerperal Infection. James Hawley Burtenshaw.
56 Puerperal Sepsis. John Chew Applegate.
57 *The Fatty Degenerative Changes in Anemia Are an Attempt on the Part of Nature to Nourish the Patient. Jennie G. Drennan.

53. **Puerperal Fever.**—This number opens with a series of answers by obstetricians to questions on puerperal fever. To the first question, whether there are any possible circumstances in which one would not advise emptying the uterus, the answer is almost uniformly "No." Dr. Leipziger would except the case where the patient is moribund. Dr. Hirst would curette if intra-uterine douching did not control the temperature. The opinions as to the propriety of hysterectomy for suppurative metritis or widespread infection are somewhat various. Dr. Garrigues would advocate it if the general condition is fair, excepting where streptococcal infection is present. Dr. Shoemaker considers it rarely justifiable. Dr. R. C. Norris thinks that the inability to make the diagnosis is considerable and the difficulty is in doing it early enough. When the abdomen has been opened for widespread infection hysterectomy offers the best results. Palmer Dudley, Leipziger and Krusen are unfavorable in their opinions, all holding that if it is to be of service it must be performed early, before general infection, and this involves the unnecessary sacrifice of many uteri. If late, the mortality is great and the operation practically useless. Dr. Hirst would advocate the operation. Disinfection of the hands is insisted on almost universally, and as few examinations as possible. Some, like Leipziger, would use rubber gloves, as would also Krusen and Hirst. Intra-uterine douching is used by Garrigues and by Hirst when he suspects gonorrhea. Krusen considers it useless if the uterus is thoroughly contracted and no major manipulations have been required. The intravenous injection of formalin solution in the treatment of general streptococcic infection has not been observed to have had beneficial results by Shoemaker and Norris, while Leipziger, Krusen and Hirst have never tried it. Phlegmasia alba dolens is usually treated by nearly all of them by rest, elevation, ichthyol, elastic bandaging, and general attention to the health and strength.

54. **Puerperal Septicemia.**—Longaker insists on the importance of early attention to the pregnant woman, insisting on careful inspection and that the keynote in the prophylaxis of infection in labor is the "touch me not" policy. He believes in the more general use of external palpation rather than internal examinations. The nurse is a very important factor in the health of the patient and a thoroughly aseptic, clean nurse is essential. All appliances must be thoroughly aseptic. He would use hot saline solution or lysol or creolin after a dry labor or an exceedingly prolonged one. The points specially deserving attention are to have the patient approach labor in good health, free from local disease, and have her surroundings clean, especially the nurse; have nothing touch her with the slightest suspicion of contamination; infrequent vaginal examinations and frequent palpation, and have nothing touch the birth canal during the early days of the puerperium—not even a sterile catheter. All the wounds occurring in the process of labor must be as carefully dealt with as less serious ones under less important circumstances.

55. **Puerperal Infection.**—Burtenshaw disbelieves in curettage of the septic uterus and has never obtained satisfactory results from uterine or vaginal tampons soaked in formalin or with alcohol, as compared with the results from iodoform gauze. In private practice he has been in the habit of introducing a suppository, containing 15 to 30 grains of iodoform, into the uterus, and packing the cavity with plain sterile gauze, repeating the procedure once or twice on succeeding days. He has never favored continuous irrigation, but he thinks it might be of benefit in putrid infection or sapremia, but not in genuine septicemia where the pathologic organisms penetrate deeply. Hysterectomy can hardly be performed early enough to be of value. A thorough evacuation of the bowels is important and the necessity of free diuresis is also apparent. In some an effective agent for this purpose is to be found in saline solutions. The use of antistreptococcic serum has been disappointing and the intravenous injection of formalin solution has met with little favor. He considers Pryor's method of opening the posterior cul-de-sac and packing the pelvic cavity with 10 per cent. iodoform gauze an excellent plan, and it is hardly necessary, he thinks, to refer to the favorable results obtained from normal salt solution injections, either hypodermically, intravenously or rectal. His experience with silver preparations has been limited. The supporting of the patient's vitality is an important factor, and attention to the diet and stimulation are necessary. The administration of drugs should be limited, but ergot, strychnin and quinin are always indicated. He thinks that an assimilable form of iodin would give good results. The patient's temperature should always be controlled by cold-water sponging and ice packs, never by drugs.

57. **Fatty Degeneration and Anemia.**—Drennan holds that fatty degeneration occurring in anemia is simply a laying-up of material for future nourishment. In the stage of fatty degeneration the anemic patient, she says, really lives on his own adipose tissue, that which is removed being replaced by more.

61 *Experience in the Medical Uses of Oxygen. C. A. Greene.
62 *A Large Dose of Chloral Hydrate. Thomas J. Acker.
63 *Present Status of the Treatment of Retro-displacements of the Uterus. Harvey P. Jack.
64 Syphilis as a Contagious and Infectious Disease. William J. Meyer.
65 Some Remarks on Hemophilia, with a Report of Cases. J. C. Hutchinson.

60. **Alcohol.**—Lambert's article is largely a critical review of the report of the Committee of Fifty on the "Physiologic Aspects of the Liquor Problem," and the monograph of Rosenfeld on the influence of alcohol on the organism. He concludes that while alcohol has a decided therapeutic value, its probable field of usefulness is more restricted than generally considered. Like all of our best remedies it is a poison, and this fact should never be forgotten.

61. **Oxygen.**—Greene finds the use of oxygen exceedingly beneficial in a number of conditions. He advises its preparation by careful washing three times through a mild solution of potash and then pure water to rid it of chlorin. He has seen the most marked favorable results from the daily use of oxygen in bronchial attacks with heavy expectoration and abrasion of the mucous lining of the larger tubes. When there is an undilatable condition of the air cells or obstruction

of the larger bronchial passages, its inhalation should be used slowly, but with persistence, retaining the oxygen as long as possible The air being entirely fresh in the inhaling room, the patient should be directed to make ten full nasal respirations between each inhalation of oxygen, breathing more deeply each time, and the oxygen breathing should be made a little more firmly and decidedly until 10 to 15 full inhalations are taken. After the air vesicles can be fairly well filled eight or ten inhalations will be sufficient at one sitting. Too much inhaling may cause cerebral hyperemia and nervous excitation and might produce hemorrhage. He also insists on nasal respiration during at least two hours of the day in the open air. In the congestion from ordinary causes and more or less severe lobar pneumonia nothing is more effective than the careful, persistent use of oxygen. He also advises it in neurasthenic conditions in sedentary persons and remarks on its value in cerebral hyperemia where there is a marked inclination to arterial or venous stasis, and especially in alcoholic and drug habitués.

62. **Chloral Hydrate Poisoning.**—Acker reports 22 drams of bromidia being taken at one dose with suicidal intent by a patient with acute mania. This dose contained 330 grains of of chloral hydrate, 330 grains of potassium bromid 2¾ grains of extract of cannabis indica and 2¾ grains of extract of hyoscyamus. The treatment was the use of tincture of nux vomica, 5 drops, a teaspoonful of brandy and half a cup of hot, strong coffee and bags of hot water applied to the extremities followed by hourly 2-drop doses of tincture of nux vomica and all the coffee the patient could swallow. In two days she had apparently recovered without any bad effects; and she was subsequently sent to an asylum.

63. **Uterine Retrodisplacements.**—Jack holds that cases should be carefully studied and that many, if seen early, can be cured without an operation by hygienic measures. That in cases where operation is required, suspension of the uterus offers the best means of cure.

67 *A New Thermophilia. Dell B. Allen.
68 Atrophic Nasal Catarrh. L. R. McCready.
69 Organic Iron Medication in Secondary Anemias. Lino S. Chibas and G. A. De Santos Saxe.

67. **A New Thermophilia.**—The organism here described by Allen is an aërobic bacillus, non-motile, non-flagellated, staining with the Loeffler and Gram solutions. It was derived from renal pus. Its peculiarity is its reaction to heat. There was no appreciable growth on bouillon at 37 C., and only a slight one on agar. It did not begin to grow freely until 60 C. Its most luxuriant growth was at 75, and at 90 it dies. There was no gas formation either before or after heating, and it is non-pathologic for guinea-pigs.

97. **The Operative Craze.**—Von Mansfelde protests against too much surgery. He thinks the surgeon should be first of all a good physician and should follow Kocher's advice and have at least two years' experience in a general hospital and ten years' private medical practice before becoming a surgical specialist.

98. **Abdominal Surgery.**—Davis points out the difficulties of diagnosis in the region of the right half of the upper abdomen, and suggests the following questions to be asked in each case: Is the lesion found capable of producing the symptoms complained of? Does it account for all the symptoms? Does any other abdominal lesion exist, and if so, what part does it play; which is primary and which is secondary? Will the surgical cure of the disease or diseases found cure the patient, and if so, what chances are there for his surviving the operation? Will the benefit overbalance the operative risks?

6 Case of Aortic Disease with Unusual Course. H. E. Bruce-Porter.
7 Case of Acromegaly. W. B. Hunter.

1. **Tuberculosis.**—This second lecture of Williams (see THE JOURNAL, April 4, 1903, p. 941) is principally devoted to the subject of cavitation of the lungs. He first describes the mechanism, which is, in the simplest form, probably due to the necrobiosis of the alveolar wall from the results of epithelial proliferation, from irritation of the tubercle bacilli, and possibly to chemical change in the cells thus produced by the germs. It is often, but not always, accompanied by fever and cough, a change in the expectoration and microscopic pieces of lung tissue are apt to be found with abundant tubercle bacilli and other organisms. The physical signs are described. When the area of softening is small the percussion sign is unchanged, but if a large cavity is formed, the dulness gives rise to limited resonance. The well-known cracked-pot sound is not an index of the size of the cavity, but indicates that it is superficial; this sound does not appear with the deeper cavities. Cough and expectoration are invariable, and yet the constitutional symptoms are not. The cavities vary not only in size and situation, but also in kind. There are the secreting cavities with smooth surfaces that look like lining membranes, but are yet exuding a great deal of matter, dry cavities with walls composed of fibroid material with little or no secretion, probably the forerunners of caseous masses composed of fibroid material, unconnected with bronchi, found in necropsies. The secreting cavities are generally found in connection with the acute forms of the disease and often extend rapidly. The dry cavity is usually the result of chronic disease and may be stationary for months or for years, causing nothing but a morning cough and expectoration. The secondary cavities are formed through the re-inhalation of secretion or sputum of primary cavities, which follow the line of certain bronchi principally where the suction power of coughing is greatest. In some patients tuberculosis is followed by so extensive an amount of excavation that the presence of air in the cavity gives rise to the phenomenon of amphoric breathing and metallic tinkling from the dropping of the fluid. The diagnosis from pneumothorax in these cases is mainly by the absence of fluid in the pleura and its characteristic signs and by the different position of the auscultation sounds. The chief signs of contraction of the cavity are the flattening of the chest wall overlying the cavity and the displacement of the neighboring organs. When the cavity is on the left side, the left lung is retracted and the right lung becomes hypertrophied and drawn across the median line. The heart is raised, its apex being tilted toward the axilla. The impulse is very slight in the chest and the stomach is drawn up. With the cavity on the right lung, corresponding symptoms occur on the other side, the left lung drawn across, the liver raised, etc. Contraction of the cavity in one lung does not prevent formation of fresh tubercle in the opposite one. It may even cause curvature of the spine. The diagnosis from bronchiectasis is based first on the age of the patient. Young adults are not so liable to the latter condition. The subjects of bronchiectasis, except when septicemic, do not show signs of wasting or anemia. Second, on appearance and examination of the sputum, which in cases of bronchiectasis is frothy, mixed with pus and more or less offensive and free from tubercle bacilli. Lastly, on the character of the cavernous sounds and their locality. Most bronchiectatic cavities are basic, while tubercle cavities are generally at the apex. The bronchiectatic cavities may, however, be detected in the first and second interspaces, where they are always nearer the median line than tubercle cavities and are never audible over such extensive surfaces of the thorax. The percussion sound is not, as a rule, dull, but resonant from the accompanying emphysema.

2. **Rheumatic Carditis and Pericarditis.**—Lees advocates the free use of the salicylates. There is only one sign that indicates danger; marked deepening of the inspiration apart from pericarditis, resembling the "air hunger" of diabetic coma. This is the only contraindication to the drug, and it should be discontinued at once. The addition of sodium bicarbonate in a quantity equal to twice that of the salicylates in each dose seems to be usually sufficient to prevent the occurrence of the symptom. The tradition that the salicylate is a cardiac depressant is discountenanced by Lees, who thinks that the heart depression is probably due to impurities in the drug and probably due still more to the disease itself. The toxin produced by the rheumatic cocci, it seems, almost certainly acts on the ventricle as does lactic acid; many earlier observers have believed that the poison of acute rheumatism is lactic acid itself. More recent observers have pointed out that the so-called *Micrococcus rheumaticus* produces formic acid in considerable quantity, and these conditions would be sufficient probably to account for the heart depression. Lees thinks that it would be better if more careful attention was paid to the condition of the heart in rheumatic cases, especially as to the size of the left ventricle in the commencing of treatment. Other methods which he mentions as of value are the application of cold, which is a powerful means of repressing cardiac inflammation and, under certain conditions, keeping the patient warm, if necessary, by hot-water bottles when an ice-bag is applied to the precordium, and keeping the warmth up during the whole period of its application, using leeches, if necessary, to prevent overdistention of the right auricle. Then the ice-bag can be used with safety in any case, however severe. Where the nursing can be thoroughly trusted an ice-bag can be used continuously for days, provided the condition of the auricle is carefully watched. He asserts that the treatment of rheumatic pericarditis by large and frequent doses of sodium salicylate and sodium bicarbonate with local application of ice over the heart is amply justified by the results, while cases inefficiently treated in the same way are likely to be slow in recovery and result in permanent crippling.

4. **Gastric Ulcer.**—Peake calls attention to two cases which indicate that certain signs are not reliable, such as the presence of shock and collapse which may be absent while regular pulse and normal temperature exist. Liver dulness and vomiting are uncertain signs, as is also pain which was present in both cases, but is sometimes apparently not observed.

5. **Tuberculosis.**—Dewar advocates the use of intravenous injections of iodoform, using it in a non-saturated ether solution. He finds that this speedily saturates the system so that even the perspiration of the palms become odorous of the drug. There is a slow sustained action which at the same time diminishes the risk of accumulative action and the patient becomes tolerant of it. It is undesirable to push the injections to the extent that the appetite is affected. The diagnostic quality of the injections is valuable. The production of fine crepitations or râles at an apex formerly dry, resonant and apparently healthy is important. Against these advantages there is the chilling effect of ether which has to be guarded against. He has noticed a breathlessness

and palpitation which he thinks may be due to iodoform. Before beginning treatment it would be well to study the available superficial venous system in the arms and legs, the more extensive this is the better the chance. While nothing is easier than to give an intravenous injection once in a large vessel, there is some difficulty in giving a hundred through a small retracted vein avoiding thrombosis and have the vessel still patent at the end of the year. Iodoform is soluble in ether in 1 to 7. He uses a not quite saturated solution, as a saturated one would evaporate too quickly and block the hypodermic syringe needle with iodoform. The solution must be introduced very slowly. He has given in some cases with very large veins as much as 45 minims at one time, but does not think such a large dose necessary. He uses the finest precipitated iodoform that can be obtained and the purest ether, specific gravity 720, making the solution fresh for each patient immediately prior to injections, exposing it to the light as little as possible. His experience is that the continuous successful injections are followed by improvement in every way except in very advanced disease where it seems to be inert in moderate doses. There is no question as to its power to arrest the disease.

15 A Brief Experience in Abdominal Surgery. B. G. A. Moynihan.

11. **The Anemias of Infancy.**—Riviere sums up the conclusions of his paper as follows:

1. Anemia from any cause in infancy if severe enough gives rise to the peculiar symptoms grouped under the headings "anemia splenica infantum" and "anemia splenica pseudoleukemica" of von Jaksch.
2. Consequently, these are not specific blood diseases, but owe their peculiarities merely to the "infancy factor," and represent merely different stages of the same conditions.
3. The common cause of severe anemia in infants is gastrointestinal catarrh, leading to the absorption of toxins either from the growth of micro-organisms or possibly from the formation of poisonous by-products of digestion.
4. Leukemia of infants is not a separate disease, but merely a still more advanced stage of this anemia—that is, that the difference between them is one of degree and not of kind.
5. That leukemia of adults is a return to the condition of an infantile anemia and that, being rare, its causation is probably so narrowed down as to be practically specific.

16. **Syphilization of the Monkey.**—Hamonic claims priority for the transmission of syphilis from man to a baboon. In 1882 his experiments resulted in the development of what were apparently syphilitic lesions twenty-eight days after the inoculation of fluid from a chancre. His communication was referred to a committee which reported that the plaster casts of the lesions were not conclusive either for or against his assumption that they were true syphilis.

17. **Infectious Angina Pectoris.**—Pawinski claims that acute infectious diseases, especially la grippe and follicular tonsillitis, are important factors in the development of angina pectoris. He admits the predisposing influence of neuropathic conditions, excesses of various kinds, getting chilled, etc. In nearly all the cases of incipient angina pectoris under his observation the effect of the toxins of the infection on the heart innervation was unmistakably evident. When the attacks of angina pectoris persist after recovery from the infection he assumes that the inner membrane of the coronary arteries has undergone certain alterations, probably in the nature of sclerosis, which entail the true angina pectoris.

18. **Appendicitis Among Non-Meat-Eaters.**—Chauvel first mentions that the number of operations on account of appendicitis in the French army has materially and progressively increased during the last few years. He then quotes the reports of physicians in Algiers and Tunis to the effect that the affection is almost unknown there. It never occurs among the Mohammedans and only exceptionally among foreigners residing there for any length of time. He queries whether this infrequency of appendicitis may not be due to the prevailing fruit and vegetable diet and the scarcity of meat. The Arabs are particularly liable to harbor intestinal parasites, and consequently the frequency of the latter with the absence of appendicitis show that there can not be the etiologic connection between them claimed by some.

25. **Experimental Tuberculosis in Java.**—De Haan was able to induce tuberculous infection in animals hitherto considered immune, the native goat, bullock and horse. The infection was realized by subcutaneous and intravenous injections of tubercle bacilli from human sputum. His experience further established that monkeys are extremely susceptible, and that the lesions resulting from the infection were localized almost exclusively in the lungs. Although the infection had been by way of the alimentary canal, no lesions could be discovered in the intestines, but the mesenteric glands in a few cases presented evidences of tuberculosis. One monkey who had eaten a potato serving as culture medium for tubercle bacilli, exhibited extensive tuberculous lesions in the bronchial glands. De Haan believes that tuberculosis in animals is always due to infection from man.

33. **Fat in the Blood.**—Rumpf has found that the proportion of fat in the blood varies essentially with the diet. It seems also to be higher in arteriosclerosis than in other conditions. Fatty infiltration of the liver is most pronounced in hard drinkers, in consumptives and in cancer subjects. As the liver shrivels under the influence of alcohol, the proportion of fat is reduced to normal or below.

34. **Preservation of Anatomic Specimens.**—The specimens are treated with carbonic acid and ammonium sulphate. A metal box one-third full of a concentrated solution of the latter is filled to a certain height with crystals of the salt, leaving 5 to 10 cm. of fluid above. The carbonic oxid is supplied in ordinary illuminating gas brought into the side of the box through a tube from a burner. It escapes through a glass tube, passing through a cork in the opening on top of the box. This escaping gas is lighted and burns with a steady flame as the gas bubbles up through the fluid in the box. The specimens

are placed on a grating below the surface of the fluid and left for forty-eight to seventy-two hours. The hemoglobin and other pigments in the tissues, especially the biliary pigments, remain unchanged in specimens treated by this method. They are kept afterward in a saturated solution of the ammonium sulphate through which gas has been passed. Claudius is delighted with the results attained with this technic.

46. Vocal Fremitus in Abdomen.—Alexander was never able to elicit the vocal fremitus in the abdomen which some writers have mentioned and cited as a sign of incipient ascites, etc.

52. Stomach Sign in Migraine and Epilepsy.—Mangelsdorf announces that he found the stomach much enlarged during attacks of migraine or epileptic seizures in 409 out of 469 persons examined. This enlargement gradually entails permanent atony of the organ. He thinks that it is of central origin. He found also that appropriate treatment of the atony of the stomach had a favorable influence on the attacks of migraine. The stomach enlarges regularly in all directions as the attack comes on, and subsides more or less completely to normal in the intervals.

56. Typhoid Fever Diagnosticum.—Ficker has coined this term to apply to a ready-made fluid with which it is possible to obtain the Widal agglutination reaction in cases of typhoid fever, without the necessity of living cultures of typhoid bacilli. The fluid keeps perfectly for nine months at least. The reaction is perceptible to the naked eye; is absolutely unmistakable, and occurs at room temperature. The practitioner is thus able to apply the agglutination test without living cultures, without an incubator and without a microscope. The results of the test are much better adapted for comparison, as the same fluid is used instead of cultures from various sources. "The fluid is derived," he says, "once from one and the same typhoid stem." Its production requires minute care and consequently Ficker has entrusted it to a manufacturing chemist who is ready to place it on the market.

57. Therapeutic Inhalation of Lime Dust.—Reckzeh's attempts in this line resulted negatively. He was induced to try inhalation of lime dust from observation of the remarkably low death rate from tuberculosis in certain villages in which there are numerous lime kilns. Another neighboring village in apparently the same condition, but without lime kilns, has twice as many deaths from tuberculosis. He also noticed that the disease was very rare among the workers at the kilns. He treated 8 patients with severe exacerbations of a mild pulmonary tuberculosis by suspending a linen bag filled with fine lime dust in front of the subjects as they lay in bed. Their ears were plugged with cotton and eyes bandaged, and the bag of lime dust was struck occasionally to stir up the dust. This treatment was given at first five and then ten minutes twice a day. No benefit was derived in any case, and the symptoms seemed to be aggravated.

60. Anesthesin Hydrochlorate for Local Anesthesia.—More than a year ago Dunbar published an account of the very successful results of local anesthesia from anesthesin injected according to the infiltration technic. His own experience since then and that of others has fully confirmed his assertions in regard to its advantages for the purpose. He uses now for operations as in mastitis, atheroma, closure of incisions, ingrowing nail, extirpation of the lachrymal sac, fissure of the lids and styes a combination of .05 gm. anesthesin hydrochlorate, and salt .2 gm. in 100 gm. distilled water. No subjective nor objective indications of irritation follow infiltration with this fluid, and the wounds heal by primary intention. In normal tissues a combination of .25 gm. anesthesin with .9 gm. salt to the 100 gm. water, causes no irritation, although it induces intense hyperemia. This proportion of salt probably has some physiologic significance. For superficial work he prefers the combination first mentioned, and for the deeper layers the proportions of .25 gm. anesthesin hydrochlorate; .15 gm. salt and 100 gm. distilled water, the latter his original solution.

61. Extension in Treatment of Fracture of Humerus.—Grässner states that 5 cases of supracondylar fracture of the humerus have been treated at Bardenheuer's clinic by extension. The results have been pre-eminently excellent as he

shows by radiograms before and after treatment. He also illustrates and describes the particulars of the technic.

63. **Appendicectomy.**—Zeller argues in favor of excision instead of resection of the appendix.

64. **Filling for Bone Defects.**—Serenin was favorably impressed with the advantages of this method of treating defects in the long bones, as set forth by Mosetig-Moorhof at the Madrid Congress. The technic has previously been described in these columns, xl, pp. 1303, 1545 and 1673. Serenin reports most gratifying success in 10 cases thus treated, including 3 of necrosis subsequent to osteomyelitis of jaw, tibia or humerus, and 7 of tuberculous lesions. The bone cavity heals rapidly under this technic, but asepsis and hemostasis must be complete, and every particle of tuberculous tissue must be removed. In 3 cases he tamponed the cavity for two or three days in order to ensure absolute hemostasis, before proceeding to fill it.

66. **To Prevent Entrance of Air During Intravenous Infusion.**—Herz gives a cut of a small appliance which has proved extremely useful in Habs' clinic. It is merely a glass tube with an extension on one side, shaped like a ball, opening into the tube with a wide orifice. The outline somewhat resembles that of the ordinary breast pump. The tube is interposed in the rubber tube leading from the receptacle for the fluid to the infusion needle. All the fluid thus has to pass through the glass tube. It is allowed to flow through at first with the bulb turned down, then the bulb side of the tube is turned upward, and the fluid is ready for the infusion. As it passes along the rubber tube from the receptacle into the glass tube, all the air in the fluid escapes through the broad mouth into the bulb on the glass tube, and none passes onward into the infusing needle.

78 Detailed Abstracts of Articles in Chrobak *Festschrift*, 1903.

68. **Relations of Functional Nervous Diseases to the Female Genitalia.**—Two addresses were delivered on this subject at the Congress, one by Krönig of Jena and one by Eulenburg of Berlin. Each discusses the subject from the standpoints of the etiology, diagnosis and treatment, and furnishes a detailed auto-abstract, impossible to condense into a few lines. Among the other communications reviewed is one by Hahn of Vienna on the great resistance of the fetus to the diseases of the mother, Veit on tuberculosis and pregnancy, and Fellner on the influence of internal diseases on the development of pregnancy, and to what extent they forbid marriage.

74. **Vaginal Operations Without Narcosis.**—Frommer advocates vaginal operating in the presence of contraindications to general narcosis, using merely suggestion and more or less infiltration anesthesia. He injects .01 gm. morphin a half hour beforehand, and finds that this aids materially in quieting the patient. She is able to advise when the uterus wall is being pushed in with danger of perforation. During narcosis the relaxed uterus is much more easily perforated. One of his 3 patients was a woman of 69 presenting prolapse of the uterus with part of the wall of the bladder and of the rectum. The second patient, a woman of 34, was operated on for vaginal rectocele, and the third, a woman of 77, for uterine cancer. In the latter case there was so little pain that the patient moaned only twice during the hour required for the total vaginal hysterectomy. Frommer thinks that injection of a weak Schleich solution into the perineum and vulva region is all that is necessary for these vaginal operations when general narcosis is contraindicated for any cause. Gradenwitz has reported 3 cases of total vaginal extirpation of the uterus without narcosis. Asch advocates refraining from general narcosis during curettement of the uterus, and Kleinhaus has recently expatiated on the advantages of restricting narcosis in favor of infiltration anesthesia in vaginal plastic operations and simple celiotomy.

90 *New Method of Diagnosing Fracture of Bones. Plesch (Ofen Pest).—Eine neue Methode zur Diagnostizierung der Knochenbrüche.

81. **Acoin in Surgery.**—Daconto recommends in place of cocain a 1 per cent. solution of acoin with .8 per cent. sodium chlorid.

82. **Iodized Catgut.**—Claudius reaffirms the superiority of catgut prepared according to his method—placed for eight days in a solution of iodin, after which it is ready for use. Just before using it is rinsed in a 3 per cent. solution of carbolic acid.

83. **Injury of Epigastric Vessels During Puncture.**—Symptoms of ileus developed after puncture for relief of ascites in the case described. A large tumor formed at the point of the puncture and an incision released a quantity of blood clots and disclosed that the epigastric artery had been injured. It was ligated and the patient recovered promptly. In similar cases on record the epigastric had bled always into the abdominal cavity.

85. **Incarcerated Hernia.**—In this report of 175 cases of incarcerated hernia it is stated that 8 out of the 14 cases of umbilical hernia terminated fatally. Out of the total 175 patients 38 had previously worn a truss which shows that a truss does not guarantee against incarceration. These experiences indicate that it is a much safer plan to bring out and keep the intestine outside the abdominal cavity when there is any question as to its vitality. Of the 35 fatal cases, 28 were due to peritonitis.

87. **Spiral Fractures.**—Bayer states that out of the 2,332 cases of fracture treated at the Cologne public hospital during the last three or four years 75 were spiral fractures below the knee. He advocates Bardenheuer's extension for all such cases and describes the technic in detail. Consolidation was complete in thirty-three days on an average.

88. **Arrosion Hemorrhage After Tracheotomy.**—Martina's 2 cases were both in women, 27 and 42 years old. The tracheotomy had been done on account of tuberculosis or carcinoma and the fatal hemorrhage occurred the eighth and twelfth day after the operation and insertion of the canula which had caused the decubitus.

89. **Tardy Affections After Skull Injuries.**—Colley's patient exhibited visual disturbances three months after an injury to the head, and two years later violent neuralgia of the right frontal nerve. The visual field was reduced to 1/12 and the right frontal nerve was much enlarged. There was also slight paresis of the internal rectus. After resection of the frontal nerve the neuralgia subsided. He is inclined to attribute the

visual disturbances to traumatic injury of the region of the fourth ventricle and corpora quadrigemina.

90. **Diagnosis of Fractures by Sound Conduction.**—Plesch diagnoses fractures in the bones by percussion and auscultation. The normal conduction of the sound stops at the point of the fracture.

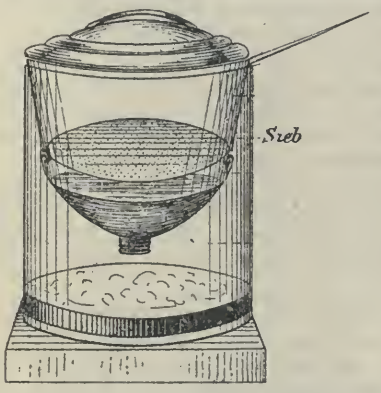
99 From the Washington Congress of Physicians and Surgeons. C. Beck (New York).—Vom 5 Kongress der amerikanischen Aerzte und Wundärtze in Washington.

91. **Etiology of Pancreas Necrosis.**—Hess reports a series of experiments conducted at Marburg which demonstrated that fat injected into the pancreas through the efferent ducts caused total necrosis of the organ, with hemorrhage, fatty degeneration and rapid death, the symptom complex resembling in every particular, both clinical and in the pathologic anatomy, that of pancreas apoplexy in man. Glycerin and starch had no such effect as the olive oil and oleic acid, and paraffin induced only mechanical lesions. After discussing various theories to explain this rapidly fatal action, he suggests that the oil may possibly induce a saponification, and the symptoms be due to a soap intoxication. Münk's researches have shown that intravenous injection of .1 gm. of soap per kilogram will kill animals with symptoms of collapse, fibrillary contractions, etc.



92. **Lacerations of Vagina and Pelvic Floor Cause of Prolapse.**—Schatz thinks that more attention should be paid by accoucheurs to preservation of the integrity of the vagina and muscular floor of the pelvis. The abdominal bandage favors laceration of the vagina, and the obstetrician is also frequently responsible for it, especially by early application of the forceps and extraction in breech presentation. The primipara should be preserved from breech presentation on this account. The obstetrician is too apt to devote all his attention to preserving the perineum, while this is comparatively unimportant; it has nothing to do with the integrity of the pelvic lumen, which lies on a higher plane. In order to exercise the pelvic floor, Schatz has his parturient patients after the tenth day and women with descensus sit on a chair which has a knob 5 cm. high in the seat. This knob presses the relaxed pelvic floor into place and helps the women to exercise the muscular floor of the pelvis energetically and repeatedly. The tendency of the fetal head to drag the walls of the vagina along with it is counteracted by the contractions of the uterus, which pull up the collum and vaginal walls. This tendency on the part of Nature is sometimes nullified by the "bearing down," the straining of the woman who does not allow the uterus time for its contractions, and actually forces the walls of the vagina farther and farther downward, with laceration as the inevitable result. This frequently occurs in young, healthy women, and the muscular floor above usually tears with the vaginal walls. The levator ani is particularly liable to be torn from its attachment, as it has to stand the greatest strain. Unless it can be restored to its place and fastened there, the loss of its support invites prolapse and descensus, especially after later pregnancies. It is a difficult matter to discover and remedy these lacerations in the pelvic floor and vagina. From his experience in such cases Schatz now prefers prophylactic measures, and when these lacerations are imminent he makes a deep incision on the left of the vulva to preserve the perineum and then carries this incision further upward until it forms a complete paraproctal incision of the vagina to at least half its height and sometimes still higher. When incised in this way it is impossible for the vagina to tear along the side and be torn from the arcus tendineus, thus preventing laceration of the levator ani, at least from its point of attachment. It is much easier to suture this single paraproctal incision than to take care of the multiple lacerations and detachments liable without it. This paraproctal incision differs from Dührssen's vaginal cesarean section, as it never extends into the upper third of the vagina and involves only the soft parts of the pelvic floor. It is made on one side only and presents a clean and easily sutured wound—far preferable to the conditions liable without it. It is readily sutured with the aid of fixation forceps, which the obstetric nurse can easily manage alone. In conclusion, Schatz remarks that it is absurd to assume that any practitioner is able to handle all obstetric cases properly. Obstetrics is an art when correctly practiced, and prolapse will become less and less frequent when this is recognized and primiparæ are delivered in equipped establishments.

93. **Recent Laceration of Perineum.**—Hegar protests against the assumption that it is wise always to suture a laceration in the perineum immediately after delivery. He thinks that the suture should be undertaken at once in case the condition of the wound insures primary healing or at least renders it highly probable, if the laceration be not too extensive, not extending too far in the rectovaginal septum, and the tissues have not been crushed and there is no suggillation. The general condition of the patient must also be good and the resisting powers to be counted on. Already existing infection must be positively excluded, with no evidences of fever or discharge suggesting endometritis or colpitis. Finally, the environment must be such as to ensure all aseptic and antiseptic precautions and a favorable convalescence free from infection later. Under other conditions the suture of the tear should be postponed until after recovery. It is liable to heal spontaneously. In 53 cases in his experience treated expectantly, the lacerations of the first and second degree healed by primary intention in 33.9 per cent., with exact coaptation of the lips of the wound. In 11 cases the lips of the wound healed, but not in perfect position, and in 11 cases there was partial primary healing. In 77.3 per cent. of all the cases the functional results of the spontaneous healing were excellent. Only one of the 53 had any temperature. On the other hand, the statistics at Chrobak's clinic show some temperature in 95 out of 1,036 parturients not examined before the birth. In 45 cases in which suture was not attempted, the fever was slight in 86.6 per cent. and severe in 13.3 per cent. In 50 cases in which the laceration had been sutured the fever was severe in 38 per cent. of the cases—and this in a well-managed clinic. The proportion would certainly have been larger in private practice. Hegar cites other statistics to sustain his plea that immediate suture of the laceration in the debilitated condition of the patient affords a predisposing soil for development of germs in the secretions pent in by the suture. In his clinic parturients after delivery with a laceration have a bandage wound around the legs above the knee and are kept in the strictest dorsal decubitus for eight days. Douches and other manipulations are done with the greatest care during this interval, and entrusted only to exceptionally skilled attendants.

94. **Immunization with Ovarian Extract.**—The research described was undertaken to establish the cytotoxic power of the serum of small animals previously treated with extract of the ovary or corpus luteum. Among the points determined was that the immune serum had a favorable action on the spermatozoa of animals of the species from which the extract had been derived. In ordinary serum the spermatozoa soon lose their motility while in the immune serum they retained it for an exceptionally long time.

97. **Sieve for Feces.**—Schilling's sieve is free from the objections of most articles of the kind he states. The feces placed

in it automatically cleanse themselves and the residuum is free from odor. The apparatus is extremely simple and does not require running water, but can be set aside in a closet to do its work. Fitting into a large glass jar is a second glass vessel with a brass sieve a short distance above the bottom which tapers to a small opening below, closed with a screw cap. (See cut.) After the feces are placed on the sieve, water is poured on until it rises above the feces which thus float on the water until the latter subsides as it escapes

a drop at a time through the cap below. After six to eight hours the residuum left on the sieve can be examined without offending the eye or nose. Schilling has already made some interesting discoveries with the residuum thus conveniently obtained, and refutes the assertions of Voit and Schmidt in regard to the digestive powers of dogs.

114 *Treatment of Acute Nephritis with Ice. L. Stembo (Wilna).—Behandlung der akuten Nierenentzundung mit Eis.

107. **Treatment of Exophthalmic Goiter.**—Kirnberger has found that patients with exophthalmic goiter increased in weight under the administration of 10 gm. a day of sodium sulphanilic acid (sulfanilsaure Natron). He uses it on account of its being an antidote to iodin. The pulse was regulated by this drug, but the goiter and tremor were not always influenced. In one case he alternated it with rodagen. The goiter subsided and the pulse was reduced from 140 to 80. In another case this medication was kept up for two years. The mother of this patient was also a typical case of the disease.

108. **Thiosinamin.**—Lewandowski proclaims that thiosinamin is harmless and will be found particularly useful as a preliminary to operations in which adhesions are feared. Also in case of cicatricial conditions on the surface of the body or in the interior. It is liable to cure disturbances due to cicatricial contracture and is also effectual in hastening absorption of old opacities on the cornea, in cataract, iritic adhesions, choroiditis disseminata with exudation, and in deafness due to fibrous masses and cicatricial changes in the inner ear. His experience indicates that it should not be used when there might be danger from the flaring up of a subsiding process, as in recent keratitis. He injects a 15 per cent. alcoholic solution, preferably in the forearm under the skin.

113. **Erysipelas.**—Pollatschek reviews his experience with 300 cases of erysipelas, 14 fatal. He treated 33 of the patients with red light, 12 with collargol, others with mesotan, etc., but found that his mainstay was the application of icecold compresses wet with Burow's solution. The results were much better in the 80 cases thus treated than in the others. In case of much pain he supplements it with a 10 per cent. salve of anesthesin, and in extremely severe cases with intravenous injection of collargol.

114. **Treatment of Nephritis with Ice.**—Stembo has treated 20 patients with acute nephritis by application of ice bags to both kidneys, held in place with a bandage. After two or three hours he removes the ice for an hour and then replaces it, keeping up this treatment until the albuminuria has entirely vanished. This ice treatment is especially useful in sudden, acute cases of nephritis and in the acute exacerbations of a chronic affection.

115. **Two Unusual Uterine Growths.**—Opitz describes a mixed tumor, a combination of adeno-carcinoma and sarcoma, removed from a woman aged 57. The mucosa of the corpus was the starting point. All the cases on record similar to this were in women at the climacteric age. The growth was comparatively benign and the sarcoma was polypous, consisting partly of round and partly of spindle cells. He suggests the possibility that the same cause may incite the epithelium to carcinomatous proliferation and the connective tissue to sarcomatous. If this prove to be true, then carcinoma and sarcoma may be considered identical from the etiologic standpoint. In the second case described, a mucous polyp removed from the vagina proved to be carcinomatous. The pedicle of the polyp sprang from the tubal corner and an epithelioma had developed on it. He can not find in the literature another case similar to this.

116. **Endothelioma Cervicis.**—Kirchgessner adds one more to the 12 cases of endothelioma uteri on record, bringing the number of those located in the cervix up to 9. The patient

was a iii-para, 34 years old. The tumor was located in the anterior portion of the cervix and the patient succumbed to peritonitis after total extirpation. Out of the total of 9 cases only 2 recovered after vaginal hysterectomy. The growth in the case described may be entitled an endothelioma lymphaticum cervicis uteri.

118. **Syncytiolysis and Hemolysis.**—The side-chain theory and the knowledge that the elements of the fetus may be deported into the maternal organism are illuminating the questions of the physiology and pathology of pregnancy. Scholten discusses them at length, laying particular stress on the significant clinical observation that in eclampsia and "pregnancy kidney" hemoglobinuria is not an infrequent occurrence. His therapeutic application of this new knowledge is proving very promising, he states, and he will publish the results soon.

119. **Etiology of Ovarian Adenomata.**—Walthard's extensive article is an important contribution to the anatomy and histology of the ovaries. It is based on systematic examination of 80 ovaries from women and girls of various ages.

120. **Myoma Operations.**—In 58 out of the total 150 cases reviewed, the myoma was removed by the vagina and in 82 by the abdominal route. The total mortality was 12 per cent. There were no fatalities in 15 conservative abdominal operations. Czempin reviews the technic followed in the different groups of cases.

121. **Syncytioma Malignum.**—Schmauch does not regard a pregnancy as indispensable to the development of a tumor of this character; it may originate from aberrant fetal cells. He does not consider the syncytium as a specific variety of cell, but believes that it is merely one phase in the cell life of the Langhans epithelium cell. The preliminary to the syncytioma is the existence of syncytial "wander cells" in the tissues. He describes a case of hemorrhage three weeks after delivery of a living child, the woman a robust iv-para. She died in the course of seven weeks notwithstanding operative measures. The necropsy revealed numerous syncytioma metastases throughout the vagina, kidneys, lungs, spleen and brain, but no primary tumor could be discovered. He consequently argues that the syncytioma belongs in the teratoma class. During the pregnancy the syncytioma checks or prevents the normal formation of syncytiolysins according to the side-chain theory. This suggests the possibility that such conditions might be combated by immunization measures if surgical intervention offers no prospects of success.

129. **Influence of Lactation on Conception.**—Weinberg states that conception occurred during the first six months after childbirth in only 12 per 1,000 of 513 non-menstruating women who were nursing their children. The proportion rose to 595 per 1,000 in 615 women who were not nursing children. The influence of lactation on conception is thus confirmed.

132. **Hereditary Tendency to Multiple Births.**—Rosenfeld's statistics are based on the family history of 216 families among the German nobility. An inherited *Anlage* to multiple births is unmistakably shown in a number of them, and also the fact that this tendency is an evidence of greater fruitfulness. An accumulation of twin births among those most closely related is the rule.

133. **Angioma of Placenta.**—Krauss describes the varieties of this growth as he has observed them in 6 cases.

134. **Repeated Childbirths in Women with Contracted Peives.**—The prognosis of the childbirth may be established by what occurred during the last delivery, as each deformed pelvis has its own particular mechanism of childbirth. Sixty-six women with conj. diag. of 7.5 to 11 cm. had children delivered at the Berlin clinic three or more times, a total of 286 births. Henkel found it indispensable to determine the position of the skull in respect to the pelvis for each individual case. A repetition of cesarean section may be advisable and offers a good prognosis.

135. **Solitary Hematocele.**—Alterthum reports a case and reviews the literature. The capsule of the hematocele after a tubal abortion was formed at first of fibrin, but as adhesions developed the capsule became at last a complete envelope of connective tissue.

136. **Transverse Septum in Vagina.**—Brickner does not think that this condition in unmarried women calls for treatment, but the septum should be excised as soon as a pregnancy is suspected. Intrapartum an *X*-incision is sufficient. The prognosis is bad for the child unless the septum is recognized and removed in time. The mother is likewise liable to lacerations or fatal hemorrhage on the same account. He reports 4 cases with 9 cuts.

137. **Influence of Poisons on Gaseous Interchanges.**—A number of tests on animals with strychnin, digitalin, etc., are described in which particular attention was paid to study of the gaseous interchanges. The results show the importance of regarding this effect of poisons in estimating their action on the organism. Also that the antagonism between certain poisons may be due to the opposite effect on the intake and consumption of oxygen, etc.

138. **Soluble Glass for Injecting Anatomic Specimens.**—Of all the materials used for injecting blood vessels, a saturated solution of potassium silicate has proved the most perfect for the purpose in this writer's experience. He adds a little prepared chalk previously tinted red or blue. This helps to solidify the mass which he prepares fresh, keeping the ingredients separate until needed.

139. **Surgical Scarlatina.**—Forty-four patients out of 2,000 operated on at the Children's Hospital, St. Petersburg, between 1897 and 1902, developed afterward the so-called surgical scarlatina. The infection coincides with the trauma of the surgical intervention. This form of scarlatina is marked by the short period of incubation, the initial fever, the rash and desquamation around the wound, complications on the part of the wound and, finally, by the absence of the specific scarlet fever sore throat. Scarlet fever is classed by the writer as a wound infection liable to complicate any operation or wound the same as erysipelas, tetanus, etc. He believes that many cases of the so-called erythem following the use of diphtheria antitoxin should probably be regarded as surgical scarlatina. The article concludes with the bibliography on the subject, after presenting in an elaborate table the details of 36 of the cases of surgical scarlatina on which the work is based. The period of incubation was less than twenty-four hours in 8 cases; less than three days in 13; less than five days in 5, and from twelve to sixty-six days in the remainder. The course of the affection is mild, and none of the three deaths in the series could possibly be attributed to it.

141. **Breaking Open of Laparotomy Wounds.**—The stress under which the wound broke open in the 26 cases reviewed was due to coughing, vomiting, excessive exertion, trauma-

tism, etc., nearly all mechanical. The list includes 2 personally observed. Orloff concludes that such a wound should be protected better than is the custom until it has solidly healed, meteorism should be prevented, and all possible sources of mechanical injury avoided.

143. **Cryoscopy of Urine in Children.**—Hindes reports his findings in a number of examinations of the urine of children both in health and in nephritis, and on a meat or milk diet. His conclusions are that this method of examination is too variable in its results when applied to the urine of children, at least, and that its findings can not be relied on with any accuracy.

145. **Neuropathic Spondylitis.**—This comprehensive communication from Bechtereff's clinic reports in detail a number of cases, concluding with a review of the literature on the subject of chronic ankylosing inflammation of the spine. Troshin distinguishes the Bechtereff type as a neuropathic curvature of the spine, while the Strümpell-Marie type is more in the nature of arthritis deformans. In the latter the changes in the spinal cord are similar to what is observed in arthritis deformans and it should be regarded consequently as a trophoneurosis. Generally speaking, all the various forms of spondylitis may be considered functional affections free from inflammatory processes. The special features of each type vary with the fundamental cause of the spondylitis.

147. **Experimental Study of Decapsulation of the Kidneys.**—The researches described failed to show any benefit from decapsulation in experimental kidney affections. There was no reformation of vessels, and merely proliferation of connective tissue and atrophy of the exposed parts.

152. **Albuminuria.**—Cloetta has been studying the three forms in which albumin may appear in the urine. The amount of serum albumin and serum globulin is far superior to that of the nucleo-albumin form and hence the latter may usually be neglected where extreme accuracy is not necessary. He designates the figure obtained by dividing the serum albumin by the globulin as the albumin quotient, and states that the acuter the nephritis, the smaller this quotient and the larger the proportion of nucleo-albumin. In chronic nephritis with induration, serum albumin predominates. He believes that the condition of the renal parenchyma determines the albumin quotient in the urine. The acuter the nephritis, the severer the lesions in the parenchyma, rendering it more permeable for the substances in the blood. The quotient in this case is nearly identical with that of the blood serum. The tougher the parenchyma becomes by indurative processes, the less permeable and the more effectually it retains the globulin. The nucleo-albumin does not seem to be derived from the blood, and is probably due to destruction of kidney cells. Whenever a chronic process undergoes an exacerbation there is renewed destruction of cells and hence increased output of the nucleo-albumin which thus acquires prognostic significance. Comparison of the albumin output with the findings of the freezing-point test shows that there is no direct connection between them. The absolute amount of albumin eliminated is not proportional to the functional disturbance in the kidney evidenced by the variations in the freezing-point. On the other hand, there seems to be a direct proportion between the amount of substances precipitated by acetic acid and the functional disturbances. In his experiments on rabbits he observed that the elimination of the albumin entirely ceased during the course of an acute nephritis, while the molecular concentration did not show any signs of decrease, but rather increased, and this combination was always followed by speedy death. In such cases we must assume that notwithstanding the tendency to anatomic healing, the kidney is not capable of rallying from its functional disturbance and the individual succumbs to the effects of the nephrogenic intoxication. This assumption that the anatomic lesions and the functional disturbances are not necessarily proportional, was confirmed by the results of administration of various drugs which have a toxic action on the kidneys. Cantharidin seemed to have less influence on the vital activity of the kidney cells than aloin, although the anatomic lesions were apparently identical. It is possible that in man cases of nephritis which seem clinically and in their pathologic anatomy to be identical may yet differ as widely as in the aloin and cantharidin experimental tests. This difference may be due, as in the latter, to the varying intensity of the functional disturbances, which in turn are dependent on the nature of the toxin causing the trouble.

AN EPIDEMIC OF TYPHOID FEVER FROM SEWAGE POLLUTION OF CITY WATER SUPPLY.

THOMAS F. HARRINGTON, M.D.

LOWELL, MASS.

Typhoid fever is such a widespread and universal disease that any observation tending to show its origin or mode of conveyance has more than ordinary interest. Drinking water has long been suspected as one of the media by which typhoid bacilli enter the body, and there set up their characteristic sequelæ. This suspicion has been more or less strengthened from time to time by epidemics in which there was considerable probability that an infected water supply was the means by which cases of typhoid fever multiplied. In the epidemic of typhoid fever, which forms the basis of this paper, a chain of evidence of cause and effect is so complete that it is worthy of presentation. In order that the whole situation may be as clear as possible it will be necessary to relate what might be called a history of the water supply.

Lowell, Mass., is a manufacturing city of about 100,000 population, situated on the Merrimac River between Manchester, N. H., and Lawrence, Mass. Both of these cities are mentioned, as reference is to be made to the typhoid fever cases in each. Prior to 1893 all the water furnished, both for drinking purposes as well as that used for domestic and manufacturing purposes, was taken from the Merrimac River, the result being that Lowell experienced an epidemic of typhoid fever whenever Manchester increased the river pollution by sewage from an unusual number of typhoid cases. This is best shown by the appended table:

TABLE I.

	Cases.	Deaths.
1890	459	123
1891	293	77
1892	373	75
1893	160	53
1894	282	50
1895	172	33
1896	178	36
1897	105	18
1898	119	24
1899	57	17
1900	85	17
1901	70	18
1902	83	16

The above table represents a reduction in the death rate from 1.58 per 1,000 inhabitants to .11 in thirteen years. Lowell in its turn transmitted the disease to Lawrence until the latter saw the folly of continuing the use of polluted river water and substituted filtered water for drinking purposes. In 1893 Lowell introduced a system of driven wells for the supply of city water.

This system was further extended in 1894-95 and in 1896, when all connections with Merrimac River water were severed, and the total daily consumption taken from the driven wells. The manufacturing companies did not partake of this new water supply, but continued to maintain an independent system, consisting of Merrimac River water pumped into a private reservoir to be used for fire purposes and a second supply pumped directly from the canals into the supply pipes in the mills. This latter is also Merrimac River water and is used for manufacturing and sanitary purposes. Some of the mills have made connections with the city system, but the large majority use only Merrimac River water, and as this is furnished at the sinks there is more or less use of it by the operatives for drinking purposes. Each sink has a large placard marked "poison" over the faucets, and the operatives are forbidden to use the water for drinking. Although many of the mills send boys with pails to wells in the neighborhood for drinking water, nevertheless cases of typhoid fever are constantly occurring among operatives in which the use of canal water is the most likely mode of infection. There are approximately 20,000 operatives in the mills. The corporation reservoir supplying the mills is situated thirty feet higher than the city reservoir supplying the same districts with well water for all purposes. These two systems are separated at a point of intersection by a check valve, and this was thought to be sufficient protection against the possibility of any intermingling of the two. The check valve is composed of four "flappers" which close automatically and remain closed on account of the greater pressure in the corporation system than that in the city system. In the event of fire, demanding any unusual supply of water from the corporation system, the valve opens as soon as this demand so lowers the pressure that the pressure in the city supply exceeds that in the other; in this way the city supply would reinforce the corporation supply. When the latter recovered its loss its increased pressure closes the valve again, and two systems remain separated as before.

PRESENT EPIDEMIC.

On the evening of Saturday, July 18, 1903, a large fire occurred in the Merrimac manufacturing mills, which drew heavily on the water supply from the corporation reservoir, sufficient to allow the check valve to open in the manner described above. The fire lasted from 8 p. m. Saturday to 2 a. m. Sunday, after which time steps were immediately taken to replenish the low supply of the reservoir. To do this water is usually pumped from one of the wheel pits at the Lawrence manufacturing mills, or from one of the other canals. The canals had been drawn off Saturday afternoon, as

is the custom at certain times of the year, and the river near the opening leading to the wheel pit was very low on this particular day. About 550 feet from this entrance to the wheel pit is an outlet of one of the city's sewers emptying into the river; consequently the sewage must have been sucked into the pit, and from there pumped to fill the reservoir. This is well shown by the accompanying diagram:

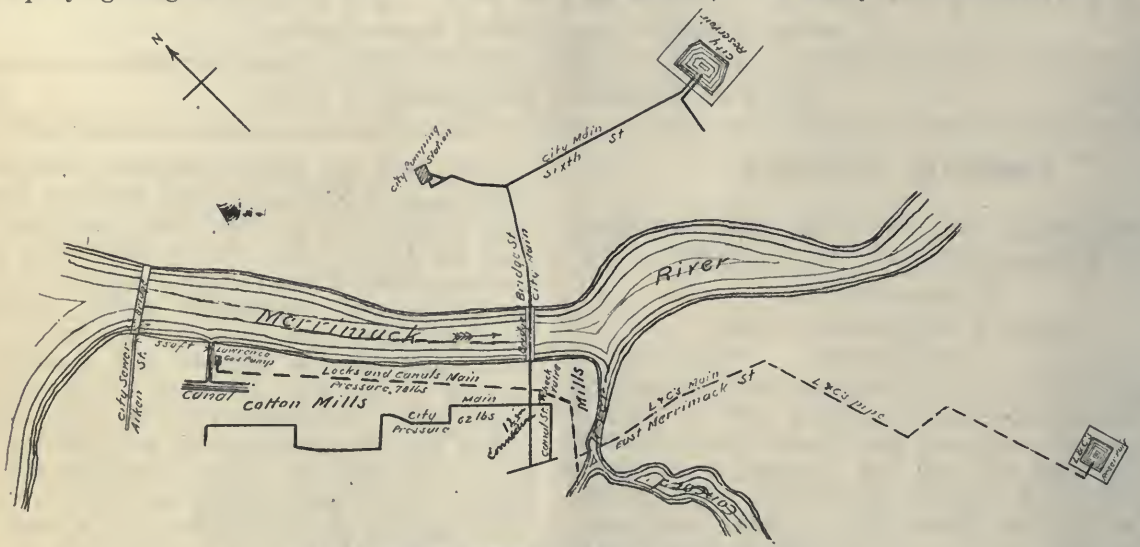

Fig. 1.—Sketch showing location of open check valve.

Seven hours later (9 a. m.) it was discovered that little or no headway was being made in refilling the reservoir. This led to an investigation which revealed the fact that the check valve described above, separating the city supply and the corporation supply, did not close when the increased pressure was applied; thus the sewage contaminated water was being driven directly into the city mains, there mixing with the driven well supply. From the point at which intermingling took place the water naturally was driven in those directions in which there was the least resistance, i. e., where water was being used, and also in a direction most direct from the break in the current, consequently any ill effects from the contamination of the water would show itself in the localities thus supplied. On account of the time of the day as well as the day of the week (Sunday) the consumption of city water was at its lowest point, thus giving the polluted water a much wider range of distribution than would otherwise have been possible. In two days after the above-described occurrence the number of cases of enteritis and gastro-enteritis was so great that it was plainly evident that an infection of some sort had taken place. These cases were principally among adults and were not associated with any climatic change. Their distribution was such that there was but one common cause probable, namely, drinking water. Families living in districts supplied with water from the high pressure (city) service were not affected, while nearly all the cases occurred on the low service separated from the corporation system by the check valve. No suspicion could be attached to either the milk or ice supply.

There had been four cases of typhoid reported to the health department during July. About August 1 cases of typhoid fever began to be reported with alarming frequency. One hundred and thirty-six cases were reported during August, and 38 during September. These cases were reported weekly as follows:

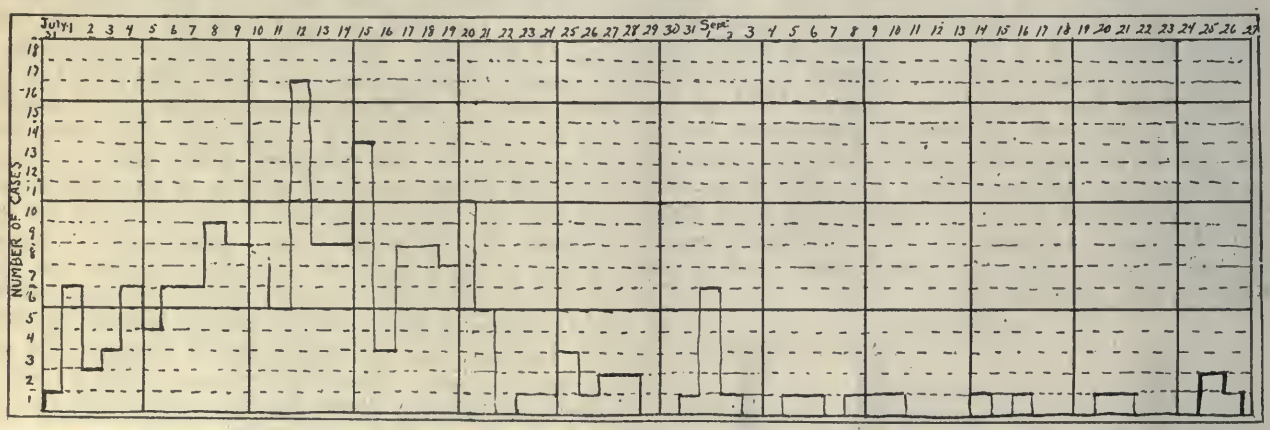

Chart showing the dates on which the cases went to bed. (The fire occurred July 18. The first cases appeared about July 31.)

TABLE II.

	Cases.	Deaths.
August 1 to 8	0	0
August 8 to 15	13	0
August 15 to 22	75	1
August 22 to 29	41	1
August 29 to September 5	20	2
September 5 to 12	7	2
September 12 to 19	8	2
September 19 to 26	4	0
September 26 to October 3	4	1

Many of the cases reported as typhoid in August and September came from families or houses in which there had been cases of enteritis during the period July 19 to August 1, some members of the family recovering fully from the acute enteritis, while others went on to a

well-developed typhoid. The accompanying interesting chart, prepared by Dr. Frank L. Morse of the Massachusetts State Board of Health, shows the dates on which the several cases of typhoid fever became ill enough to go to bed, thus differing from Table II, which shows the dates on which the cases were reported to the health department.

No bacteriologic examination of the city's drinking water was made between the dates July 19 and 29. On the later date the city's supply pipes were thoroughly flushed; this reduced the possibility of finding traces of the supposed contamination to a minimum. It was estimated by the water department that about 500,000 gallons of sewage or Merrimac River water found its way into the city's water service between the hours of 2 a. m. and 9 a. m. July 19, before the defective valve was discovered. This amount is equivalent to about one-twelfth the average daily consumption of city water. There is no way of estimating how long before 2 a. m. the two systems had been in communication. On July 29 (ten days after the contamination) the State Board of Health made a bacteriologic examination of the water. The following report, which I am permitted to publish through the kindness of the water department, explains the findings of that examination:

OFFICE OF THE STATE BOARD OF HEALTH.

BOSTON, Aug. 26, 1903.

To the Lowell Water Board, Lowell Mass.

Gentlemen:—In response to your request of July 28 for bacterial examination of the water supply of the city of Lowell, the board caused samples to be collected from various parts of the city on July 29 and again on July 31, and sends you herewith the results.

The average number of bacteria found in different parts of the city on July 29 was 17, which is nearly the same as the number found at the force-main at the boulevard wells, indicating no added pollution at this time. This number is smaller than the average found in other driven well supplies throughout the state.

On examining these bacteria to learn if *Bacillus coli*, which is regarded as indicative of pollution by sewage, was present, none was found in any of the samples when the usual amount of one cubic centimeter was examined, but on examining one hundred times this amount this species was indicated in two samples, viz.: one taken from a store in Pawtucketville and one taken from Walker street. In both these cases the whole number of bacteria was unusually small, averaging but ten, indicating a small degree of pollution.

Another series of samples taken on July 31 gave somewhat higher number of bacteria present, but no greater increase than might be expected from the temporary effect of the flushing out of the city mains on July 29 after the collection of the first series. By this flushing and the subsequent filling the sediment remaining in the mains was probably stirred up, and the bacteria in this sediment and on the sides of the pipes were detached.

The number of bacteria in all of these samples averaged as low as in other driven well supplies of the state, but the presence of *Bacillus coli*, even in small numbers, was an unusual occurrence. With the first four samples of the second series all of the bacteria in 1,000 c.c. were also examined with no indication of *Bacillus coli*.

(Signed) SAMUEL W. ABBOTT, Secretary.

The water supply from this source had been regularly examined and had never shown the presence of the *Bacillus coli*.

TYPE OF THE EPIDEMIC.

As a whole, the disease was of a mild character, the death rate being 4.4 per cent. The city bacteriologist, in a personal letter to the writer, says: "The unusual increase in the number of cases of typhoid fever was noticed about August 1. Counting from that date to the end of September, 90 specimens of blood were received here. Of these 58 were positive, 25 were negative, 7 unsatisfactory for various reasons. In some of these the examination was repeated twice or three times before getting a positive result." Cases at the hospitals (about 50) were verified there, consequently do not figure in the above report. From a study of about seventy-five cases of the epidemic, seen at the hospitals and in private practice, the following characteristics prevailed: Onset sudden and often accompanied by a chill; temperature high at the start (102 to 104) and remaining high well into the third week; pulse slow and not in proportion to the temperature, being more often under 100 than over; diarrhea present in 55 per cent. of these cases; rose spots present in 80 per cent., and diazo-reaction positive in 90 per cent. of all cases, giving a positive Widal test; nose bleed absent in 90 per cent. of all the cases; the average duration of the fever was twenty-seven days, with a slow convalescence. Among the complications occurring the following were the most marked: Phlebitis in 8 cases, bronchitis in 6 cases, otitis in 4 cases, arthritis in 4 cases, neuritis in 2 cases, acute mania in 1 case, edema of the lungs 1 case, endocarditis 1 case (death). There were 8 cases of intestinal hemorrhage, 1 with a second hemorrhage. None of these died.

There were several cases in which the clinical picture of typhoid fever was not substantiated by a positive Widal test. These cases did not have rose spots nor an enlarged spleen. The complications mentioned above were as frequent in this class of cases as in the genuine typhoid. There were no means at hand to prove whether these belonged to the paratyphoid group, although this clinical diagnosis seemed well established.

I desire to acknowledge my indebtedness to the Massachusetts State Board of Health and to the Lowell water and health departments for their kindness in furnishing me with the results of their respective investigations.

THE UNITED STATES PHARMACOPEIA OF 1900.*

CARL S. N. HALLBERG, PH.G.
Member of the Committee of Revision.
CHICAGO.

The revision of the Pharmacopeia begun by the committee elected at the decennial convention in Washington, in 1900, is progressing as rapidly as is warranted by the importance and magnitude of the work.

The committee lost its chairman in 1901, Dr. Charles Rice, pharmacist to the Department of Public Charities and Corrections of New York, who had filled that position with especial credit since 1880, and suffered further loss in the death of a life-long worker, Dr. Edward R. Squibb of Brooklyn. The death of the chairman at a critical point of the work caused some delay until the vacancy was filled by Prof. Joseph P. Remington of Philadelphia. Partly due to this fact, but more especially owing to the many important questions, never before confronting a committee of revision, requiring solu-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. S. Solis-Cohen, George F. Butler and N. S. Davis, Jr.

tion, the work of revision has been more than usually delayed so that the book will in all probability not appear until in 1904. The official life of the U. S. Pharmacopeia will, therefore, not be synchronous with its decennial designation (1900-1910), which, however, is not of any especial significance.

THE SUBCOMMITTEES.

As an indication of the scope and character of the work of revision the enumeration of the following subcommittees and the subject allotted to each may be of interest:

1. Therapeutics.
2. Posology.
3. Botany and pharmacognosy.
4. General and inorganic chemistry.
5. Organic chemistry; also fixed oils and fats.
6. Proximate assays.
7. Volatile oils and allied substances.
8. Extracts, tinctures, etc.
9. Aromatic waters and spirits.
10. Cerates and allied compounds.
11. Syrups and elixirs.
12. Miscellaneous galenicals.
13. Weights and measures.
14. Scope and statistics.
15. Nomenclature.

LIMITATION OF PURITY.

Among the most important subjects for consideration, and one which heretofore has received but little attention, was the limitation of purity of medicinal chemicals. To the medical mind, the propriety of this question may well appear doubtful. Why should there be any limitation? Only the purest is sufficient for medicinal uses, or for the purposes of the physician. The proposition is, however, not so simple, since there are certain requirements of a practical character which must be taken into consideration. The U. S. Pharmacopeia (1890), now official, requires for a number of largely used chemicals a greater degree of purity than is obtainable by ordinary chemical processes, a standard—as is claimed by reputable manufacturers—to be obtained only by such expensive processes as to necessarily increase the cost of the product, and as to be in some instances almost prohibitive.

It should be clearly understood, however, that these impurities comprise mostly the presence of very small quantities, sometimes 1 per cent. or less, of sulphates and chlorids in bromids, iodids, phosphates and similar salts, the contention on the part of manufacturers being that the removal of such traces of these foreign salts would be exceedingly difficult, and since their presence could have no possible therapeutic significance, their absolute removal would be a useless expenditure.

Some instances were cited in support of the contention that the presence of even slight traces of foreign salts, innocuous of themselves, might under certain conditions produce entirely unexpected results; thus, for example, when potassium bromid is prescribed with barium chlorid in watery solution, there will be a precipitate of the insoluble barium sulphate in the presence of the slightest trace of sulphate in the potassium bromid. Such instances are, however, exceedingly rare and do not impair the position that mere traces of such impurities in these salts should not be excluded by the U. S. Pharmacopeia.

Another reason for not setting the standard too high is that it is impracticable to have two standards official, and since the pure food and drug laws in some states refer to the U. S. Pharmacopeia as the standard, druggists and dealers would be liable to prosecution for selling chemicals for commercial and technical purposes where so high purity is not required, which deviate from the official standard of purity. Such prosecution, mostly ill advised, has been frequent in Ohio, and has been carried on to such an extent in the United Kingdom as to make such laws exceedingly unpopular, and alienating the support of a large and otherwise law-abiding element.

In quite a different category is the degree of purity as related to freedom from poisonous compounds, frequently contaminating medicinal chemicals. Compounds of poisonous elements, such as arsenic, copper, lead, tin, derived from the crude products in the process of manufacture, can not be too rigidly excluded. That no convenience of manufacturers or additional cost, no matter how great, will have any influence on the standard of purity required by the U. S. Pharmacopeia in these particulars is a foregone conclusion.

ISOLATED PRINCIPLES.

The question of substitution of isolated principles for natural products has come to the front largely during the present decade. Many of the volatile oils are mixtures of certain principles, such as the oils of eucalyptus, caryophyllus, cinnamon, gaultheria, betula and sassafras. While the pharmacology on these articles is meager, it is assumed that the principal principles represent the therapeutic virtues of the respective oils, and it is contended that, since these vary considerable in the amount of these principles contained, greater accuracy and uniformity would be secured by the substitution of these principles for the natural oils.

Among the principles of this and similar classes likely to be admitted to the U. S. Pharmacopeia are: Anethol, eugenol, guaiacol and guaiacol carbonate and saffrol. Eucalyptol and methyl salicylate are now official.

SYNTHETICS.

The admission of synthetic products controlled by patent or proprietary rights has also received much attention. The ethical medical position is unequivocally opposed to the recognition of any substance whose composition is secret, or the manufacture of which is in any manner not free; and yet medical men, even the very highest authorities, prescribe them and exploit them in the journals. While the Pharmacopeia is supposed to have ignored them, such is not the case. The first synthetic medicinal chemical made by a patented process, salicylic acid, was admitted to the U. S. Pharmacopeia in 1880. In the present U. S. Pharmacopeia (1890) they are official of this class in addition to salol and lanolin, although under a name different from the trade name. On this point the instructions of the decennial convention of 1900 to the committee of revision were as follows:

> The committee of revision is authorized to admit into the Pharmacopeia any product of nature of known origin; also any synthetized product of definite composition which is in common use by the medical profession, the identity, purity or strength of which can be determined. No compound or mixture shall be introduced if the composition or mode of manufacture thereof be kept secret, or if it be controlled by unlimited proprietary rights.

The committee, desiring to adhere to the spirit, if not strictly to the letter, of the instructions of the convention, after considerable deliberation decided "to admit those substances for which there is, or may be, a product or process patent which expires during this decade (i. e., 1900-10), carrying with it the expiration of the trademarked name, as distinguished from a symbol or device."

According to this, none that are patented will be admitted if their trade-mark does not expire with their patent, and none that are trade-marked without being patented. Should legal advice conclude that trade-marked names expire with patent, then only such that are patented will be admitted whose patents expire before 1910. Among those proposed for admission under this decision are chloralamid, ethyl carbonate, hexamethylene-tetramin, iodol, methylene blue, phenacetin, piperazin, saccharin, phenyl salicylate (salol, now official), sulphonal, trional, aristol and salophen. The following would be excluded: Creosote carbonate, eucain, heroin, holocain, ichthyol, methyl acetanilid and orthoform.

ALKALOIDAL ASSAYS.

The U. S. Pharmacopeia of 1890 requires a certain alkaloidal standard for opium and cinchona, and the preparations of opium and nux vomica. This list will be largely extended, and assay processes fixing a standard of alkaloidal strength for the preparations of the following drugs have been proposed: Opium, cinchona and nux vomica, belladonna, hyoscyamus and stramonium, coca, guarana and kola, physostigma, ipecac, hydrastis, colchicum, pilocarpus, conium and jalap.

ANTITOXIN.

One of the most difficult questions for the committee to solve has been the admission of diphtheritic antitoxin. The principle of the Pharmacopeia heretofore has been that, inasmuch as the pharmacist is charged with the responsibility of maintaining the standard of identity, purity, quality and strength of all articles official, the Pharmacopeia must provide such definitions, descriptions, tests and assay processes as will enable him to determine whether or not the articles recognized by the Pharmacopeia respond to the official requirements. Since no biologic or pharmacologic tests have ever been admitted to any Pharmacopeia, presumably because these were not within the province of pharmaceutic practice, the admission of any article whose purity and potency could not be determined except through biologic methods appeared to be an insurmountable obstacle to the admission of any biologic product, and the convention, therefore, declared: "Physiologic tests for determining strength should not be introduced by the committee."

Owing, however, to the transcendant importance of the question of antitoxin, and inasmuch as the instructions of the convention were not directly mandatory, and especially in deference to the physicians on the committee who voiced the sentiment of the profession, evidently unanimous, as to the desirability, if not necessity, for the admission of antitoxin, and in order that the U. S. Pharmacopeia (1900) may not be charged with indifference to the greatest remedial agent of the decade it is to represent, the committee of revision decided to carefully consider the question. The matter was referred to a subcommittee, consisting of the physician-members of the committee, together with a number of eminent specialists in this field, with the late Dr. Walter Reed as chairman. Owing to the untimely and sad death of Dr. Reed, Dr. Theobald Smith was subsequently chosen to act as chairman, and this committee is now formulating a plan by which the antidiphtheritic serum will in all probability be admitted to the U. S. Pharmacopeia on the plan somewhat similar to that of the German Pharmacopeia of 1900.

POSOLOGY.

The question of dosage has always been a bugbear to pharmacists. Some (without being able to formulate the proposition, what is a dose? In the terse manner of Dr. S. Solis-Cohen, "A dose is enough") have felt that the Pharmacopeia was trenching on dangerous ground in endeavoring to adopt an authoritative list of doses. It was charged, however, that the lack of such dose list in the only legal authority on medicines materially lessened its value to the practitioners, and that such should be incorporated. The sentiment of the convention being almost unanimous on this question, the committee was instructed to state the average approximate adult dose, and, where deemed advisable, also for children, after all articles which are used or likely to be used internally. These are to be given in metric quantities, as well as in approximate customary weights and measures. It is to be the distinct understanding that these doses are not to be regarded as obligatory or as not to be exceeded by the physician whenever in his judgment desirable, and a declaration to that effect is to be prominently made in the book. Its purpose, then, is simply to serve as an authoritative reference guide to pharmacists and physicians.

NOMENCLATURE.

While the aim of the Pharmacopeia is to adhere to a scientific nomenclature, it can not invariably do so. To change old familiar titles of some chemicals so as to conform to the modern chemical nomenclature would create confusion, be inconvenient in prescribing and dispensing, and impair the usefulness of the alphabetical arrangement. Carbolic acid, for example, would appear as "phenol," and arsenous acid as "arsenic trioxid," if the chemical nomenclature be strictly observed. Since the scientific names are invariably appended as synonyms for such titles, as well as for such articles as may be admitted under trade names, there can be no objection to such deviation from the scientific nomenclature in the official titles as may be determined for the greater safety and convenience of physicians and pharmacists. Sometimes the title appears in contradiction to the chemical name, without apparent justification, as in "chloral" of the U. S. Pharmacopeia of 1890, which should have been "chloralis hydras"; chloral being a liquid, the hydrate of which is the well-known crystalline solid. The best of reasons, however, prompted this violation of chemical usage, namely, the belief that the use of the single word in prescribing would avoid the inevitable abbreviation of "chlor. hyd.," and thus prevent confusion with "chlorid hydrarg.," and consequent errors and complications.

DISCUSSION.

Dr. W. J. Robinson, New York—I consider the United States Pharmacopeia the best in the world. I am familiar with all of them, and as far as definiteness, succinctness and tests for purity are concerned it ranks above all. Still it is not popular with the physician. You will seldom find a physician who studies the pharmacopeia and rarely one who owns the book. It has always interested me to know why the physician never refers to the pharmacopeia. Among the many reasons I will mention one—it is the principal one—the pharmacopeia does not contain a very large number of substances which the physician prescribes daily. It contains about 200 various drugs like phytolacca, chelidonium, illicium, inula, mezereum, pareira, juglans, etc., and such substances which the progressive physician of to-day never prescribes, while many of those which are in daily use are

not to be found in it. We can not blame the pharmacopeia for not admitting these substances. Many of them are proprietary remedies with a perpetual copyright, but still it is wrong to exclude them altogether. The solution of the question would probably be to have a pharmacopeia of the same character as the present one which should contain all the standard drugs, but it should have a supplement in which might be given the chief characters of that large class of drugs which are frequently used and of which we know the exact chemical constitution. That would not be giving them the full sanction of the pharmacopeia, but at the same time it would be serviceable to the physician. Concerning the dosage, I think that would be a valuable addition to the pharmacopeia and render it more popular. Of course, there should be no ironclad rule about the dose, as the mention of a definite dose might lead to confusion, but if the average dosage were included it would render the book more useful to both physician and pharmacist.

DR. B. PIROSH, Chicago—The pharmacopeia should be in the office of every physician, for there is no better source from which to derive information in regard to the peculiarities of certain drugs. Concerning the bringing into the pharmacopeia of these preparations the patents of which have passed limitation, it should make no difference to the physician whether or not the patent letter has expired. I would prefer a remedy the patent of which is running to one the patent of which has expired—provided the composition and the physiologic action is known to me—for the reason that so long as it is protected and in the hands of only one manufacturer we know it is pure. When the patent is taken off and other parties take up the manufacture then there is adulteration. I think the doses should be incorporated in the pharmacopeia, as this would give the druggist and physician an equal opportunity to check each other in case of mistakes (on either part). I believe it would be well if the names of some of the drugs could be changed from time to time. Here in America, although it is our own fault, it seems to be a part of our business to tell the patient what he gets. The only benefit I can see from the knowledge of the patient about the drug he gets is to caution the next physician in case of idiosynerasy to a certain drug.

DR. W. B. HILL, Milwaukee, Wis.—The metric system and the dosage are two bugbears of the pharmacopeia of 1900. It is a simple thing to put down the figures, but to get the people to use them is quite a different matter. I believe the dosage is the key to the situation, but that means a real revision of the pharmacopeia, not a so-called revision. If we add a dosage system to the pharmacopeia, a system in which the strength of the preparations is given, within certain limits we make the use of the metric system possible; in other words, we should make it easier to name the dose in the metric system than in the English system. There would then be no question about its adoption. If we look over the various preparations we will find that tinctures vary all the way from 5 to 35 per cent., some for a very good reason, others without any reason. Under the metric system the tinctures could be classified in two or three classes, the stronger ones with a uniform dose of 1 c.c., the next class with average dose of 5 c.c., and the third class in larger quantities, such as the weaker tinctures. In this way we might so simplify the dosage that one could remember more easily in the metric system than in the English system. The greatest difficulty in training the memory so as to use the metric system is in the very small denominations. The trouble is in the unit, and it is difficult for the student to comprehend it. If the pharmacopeia were arranged in a double manner, on one side the tinctures and triturates, each with a uniform dose, and on the other side the fluid extracts and extracts with a uniform strength, I believe the metric system would be adopted within five years.

DR. O. T. OSBORNE, New Haven, Conn.—I believe the trouble lies in our hospitals. At the Yale Medical School I have taught the metric system for nearly twenty years, and will venture to say that not 25 per cent. of our graduates write prescriptions in the metric system to-day. We begin to teach materia medica in the second year, advanced pharmacology in the third year, and applied therapeutics in the fourth year. At the end of the second year the student is better versed in the metric system than he is at the end of the third year, and at the end of the third year he writes better prescriptions than he does at the end of the fourth year. This is because he is constantly coming in contact in journals, textbooks and clinics with prescriptions written in the old system. When the student gets into the hospital he sees no more of the metric system, and when he leaves he has almost forgotten that there is such a system. Hence I believe that until the hospitals abolish the old system and take up the new, the medical colleges can not advance the use of the decimal system. As to teaching the doses of preparations, as an example, I classify the tinctures into poisonous and non-poisonous and put as many as possible together under one dose. In this way the student soon learns that a poisonous tincture has a dose of a few drops, and a non-poisonous a dose of a teaspoonful.

DR. H. A. MOODY, Mobile, Ala.—Dr. Osborne has voiced my experience. I have been teaching materia medica for about ten years. In the first year my students are required to copy prescriptions from the blackboard in the metric system and it is discussed—and I mean discussed—the students are invited to participate in the discussion and compare the metric system with the old system. In the study of therapeutics the students write the prescription in the old method first and then translate it into the metric system in order to be masters of both systems, for this is necessary if they are to practice in rural districts. The result is that they gravitate to the old system, and nothing seems to stop them. I believe it was Lincoln who said that "you can not fool all of the people all of the time." So I think there must be some solid foundation for the preference for the old system or it would have been dropped long ago. It is a fact that it is the most popular system all over the United States to-day. Dr. Robinson said the pharmacopeia contained a lot of drugs that had become obsolete and were never used by progressive physicians, and among other substances he mentioned phytolacca. Now, phytolacca is not obsolete all over the country by any means. This illustrates how utterly impossible it will be to satisfy all parties by any decision as to which drugs shall be placed in the pharmacopeia and which shall be omitted, or go into the appendix. You will be sure to offend the sense of propriety of some. Another statement referred to was the physiologic test of drugs. The committee decided that they could not use that test of drugs for the pharmacopeia. It seemed to me that this referred principally to the animal serums. Now, there are other drugs whose strength we can ascertain in no other way, such as ergot, digitalis, etc. Is the physiologic test used to standardize medicines such as these?

DR. F. R. WEBER, Milwaukee, Wis.—We have in our school those who prefer the old system and those who prefer the metric. The effect of this is to accustom the students to one as much as to the other, and it is easy for them to prescribe in either system. It is only laziness that causes them to ignore the metric system. When the metric system was introduced in Germany, within a year all the old books and the old systems were changed. If our books would change and only contain the metric system how quickly would the nation throw off the old system and take up the new. The trouble with the United States is that we still prefer to read English articles, and in England it is practically impossible to introduce the metric system.

DR. C. S. CHAMBERLIN, Cincinnati—There must be some reason for the hold which the old system has on us. I studied both systems when at college and for three years taught chemistry, using the metric system entirely. In my practice I tried to use the metric system, but I never got beyond the point where I did not have to translate from the old into the new. In regard to phytolacca, Dr. J. B. Shoemaker has an article in the October, 1901, *Medical Bulletin* which covers

at least four pages, in which he declares that it is one of the best alteratives and the best of all remedies in mastitis.

PROF. C. S. N. HALLBERG—With reference to the scope of the pharmacopeia it has been very difficult to get anything like statistics in the United States. We have compiled the different kinds of articles which enter into hundreds of thousands of prescriptions in the different sections of the United States and we never before realized what a vast country this is. The medicines which may be considered obsolete in one section are used in great quantity in another section. You must remember that we have here in the United States a medical and a pharmaceutical population which is cosmopolitan. The United States Pharmacopeia may well be considered a combination of all the pharmacopeias of Europe revised and condensed. The committee does its best in getting information as to what these articles are and which should be admitted. As to the supplement, which should include a number of articles, as suggested by Dr. Robinson, I believe that is a questionable expedient. The pharmacopeia has a legal standing, not by act of congress, but by laws in the states whereever there is legislation affecting pharmacy or pure food and drug laws; in such states it is recognized as the standard. Of course, if these articles were simply enumerated therein it might serve a purpose, but that is doubtful. The American Pharmaceutical Association issues a National Formulary and it might be advisable to enumerate in that such articles as Dr. Robinson suggests. That the strength of galenic preparations should be based on the posology instead of on the drug strength is a new proposition and one not recognized in any pharmacopeia. The pharmacopeia is first of all the hand-book of the pharmacist; it is his manual from which he makes his preparations, as far as the galenic preparations are concerned, and because of the use of the metric system it is desired to maintain the percentage proportions. Any change, therefore, which would involve too much deviation would be embarrassing to the pharmacist. To fix even the general average doses of these preparations would make them of a strength without any determined relation to the drug. Dr. Wood, for instance, administers tincture of digitalis in teaspoonful doses, while others give one-fourth that amount. Now, what should be the drug-strength of tincture of digitalis? To obviate this confusion last year at Brussels there was a conference "for the unification of the strength of potent remedies." Dr. H. C. Wood, Philadelphia, attended this international conference, at which were representatives from every country in Europe. It was decided that tinctures should be in two classes, the potent drugs of a 10 per cent. and those less potent of 20 per cent. strength. That will be a great pharmaceutic convenience, though it does not conform to Dr. Hill's suggestion except to the extent that there is a distinction between potent drugs and those that are less potent. But here arises a great difficulty; the tinctures of the most potent drugs are of the greatest drug strength; tincture of aconite is 35 per cent., tincture of veratrum viride is 40 per cent. in strength, while tinctures of drugs which can not approach these in potency are only 10, or 5 per cent. The committee has, however, decided to follow this principle, and is going to change the strengths of the tinctures of aconite and veratrum viride to 10 per cent. There is a tendency toward the unification of potent remedies, and this conference fixed the strength of all arsenical solutions at 1 per cent., which is uniform in all the pharmacopeias. The question of patents raised by Dr. Pirosh is scarcely within the limits of the paper. A patent is limited to seventeen years. There is no objection to a patent, but what we call "patent remedies" are of secret composition and some get the name of being patented from the fact that the name or label has been copyrighted and the profession is not furnished the formula. The only way to learn the metric system is to work with it. Pharmacy students have to work with the metric system in all branches. Annually, during the course, a vote is taken among the students as to their preference, and only once in ten years one man said he preferred the old system after working with the metric system for three months. The great advantage of the metric system is shown in recent works on pharmacy and therapeutics. In the older works an ointment, for example, has to be prescribed "a dram to the ounce," or "30 grs. to the ounce." Compare that method of expression to the clear, concise statement that an ointment is 1 per cent., or 2 per cent., or 10 per cent. strength. Applied to solutions and preparations for external use the metric system goes hand in hand with percentage strengths, and is the only scientific method of expression.

HOW FAR SHOULD THE SPECIALIST IN RHINOLOGY AND OTOLOGY PRESUME TO TREAT THE SYSTEMIC CONDITION OF HIS PATIENTS?*

CAROLUS M. COBB, M.D.
BOSTON.

In many of the papers dealing with the treatment of catarrhal conditions of the nose, throat and ears, we find such suggestions as the following: "The general health should be carefully looked after," "any deviation from the standard of health should be corrected," some putting the case stronger and claiming that no success can be hoped for unless the general health of the patient is made perfect, or at least made better. If this is the case, our first inquiry should be in regard to the qualification of the specialist. Is he able and prepared to make a diagnosis of all the obscure conditions of the general system which the general practitioner has overlooked? If he is able to do so will he do it in the short time which he generally devotes to the consideration of a case? Assuming that he is able and willing to do this, should he treat the case or should he refer the patient to his family physician, explaining to him that the local disease depends on such and such a general condition? These are serious questions, and it is fully time that we stated definitely just what we mean. In discussing these questions I shall simply state my views with the purpose of arriving at some definite conclusion as to the course to pursue.

It is a well-known fact in all branches of human knowledge that the more distinctly a man is a specialist, the less his opinion is worth about general questions, and often about subjects intimately connected with his own specialty. If this is so in the exact sciences, how much more is it likely to be true in medicine? There are several reasons why, in my opinion, the specialist is not as well qualified to make a diagnosis and, therefore, to treat the general condition. The first of these is the fact that he sees most diseases through the medium of his own specialty; secondly, he often does not have the requisite training, and if he has it he soon gets out of touch with the subject of general medicine; thirdly, he does not keep touch with the literature of general medicine; fourthly, he does not have at his command the necessary instruments of precision; fifthly, the patient comes to him for another purpose and does not volunteer information with which his family physician is perfectly familiar, and, lastly, he does not take the necessary time to investigate the functions of the different organs and to obtain a complete history of the general health. It is only by such a painstaking investigation that an accurate diagnosis can be made.

On the other hand, the specialist often sees the local manifestations of disease conditions which may have been overlooked and which perhaps the family physi-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

cian has had no opportunity to investigate. It has been my experience that the general practitioner is usually grateful for the light which our examination may throw on a case. The very ease with which we are able to make a diagnosis of some general diseases by their local manifestations leads us into the error of thinking that we are able to diagnose with equal ease all the diseases of the body. In reality, the diseases which we are able to diagnose from local manifestations are very few, and they are often far advanced before the local characteristics are sufficiently marked to enable us to arrive at definite conclusions. We form impressions of cases, but we should bear in mind that clinical impressions are not always clinical facts. To make a diagnosis of systemic disease requires time and patience, a thorough knowledge of clinical medicine, the necessary instruments of precision, and constant practice with the privileges of a large clinic. Are we prepared for this work? The papers in which the systemic factor is most strongly insisted on do not present internal evidence that this course has been pursued, but, on the other hand, the papers abound in vague illusions and loose generalities until we find ourselves in the position of the lady who had been discussing the subject of the future state with Dr. Johnson: "She seemed desirous of knowing more," says Boswell, "but he left the question in obscurity."

A statement that the general health should be attended to without any suggestions as to what conditions may, or do, unfavorably affect the so-called catarrhal disease of the nose, throat or ears, is not of much use as a practical guide. Do we mean to say that the local lesions are caused by the general condition, or do we mean that they are only made worse by it. If the systemic condition is an important etiologic factor in the production or continuance of the catarrhal diseases of the upper air tract, then it is high time that we should have some definite knowledge of the subject. We should know what diseases act as causes and in what way they so act.

So far as one is able to judge from the writings of the men who make the claim of systemic influence, they attach a great deal of importance to the form of intestinal absorption that goes by the modern name of uric acid poisoning. I do not deny the existence of the condition, but this is hardly the place to enter into a discussion of whether uric acid has anything to do with it. Those who are firmly convinced that it does would do well to read the paper by the President of this Association on the subject. Whatever the etiology of the condition, the question for us to decide is how much of a factor is it in the production of local disease in the nose, throat and ears. There is no doubt that every secreting surface in the body participates in the effort to eliminate these poisons, and the nose and throat, having secreting surfaces, share in this effort. This is manifest by increased secretion and local irritation, which should, and probably does, continue while the process of elimination is going on, but should not continue after elimination is completed. It may be urged that many of these patients are in a state of chronic poisoning, but this is not usually the case because it leads to such a degree of ill health that some effort is made to correct the condition. If no effort is made by the patient, Nature usually takes a hand and helps to correct it. After granting all that may be caused by intestinal absorption, it must be admitted that the term uric acid poisoning has answered as an explanation of a good many things which we did not understand. It is a notable fact that as we know more of any subject we are less likely to seek for an explanation of any obscure condition from this source. It is safe to claim that uric acid does not offer an explanation of chronic catarrh of the nose, throat and ears, and that we must seek for other etiologic factors. The question is what other diseases do have an influence. The diseases which we shall discuss are perhaps not all that may serve as etiologic factors, but will give an indication of what we have to deal with and of some things that had better be let alone so far as we are concerned.

Syphilis and tuberculosis we have always with us, and when the lesions are located in the upper air tract they may very properly be treated by the specialist. Nephritis and diabetes, as well as leukemia, may have local manifestations in the nose, throat and ears, but the only relief which these patients obtain is from the treatment of the general condition.

The sequelæ of the diseases of childhood, the eruptive fevers, influenza and pneumonia, may include not only suppurative diseases of the ears, but also catarrhal disease of the upper air tract. If we were able to trace most of the cases of catarrhal disease of the upper air tract to their source, I believe that we should find that most of them originated in the diseases of childhood or in the infectious diseases. It is believed by many otologists that most of the cases of ear disease originate in childhood, and that if a person escapes ear disease until he is 20 years of age that he will, barring accidents, escape during life. I believe that the same statement holds true in regard to the catarrhal diseases of the nose and throat. Included in the list of accidents are the inflammations which may occur during the course of the infectious diseases. It is worthy of note that persons with perfectly healthy upper air tracts are not so liable to these accidents as are those who already have disease there. These sequelæ furnish by far the largest class of cases with which we have to deal.

It has been claimed that anemia and malnutrition from whatever cause are potent factors, but how far this is so is a mooted question. It is, however, extremely doubtful if they ever act as a primary cause. Disease of the upper air tract is often a potent cause of malnutrition, but it should not be forgotten that malnutrition and catarrhal disease may be associated in the same patient without either having a direct bearing on the other. It is often a very complex question which we have to decide, still it is always well to bear in mind that catarrhal disease may be, and often is, a source of ill health.

It has been claimed that there is no special pathology for aural disease, and the same may be said in regard to the diseases of the nose and throat, but, notwithstanding, we have in the chronic diseases of the nose, throat and ears a condition which, with one exception, we do not find in other parts of the body. This peculiarity is not due to a different etiology or pathology, but rather to the anatomic construction and the functions of the regions under consideration. The acute inflammations are due here, as in other parts of the body, to bacterial infection, and the chronic conditions are the sequelæ of the acute attacks. The exception noted above is a disease of the ribs following pleural empyema, which closely resembles that most hopeless of all ear diseases, spongifying degeneration of the labyrinth. The disease of the ribs is undoubtedly the sequel of the pleural inflammation, and, for anything that we

know to the contrary, the disease of the temporal bone may be the sequel of an acute inflammation. In fact, we know hardly anything about the disease as yet, except that we are able to recognize it and have studied the condition of the bone after death. So far, any treatment which has been employed has been absolutely without effect, and this does not argue an extensive knowledge of the disease.

Progressive deafness is rarely influenced by rheumatism, and almost never associated with deforming arthritis. Patients with progressive deafness are not more liable to have deforming arthritis, and patients who suffer from deforming arthritis rarely ever have trouble with their ears. It would seem that the two diseases should be more often associated if there were any connection between them.

We have to deal with a disease which is persistent and often progressive, and one that does not depend on the systemic condition only in a general way, at least we are not able to claim that it depends on any definite systemic condition. To what, then, can we ascribe the chronicity of these cases? The explanation of this is found chiefly in the anatomic construction of the parts. We have here a large number of cavities which, when once they are infected, are not easily healed. Spontaneous recovery is slow because the drainage is not good even when there are no deviations from the normal anatomic construction, but we often have to deal with more than the usual amount of obstruction either by reason of faulty construction of the parts or as a result of disease. If we add to these causes focal disease within the cavities and the difficulty and often impossibility of direct treatment of the cavities we shall find a sufficient explanation of why these cases run a protracted course.

From all this I do not wish to be understood, for a moment, as claiming that it is not necessary for the specialist to have a thorough knowledge of general medicine. The more medicine the specialist knows the safer patients will be in his hands, and it is not only necessary to be a thorough student of medicine, but it is also necessary to have practiced general medicine. The practice of general medicine broadens one medically and intellectually, and while it is true that when he enters special work he soon loses that delicate touch with general medicine which enables him to form a true estimate of the general health, still he never grows so narrow medically or mentally as he would have done if he had never had the practical training in general medicine. Those who have become good physicians before they become specialists are not usually the ones who attempt to treat the general condition, because they realize how difficult it is for one who is out of touch with general medicine to make a diagnosis of the systemic condition. We have, then, so far as we are concerned, a local condition with which to deal, and we shall be doing a service to our patients when we refer them to their family physicians for treatment of any condition of ill health which may exist. If, however, the local disease is caused by the systemic condition, I can not help feeling that the patients are in a serious situation, because the specialists, as I have attempted to show, are out of touch with general medicine, and are, therefore, unable to treat successfully the general health, and the general practitioner, either from lack of training or because he is too busy, can not carry out the local treatment which experience has shown is beneficial in these cases. The ideal specialist would be the general practitioner who has had a thorough training in that particular branch of special work, but it is hardly possible, under present conditions, for such a one to receive the support of the profession. If we keep constantly before us the fact that all special work is only an adjunct to the work of the family physician and labor intelligently with him for the single object of relieving our patients, we shall have the satisfaction at least of knowing that we have done all that it is possible for us to do for them.

DISCUSSION.

DR. SARGENT F. SNOW, Syracuse—The relation between systemic disorders and local affections of the head is one of the points that determines the success of the treatment of chronic catarrhal affections. A specialist who treats chronic catarrhal affections of any organ and does not recognize the influence of systemic conditions, is in a bad way, and so are the patients that may come under his care. I thoroughly agree with Dr. Cobb that there are many things to prevent the specialist from doing for these patients as he would like, but he must not be too technical and draw his lines too fine. It has been my experience that no case of advanced deafness or advanced catarrhal states depends on local conditions alone. A bad case of catarrhal disease of the ears or throat is probably associated with some systemic disorder or some great fault in personal habits. Bad liver and intestinal disorders will produce congestions of the head membranes just as surely as will bad habits and exposure of the body or keeping the skin tender by hot baths, etc. Local morbid nasal states must be taken care of, but on that alone we must not rely if we expect to help our chronic cases.

DR. GEORGE E. SHAMBAUGH, Chicago—I agree heartily with the essayist. I believe medicine has to-day arrived at a point where no man can understand all about medicine. Internal medicine itself is just as much a specialty as is the study of the nose, throat and ear. We usually discredit a man who presumes to treat all the specialties as one who goes beyond his bounds and can not do anything thoroughly. So the specialist who attempts to treat general diseases makes a mistake. I believe it is best to be in very close relation with the family physician in these cases. The better class of general practitioners recognize specialism and heartily co-operate with us in our work.

DR. D. A. KUYK, Richmond, Va.—In the future we will have fewer ready-made specialists than we have had in the past; they have been chiefly the result of faulty instruction in the colleges. As our knowledge increases our courses increase and become more intensive. I impress on my students the importance of thorough medical knowledge. A man should not undertake to practice a specialty until he has had from five to ten years of general medical practice. Then, when he finds his adaptability to a specialty, he may go into it. The specialist of the future will be a better prepared man. I look on these local conditions largely as manifestations of general conditions. No medicine can possibly approximate the result we get in many cases from exercise. If we keep our oxygenation, combustion and elimination in good condition, we will often be able to defy the micro-organisms.

DR. W. SCHEPPEGRELL, New Orleans—The trouble is not so much that the general practitioner attempts to practice this specialty as it is that he ignores it. As an illustration, a child had been treated eighteen months for malarial fever, of a recurrent type and had been given quinin in large quantities and had been sent to places where malaria did not prevail, all to no avail. She had a discharge from the nose, and when the patient came to my office I removed a rhinolith which had caused considerable irritation of the tissue of the nostril, and the discharge of pus and from its absorption, the fever. The child was well in a few days. On one occasion I was about to perform a tonsillotomy. The child was very nervous and had some symptoms of fever. I asked if the child had been ill, but was told that it was only nervous. The nurse found the temperature 101.5 F. I declined to operate. I did not see the

mother until three weeks later. She then told me that the day following the visit to my office, the child's face enlarged with mumps. If I had operated the swelling would have been ascribed to the operation and not to the mumps.

DR. CHARLES H. BAKER, Bay City, Mich.—Undergraduates have not had proper training in the specialties. The general practitioner is not sufficiently alive to those conditions, which —if he recognized them even though he did not treat them— would redound to his credit and would strengthen him. Frequently men have sent cases to me without a diagnosis or with a diagnosis as likely to be wrong as right. But the general practitioner makes himself stronger in the esteem of his clients when he recognizes these cases and sends them to the specialist. The men who are the most successful practitioners are also the men who are in the closest touch with the specialists. Sometimes cases are sent by men who are absolutely incapable of giving the necessary general treatment, and then it becomes a very serious question whether we should overstep the bounds of our specialty that treat the general conditions when necessary. In such cases, if I had sufficient influence with the general practitioner, I give him suggestions along from time to time but do not hesitate to give the patient necessary treatment to secure results.

DR. O. JOACHIM, New Orleans—Just as we need the knowledge of general surgery, we need also a knowledge of general medicine in order to treat the general conditions of these cases. I have found, as has Dr. Cobb, the greatest willingness on the part of the physicians to second our efforts, and they are glad to have us make suggestions and give them points, and sometimes to the betterment of the patient they can show us points. I have known patients to leave the specialist, and under general treatment by the general practitioner receive benefit which the specialist was not able to give. The laity and the physician often speak of "catarrhal" diseases, which is a very unmeaning term. We have more precise terms than "catarrhal diseases," and we should eliminate this term as far as possible from our discussions, except when referring to the diseases to which a catarrhal process strictly relates.

DR. H. W. LOEB, St. Louis—Of course, the more knowledge a man has before he becomes a specialist the better he will be. A few years ago I looked into the general treatment of chronic pharyngitis and found some thirty different plants. The majority referred to the treatment of the stomach. Then I looked up the treatment of the stomach diseases and found a great number of conditions which I did not understand, and concluded that I for one could not treat the general condition in these cases intelligently. I am sure Dr. Cobb feels as I do, that there should be considerable limitation in the treatment of the general condition. The point especially to be brought out is, not that the general practitioner does not send to us the cases often enough but rather that we do not send our cases to the general practitioner often enough. In that way we often fall into error.

DR. CHARLES W. CRUMB, Utica, N. Y.—This question is of great importance to me, because with a large country district surrounding, I have many cases sent by the general practitioner. In some cases I have a great deal of trouble with the general practitioner. For instance,, take a case in which I am sure there is a specific element, if I say to the general practitioner that it is a specific case, he will often say that he knows from the history that it is not. Often we can not impress on them that certain cases are specific. What shall we do? Shall we let the patients go back and have recurrences or shall we treat them?

DR. GEORGE L. RICHARDS, Fall River, Mass.—I think it is entirely a question of tact and common sense. When the patient comes to me for treatment he is entitled to the best I can give him, and if that requires a correlation with the general practitioner he ought to have it. But many cases come to the specialist of their own accord. Sometimes other things than spraying are required, and if a prescription is necessary I think he ought to have it. The patient has some rights and he should not be required to go back to the general practitioner for a prescription and pay two fees. The general practitioner is in the best of relations with me and we work together. But if I find a general condition accounting for the nose or throat condition, I frequently prescribe for it. But, of course, I would not treat general conditions, such as mumps, etc. Nor do I send every case to the general practitioner for a dose of calomel when that is required. When you have a case sent to you for diagnosis and initial treatment you are compelled to return the case to the general practitioner, by the requirements of ethical conduct. A little tact and common sense will take care of this whole subject, and it seems to me we are largely threshing a man of straw here.

DR. C. M. COBB, Boston—The statement of Dr. Richards does not seem to cover the ground. We are often told that the catarrhal diseases, at least in certain cases, depend on a constitutional disease or condition. We want to know just what it does depend on, what the constitutional disease or condition is. Unfortunately there is too often a feeling of distrust on the part of general practitioners toward the specialists. They consider them to a certain extent rivals in business. The patients do come to the specialists often of their own accord and the specialist will give them general treatment, for instance, a dose of pepsin or something for indigestion and they will be all right. Now, are we justified from the simple statement of the patient to go ahead and prescribe for him? I do not think we are. Not long ago a man came into my office with some trouble with his nose and throat and I found he had too much other trouble, and I asked his family physician's name and sent him to his physician. Another patient came to me and I treated him once and he recovered. He came back again because of pain, but I could find nothing in the way of a local disease, and I sent him to his family physician with a note saying that something was poisoning the patient, but I did not know what it was. The physician later told me that it was a case of malaria. I do not suppose that would occur here, but it did occur in Massachusetts. The trouble with the specialists, as well as with the general practitioners, is that they often attempt to do things they can not do. In one case I was firmly convinced that the patient had hay fever. She came once or twice. Later I saw the family physician and he said she had had convulsions, and an examination of the urine showed chronic nephritis, from which she died. If she had complained to me of anemia or some condition of the stomach I might have given her something that possibly would do no harm or that possibly might have done harm. If the general practitioner will say it is a simple case, all well and good, but if we are to say a case is simple or serious it is a very different thing. The patients often say that they have such and such a physician for simple things, but if there is anything serious they have somebody else. I do not know how they determine whether it is a simple or a serious disease. Ninety per cent. of our cases are of local origin, if we take out of consideration syphilis, tuberculosis and the malignant diseases. Often it is better for us to look the cases over, for sometimes the general practitioner may make mistakes. But he is not so likely to make mistakes about the general conditions as we are. Of course, we all at times make mistakes. Sometimes the patients come to me and say they have no confidence in their general practitioner. I think the specialist will do better if he will stick to the patient's family physician, for it is not our business to pick out their family physician. We should remember that catarrhal disease means no particular disease. After the local disease is treated, usually the diathesis or catarrhal disease disappears.

A Case of Nutmeg Poisoning.—According to *The Lancet*, a young woman took, to restore the menses, a whole nutmeg grated in a wineglass of gin. The monthly flow had been delayed two weeks, and the patient feared pregnancy. Convulsions ensued and the patient was found in collapse by the medical attendant. General condition began to improve in about an hour after treatment was begun; her stomach was thoroughly emptied. She remained in muttering delirium for one night, slept heavily the next day and awoke fully recovered.

THE EARLY MANIFESTATIONS OF LARYNGEAL TUBERCULOSIS;

THEIR FREQUENCY AND TREATMENT.*

H. H. BRIGGS, A.M., M.D.
ASHEVILLE, N. C.

The early rather than the late manifestations of laryngeal tuberculosis are chosen for consideration because the lesions of the advanced stages are self-evident, and our services to such unfortunates are but meager and palliative, while the earlier lesions are more difficult of recognition, but may be, by perseverance, occasionally checked and possibly eradicated.

It is not the scope of this paper to discuss the etiology of laryngeal tuberculosis, nor whether it is occasionally primary or invariably sequential to pulmonary tuberculosis, nor whether, as a sequela, the invasion is endogenetic or exogenetic, but rather to consider the pathologic changes prior to the ulceration.

It has been my custom to examine the larynges of subjects of pulmonary tuberculosis with a view to ascertaining the condition of the larynx prior to the characteristic tumefactions and infiltrations. The great majority of these subjects have a subacute or chronic laryngitis which does not differ in laryngoscopic appearance from a laryngitis of diathetic or climatic cause. There is either uniform thickening of the mucosa or an irregular thickening and hyperplasia of reddish hue of the ventricular bands and arytenoid commissure, presenting dilated blood vessels and covered with thick, grayish mucus. This laryngitis persists notwithstanding the ordinary treatment for such conditions and is principally dependent on the tubercular dyscrasia. The fact that such larynges are often constantly irritated by pus may be a most potent factor causing its persistence.

Notwithstanding the opinion of Bosworth to the contrary, there seems to be ample proof that the laryngitis in pulmonary tuberculosis is predisposing to the laryngeal tubercular invasion, although the laryngitis itself is probably due to the tubercular dyscrasia and the concomitant cough. Solis-Cohen says that "a predisposition to catarrhal inflammations of the mucous membrane may be regarded as the chief cause of laryngeal tuberculosis," that "many of the chronic cases begin with subacute catarrh which can not be distinguished as peculiarly precursory to laryngeal tuberculosis either by subjective symptoms or by laryngoscopic inspection," and that "in the primitive cases a severe exfoliative laryngitis is the direct predisposing cause" and affords entrance to the tubercle bacillus.

This chronic laryngitis, neither pathognomonic nor characteristic of tuberculous laryngitis, is, nevertheless, the initiative step in the great majority of cases to that lesion, and should be considered as possibly leading to a serious complication in any pulmonary case. We would concede the fact that there may often be a laryngitis in a tubercular patient from other diathetic cause, bearing no sequential or etiologic relationship to the tuberculosis, and also that even many such ulcerative larynges are non-tubercular.

In keeping with the foregoing it has been my observation that three-fourths of the pulmonary patients have some nasal stenosis, and seemingly at variance with the opinion of Fletcher Ingals that the nasal catarrh protects rather than predisposes to pulmonary tuberculosis is the fact that the majority of the laryngeal cases have septal or turbinate deformities.

The acute form of laryngeal tuberculosis usually begins when softening has taken place in the lung and when the laryngitis has reached its crisis. Anemia of the parts is not present and the first sign is a hyperemia which may last days or weeks, following which are the multiple erosions on the laryngeal surface of the epiglottis and arytenoids with, or soon to be followed by, tumefaction in the epiglottis or aryepiglottic folds. These erosions may simulate very closely aphthous ulcerations and are distinguished principally by their multiple character. They eventually enlarge, grow deeper and coalesce, and may precede or occur on a tumefaction, or the latter may develop and remain without an erosion or ulceration.

The chronic form usually begins with an anemia in the arytenoid commissure, arytenoid bodies, ventricular bands or epiglottis, and presents a homogeneous and smooth yellowish-gray color of the intumescent membrane. There may be the so-called mottled appearance caused by spots of deeper hue. This pallor may be a part of a general anemia, and is sometimes present throughout the respiratory tract unassociated with any laryngeal lesion. In either form the parts become thickened early, presenting an infiltrated interarytenoid space, a club-shaped arytenoid or a turban-shaped epiglottis, and later there is sometimes thickening of the parts adjacent to these, especially if there are subacute attacks of laryngitis. An infiltrated ventricular band may obscure a portion of a thickened and congested cord or the latter may be involved in the general pallid edematous condition and yet show in contrast congested blood vessels. The bands may show a nibbled appearance of their edges, and the same may be true of the cords, especially on and near the processus vocalis, where the condition is difficult to detect.

The local subjective symptoms of the early stages may be wanting or simply those of a chronic laryngitis. There is usually a hacking cough, pricking, itching and dryness of the throat, hoarseness and later aphonia and occasionally dysphagia. The cough is distinctly laryngeal unless the repeated hackings induce a spasmodic and expulsive deep cough, but the effort is primarily to free the larynx from the tickling and dry sensation.

The impairment of the voice depends on the nature, location and extent of the lesion. In the chronic cases there may be constant hoarseness which may tend to clear up after a meal, or the drinking of liquids, and yet a large per cent. shows no hoarseness in this stage. If the lesion is in the interarytenoid space there sometimes occurs a diphonic voice.

The pitch limits are also affected, but usually the upper suffers more than the lower. The volume may be markedly affected, the immobility of the parts necessitating a forced expiratory act to start the cords vibrating, and even then weak phonation results. One or more words of a sentence may be whispered.

Odynphagia is seldom present in the pre-ulcerative stage, but may occur when the epiglottis, aryepiglottic folds, or the posterior portions of the larynx are involved.

The diagnosis of secondary laryngeal tuberculosis depends on the tubercular history, symptoms and signs. A persistent, chronic laryngitis with the supervention of hoarseness or a weakening of the voice is always suspicious. In the primary cases the attack usually dates

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. George L. Richards, O. Joachim and G. V. Woollen.

back to a severe cold, and the hoarseness is more marked than in the secondary cases. In any case, while the symptoms are of value, the diagnosis will mainly depend on the laryngoscopic appearance. Von Ziemssen doubts the possibility of recognizing the lesions laryngoscopically, yet Lennox Browne considers the laryngeal picture as characteristic. A tubercular lesion presents an infiltration of the mucosa proper, an exsanguination and a diminished secretion. The color is a shining grayish or yellowish pink and the location is usually in the interarytenoid space, arytenoid bodies, ventricular bands, epiglottis and vocal cords. The interarytenoid space at first shows only a thickening, but later a roughened convexity anteriorly. The arytenoid bodies and aryepiglottic folds become club-shaped to the extent of obliterating the Wrisberg and Santorini prominences. The infiltrated ventricular bands may obscure the ventricles and often cover the cords, and the latter, especially the processus vocalis, quickly become congested and nibbed by erosions. The turban appearance of the epiglottis seldom appears in the early stage, but usually follows after other parts have broken down.

The evening pyrexia, anorexia, small and rapid pulse and cough assist in diagnosis.

The presence of the tubercle bacillus can not be regarded as of diagnostic value except as being indicative of a lesion somewhere along the respiratory tract.

The course of the disease depends much on the general condition, the extent and course of the pulmonary lesion, if such exists, the nature and location of the laryngeal lesions, the co-existence of syphilis, and on the treatment. The acute and miliary forms are rapidly fatal. The prognosis in the chronic cases is also, of course, unfavorable. As a rule, the laryngeal condition keeps full pace with that of the lung. In a few cases under favorable conditions and where the physical resistance is good the infiltrations or even the tuberculomata may remain indefinitely or disappear, especially under persistent appropriate treatment and climatic influence.

Of the greatest importance is prophylaxis, especially in those suffering from pulmonary tuberculosis. Aside from the general treatment indicated for the tubercular dyscrasia, there should be, at intervals not exceeding one month, a careful laryngoscopic examination made and, at the first indication of a laryngitis, appropriate treatment should be begun. By this is not meant a routine spraying, but each patient having anything but a normal larynx should have whatever treatment may be necessary for the condition present. Fewer laryngeal complications to pulmonary tuberculosis would ensue if this were done.

Overuse of the voice, faulty phonation and needless hacking and scraping the throat, much of which is a habit rather than a necessity, invite the inflammation.

Nourishment is of prime importance, and to this end forced feeding within physiologic limits, with moderate open air exercise and abundance of sunshine is necessitated. The greater part of the twenty-four hours should be spent out of doors. Regulated long hours of sleep in a cold, southern-exposed room with open windows, barring direct drafts, are essential.

The effect of climate is disappointing as directly influencing the local lesion, but indirectly, acting on the general predisposition, is second in importance to nourishment. The greatest number are benefited by a climate of moderate temperature and of medium hygroscopic conditions, in an elevation from 2,000 to 3,000 feet. Air free from dust and gases of the cities, purified by moderate winds and rainfall and an abundance of sunshine has proven beneficial to many having laryngeal complications in whom the process is either arrested or cured. The warm, moist climate of lower elevation is better suited to a few who are not enervated thereby.

The voice should be completely suspended in the acute form or during an acute exacerbation of a chronic case. To facilitate this, which is difficult to accomplish, a pencil and pad should be used by the patient and his necessary communications written thereon, and during the greater part of the day he should be left alone, thus eliminating the temptation of speaking. In the less severe cases moderation of the voice and in the amount of speaking should be insisted on. In no case should singing or reading aloud be permitted. Many patients have a faulty mode of speech specially fatiguing to the larynx. The effort is laryngeal rather than from the chest, and often an affected voice from habit must be contended with.

There is too much routine spraying and inhaling treatment in vogue, throwing into the larynx variously combined oils and liquids, many of which are not only non-solvent but actually coagulating to the secretions and instead of cleansing and soothing often form a tenacious, irritating mucous coat nauseating to the patient. The principles of treatment are not unlike those in other lines of surgery, cleanliness being the prime factor. If the parts are covered by tenacious mucus or debris a bland solvent such as a solution of sodium bicarbonate, sodium chlorid, sodium biborate or sodium sulphate should be gargled, sprayed or applied on a cotton sponge thoroughly but quickly with the least possible irritation to the parts. The patient should not be requested to assist in dislodging retained secretion by repeated coughing or hawking for the effort is too fatiguing for an organ needing rest and induces hyperemia. After the cleansing process, the inflammatory condition should receive such treatment as is indicated, and usually astringents, solutions of zinc chlorid, tannate of glycerin, creosote and iodin, pyoctannin and silver nitrate on a cotton swab are most efficient.

Any pathologic condition of the nose and pharynx should receive appropriate treatment. Not only that the pulmonary patient may be able to supply his lungs plentifully with air, but that the larynx may be the recipient of air properly warmed, filtered and moistened, every nasal and pharyngeal stenosis should be reduced, and to this end no moderate degree of cachexia will contraindicate the removal of septal spurs, or deflections, hypertrophied turbinates and adenoids, for the increased oxygenation will more than compensate for any debilitation resulting therefrom. Such measures are to an extent prophylactic to tubercular laryngitis.

There is much diversity of opinion as to the indications for local treatment of the pre-ulcerative conditions. Theoretically, stimulants to the anemic and sedatives and astringents to the hyperemic areas are indicated, and my clinical experience conforms to this. Where there is a general anemic condition of the larynx and a beginning tumefaction, a stimulating spray of 20 per cent. menthol in liquid vaselin, or 50 per cent. guaiacol in olive oil will tend to restore the capillary circulation. Propelling sprays with hot instead of cold air adds to their efficiency.

As the tumefaction advances an application of iodin, creosote and potassium iodid in glycerin and water often has an absorptive action. The erosions and incipient ulcerations respond better to strong solutions of lactic acid than to any other application. Creosote 20 per cent. in albolin, pyoctannin and iodoform powder are also effective. It is needless to say that the mirror should guide the hand in all applications.

Intralaryngeal injections often serve well for both the general dyscrasia and local lesions.

Submucous injections have not with me proven satisfactory. The method of scarifying the tumefaction is, I believe, contraindicated. In certain selected cases where the infiltration is localized and accessible, especially in the so-called primary cases, thorough curettement followed by carbolic acid or lactic acid is permissible.

DISCUSSION.

DR. M. P. SCHUSTER, El Paso, Tex.—I am located in a place that is supposed to be inimical to this condition, and I have about fifty cases. The cough and the dyspnea are very great in these cases. While the average expectation of life in tubercular cases has been given as three years, laryngeal tuberculosis reduces it to two years. There is a premonitory stage without laryngoscopic symptoms. I have seen two cases in which I was sure tuberculosis was coming on, but I could not establish this by microscopic or laryngoscopic examination. Later the trouble became manifest. In a young man the only manifestation was that he would have a severe spell of coughing, resembling the staccato cough of whooping cough. Sometimes its intensity would lead to vomiting. I was very much gratified to find this fact emphasized in Brouardel's "Traité de Médecine," that a cough with only a small amount of expectoration, accompanied often by vomiting, should lead one to suspect tuberculosis. I have the impression from the literature and my own experience that there is very little primary tuberculosis in the larynx. If it is present it does not produce those infiltrated and deeply ulcerated spots but only little nummular ulcerations that are more amenable to treatment. I was glad to hear Dr. Briggs state that the appearance is hyperemic, for the books often say it is anemic, and my experience is that it is more often hyperemic. The dysphagia comes on most frequently when there is involvement of the posterior periphery, especially the club-shaped infiltration of the arytenoid bodies and also in the infiltration of the interarytenoid fold. After treating patients for four years and trying to avoid local treatment, I have come to the conclusion that we had better treat locally because there is considerable relief secured. For instance, in dysphagia, the dusting with orthoform will enable patients to take their meals. I would like to know Dr. Briggs' proportion of cures. In the literature and in my own experience cures are exceptional. The ulcerated cases are more amenable to treatment than the cases with unbroken surface. You can cure up an ulcer with the persistent use of lactic acid and the curette, usually, but it is not a cure of the laryngeal trouble, for it recurs somewhere in the larynx. The most hope of absolute cure may be entertained where the lung process has stopped definitely.

DR. H. H. BRIGGS—Of course, in the strictest sense of the word, I believe no case is cured. But with close observation and control of every detail one may enable a patient to live almost indefinitely—at least in many cases, for a number of years. In such cases there usually remains cicatricial tissue, tumefaction or tuberculomata, which under lowered vitality and unfavorable conditions may break down.

Dietetics.—The feeding of patients is really as important, if not more important, than the drugging; yet the majority of medical students have to learn their dietetics in the school of bitter experience. The physician must utilize better the so-called forces of nature, and see to it that all the details of the patient's food and environment work for recovery.—*Jour. Kan. Med. Society.*

THE VASOMOTOR SYSTEM OF THE PULP.*

EUGENE S. TALBOT, M.D., D.D.S.
CHICAGO.

In 1733 Stephen Hales[1] first published the idea that small arteries changed their caliber. He devised the following ingenious experiment: Tying a brass tube into the aorta of a dog and employing a head pressure equal to the normal aortic tension he injected water and measured the outflow per minute from the divided vessels of the intestines. He found that cold water diminished the flow, while hot water increased it. He also showed (by the action of drugs) that one set of agents contracted the vessels and lessened the outflow, while another set widened the vessels and increased the flow.[2]

The chief dominating center of the non-striped muscles of the arterial system with motor nerves (vasomotor, vasoconstrictor, vasohypertonic) lies in the medulla oblongata. The nerves which pass to the blood vessels are known as the vasomotor nerves. Without mentioning the experiments which have been made, I might say, in a general way, stimulation of this nerve center causes contraction of all the arteries, resulting in great increase of the arterial blood pressure and swelling of the veins of the heart. Paralysis of this center causes relaxation and dilation of all the arteries, resulting in an enormous fall of the blood pressure.[3]

The sympathetic nerves consist of two chains of ganglia, one on each side of the spinal cord. Their function is to stimulate the viscera, glands, heart, blood vessels and unstriped muscles of the body generally.

There are four small ganglia[4] connected with the fifth nerve: the ophthalmic, sphenopalatine, otic and submaxillary. Each has three roots derived from motor, sensory and sympathetic nerves, respectively, and varying members of branches of distribution. These cells are multipolar, thus resembling the cells of sympathetic ganglia and differing from those of the ganglia of the posterior spinal nerve roots and gasserian ganglion.

Each ganglion is a reddish-gray color, soft in consistence but enclosed in a strong fibrous sheath. It is connected above and below by an ascending and a descending trunk and with at least one spinal nerve by one or two communicating branches. Each ganglion distributes different branches which either directly or through the intervention of a secondary plexus supply blood vessels.

The second or superior maxillary division of the fifth pair of nerves gives off the posterior superior, middle superior and anterior superior dental nerves. These three nerves form a plexus and loops of filament which pass to the tips of the roots to form the dental pulp. The third division of the fifth, the inferior maxillary, a mixed sensory and motor nerve, enters the inferior dental canal, passing forward toward the symphysis menti supplying branches to the teeth and gums.

The gasserian ganglion receives filaments from the carotid plexus of the sympathetic. Connected with the fifth are the four small ganglia already mentioned which form the whole of the cephalic portion of the sympathetic. With the first division is connected the

ophthalmic ganglion, with the second submaxillary ganglion. All the four receive sensitive filaments from the fifth, motor and sympathetic filaments from various sources. The ganglia are also connected with each other and the cervical portion of the sympathetic.

According to the "American Text-Book of Physiology," the vasomotor apparatus consists of three classes of nerve cells.[5] The cell bodies of the first class lie in sympathetic ganglia, their neuraxons passing directly to the smooth muscles in the wall of the vessels; the second are situated at different levels in the cerebrospinal axis, their neuraxons passing thence to the sympathetic ganglia by way of the spinal and cranial nerves; the third are placed in the bulb and control the second through interspinal and intercranial paths. The nerve

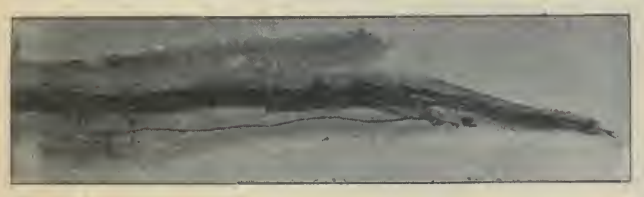

Fig. 1.—Nerve fibers torn from main nerve trunk and entering the canal through the apical foramen. ×50.

cells of the first class lie wholly without the cerebrospinal axis, the third wholly within, while the second is partly within, partly without, and binds the remaining two together.

The vasomotor fibers for the face and mouth have been found in the cervical sympathetic by Dastre and Morat, leaving the cord[6] in the second and fifth dental nerves and uniting (at least for the most part) with the trigeminus by passing, according to Morat,[7] from the

Fig. 2.—Bundles of nerves in the pulp showing vasomotor system. Nerve fibers encircling an artery showing terminals. ×50.

superior cervical sympathetic ganglion to the ganglion of Gasser and thence to the fifth nerve. The nerves of the cerebrospinal system, with the exception of the olfactory, are medullated nerves.

The vasomotor nerves are axis cylinder processes of the sympathetic ganglion cells. They follow for a time the course of the corresponding spinal nerves. Intermingled with the medullated fibers are always found gray or non-medullated fibers. According to Schäfer,[8] these fibers frequently branch; the medullated fibers rarely do except near their termination. The sympathetic nerves are largely made up of these fibers as they approach their peripheral distribution and possess a thin medullary sheath.

From what has been said it will be seen the intimate relation of the fifth nerve is as a motor nerve in mastica-

tion and a sensory nerve to the great surface, both external and internal, which belongs to the face and the anterior part of the cranium. From its great size and the large portion of the medulla with which it is connected, there can be no question but that its sympathetic and vasomotor connection is established.

The nerve trunks as they pass through the lower jaw are made up of nerve fibers gathered together into bundles or funiculi, held together by connective tissue and

5. By "nerve cells" is meant the cell body, with all its processes, namely, the neuraxons or axis cylinder processes and dendrites or protoplasma processes.

called the perineurium. The connective tissue which unites a number of the bundles or funiculi is called epineurium. The cut ends under the microscope resemble very much the end of an ocean cable; the wires representing the nerve fibers, and the rubber covering the connective tissue sheaths.

Fig. 5.—Bundles of nerves in the pulp showing the vasomotor system. Five arteries with nerve fibers running lengthwise, also cross and long section of artery with nerve fiber around it. Thickening of arterial walls showing terminal nerve fibers. ×50.

From this nerve trunk smaller medullated nerve fibers are given off at the nodes of Ranvier which pass up and into the apical foramina of the roots of the

Fig. 6.—Bundles of nerves in pulp showing vasomotor system. Nerve extending along the arterial wall. At right angles may be seen the muscular coat of an artery filled with terminal nerve fibers. ×60.

teeth. Sometimes there are two and again three or ten to twenty-five nerve fibers entering the foramina. The number depends on the size of the opening. In my paper last year on "The Evolution of the Pulp" I demonstrated that in animals whose teeth were in continuous eruption during the life of the animal the pulp was larger at the opening than in the pulp chamber. In ascending to man the second teeth have small openings, especially later in life. In the very nature of things as the root calcifies, especially in exostosis, the openings grow smaller. The number of nerves entering the foramina, then, will depend on the size of the apical opening.

In a general way, the motor, sensory and the sympathetic nerves have been traced from their source to the roots of the upper and lower teeth. Text-books demonstrate the peripheral end organs to other structures of the body. In no case (to my knowledge) has

Fig. 7.—Bundles of nerves in pulp showing vasomotor system. Crosscut section showing ends of nerve fibers, also nerve encircling crosscut artery. ×25.

Fig. 8.—Bundles of nerves in the pulp showing the nervous system. These nerves extend to the odontoblastic layer. Small fibers running below and to the odontoblasts forming a nerve plexus. ×50.

the character of the nerves of the pulp been demonstrated.

At the meeting of this Section last year Dr. Vida A. Latham, in a paper, "Résumé of the Histology of the Dental Pulp," showed the nerve supply to the pulp in different forms and also one illustration of the vasomotor system of the pulp. Part of our special work in the laboratory this year has been to demonstrate the character of the nerves of the pulp.

Pulp study has been conducted by Dr. Latham and myself in different laboratories for the past four years. For this work teeth have been collected each day to the number of over 4,000. These have been cracked open and over 2,000 specimens of pulps have been placed in different fluids ready for cutting, staining and mounting for the microscope. All the different methods of preparation of nerve tissue have been used as reported by Dr. Anderson in a paper, "Notes on Pulp Technic."

The nerve fibers, after leaving the main trunk in the jaw, evidently enter the apical foramina in single nerve bundles. In many cases, these nerve bundles continue the entire length of the pulp without branching. On the other hand, the branching in many cases begins after the trunk nerves have passed through the apical foramina. In Figure 1, when the tooth was extracted the pulp protruded from the end of the root, the opening being large. In this illustration the nerve fibers are shown from the inferior dental nerve extending through the apical foramina in the root canal of the tooth. These seem to run in a bundle or funiculi with the exception of one fiber which is isolated at the root. Figure 2 shows bundles of nerve fibers loosely arranged running in different directions. Between these bundles may be seen many single nerve fibers running in all directions. In the center of the field is an artery cut crosswise with terminal fibers encircling it two-thirds around. Figure 3 beautifully illustrates the vasomotor nerves in their relation to the blood vessels. The blood vessels and nerves run in the same direction. In the center of the field may be seen four arteries. Nerve fibers are notably running the entire length between, but they cross and recross at different localities. Nerve fibers in bundles and singly cover the entire field. Figure 4 shows bundles of fibers with many single fibers throughout the field. In the center may be seen an artery cut lengthwise branching in two directions. The most interesting of all, however, is an artery cut crosswise with vasomotor terminal nerves encircling it. Figure 5 demonstrates the vasomotor system more thoroughly. In the center of the field may be seen nine arteries cut lengthwise and one cut crosswise. Bundles of nerve fibers run between the arteries and along the arterial walls. Nerve fibers are seen crossing and recrossing the arterial walls, sometimes in bundles and again in single terminal fibers. In the cross-cut artery a nerve fiber may be seen almost encircling it. Figure 6 shows enlarged artery cut lengthwise, while just below it may be seen an artery running toward it at right angles. In this artery only the outer surface is seen. In both arterial coats terminal nerve fibers are well shown. Figure 7 shows the ends of the nerve cut crosswise. An artery may also be seen with a nerve encircling it. Figure 8 illustrates the crown end of the pulp with a bundle of nerve fibers which have extended intact the entire length of the pulp and is distributing its fibers throughout the odontoblastic layer.

In consideration that the blood vessels and nerves pass through the pulp in a wavy direction and not in straight lines, to have been able to obtain so many beautiful specimens showing so clearly and distinctly the vasomotor system is fortunate.

I am under obligations to Dr. Ludvig Hektoen for verifying these illustrations and to Dr. Martha Anderson for valuable services.

DISCUSSION.

Dr. M. H. Fletcher, Cincinnati—The nerve distribution of the pulp is a subject that has been greatly neglected, and it is a matter of great pleasure to know that it has been taken up by such physicians as Drs. Talbot and Latham, because through these studies one may be able to find out why the pulp is so delicate in its tendency and recedes so easily from any attempt at investigation. The Doctor's work on the anatomy and distribution of the nerves about the vasomotor system will undoubtedly result in knowledge on points now obscure.

Dr. T. E. Constant, Scarborough, England—From clinical observation I have for some years been under the impression that the so-called odontoblasts have more to do with the vasomotor system than with dentinification. In my opinion, they have very little to do with the formation of dentin, excepting so far as regulating the blood pressure. They undoubtedly assist, but not in the direct manner in which most English dental anatomists have described.

Dr. T. L. Gilmer, Chicago—We are greatly indebted to Dr. Talbot for this work, and we must all be pleased with the success he has achieved. The facts are plainly shown by the photographs.

Dr. G. F. Eames, Boston—One can take clinical advantage of the idea Dr. Talbot has expressed. For instance, there is no place in the body where we can see the control of the nervous system over the tissues as much as in the nose. I believe that in many inflammatory conditions of the pulp we may control these conditions in proportion as we understand what treatment will influence the general nervous system. I have had a patient say: "When I am tired I have a pain in my tooth." I hardly realized at the time what that meant, but I can see now how exhaustion of the nervous system will so influence the control of the blood supply in that organ that it will be paralyzed and admit blood, and pain be caused. I can see also how in a subacute inflammatory condition a person whose nervous system has been exhausted may acquire a chronic state of inflammation in the pulp by these fibers being paralyzed, so that the blood vessels themselves become permanently stretched. Therefore these demonstrations have a clinical value.

Dr. Jules J. Sarrazin, New Orleans—I agree that the knowledge may be of great usefulness in a better understanding of physiologic pulp conditions. The paper reveals thorough research, but, in my opinion, we are not yet able to fully profit by the work, because we must arrive at a greater elucidation of the subject before the deductions which may be drawn therefrom may guide practical therapeutic application in the field of pathology.

Dr. Eugene S. Talbot—Six years ago, it occurred to me that a symposium each year on the dental pulp would be a valuable contribution. About thirty years ago I realized that there were conditions that assisted in the decay of the teeth other than those brought out by Professor Miller. My studies in degeneracy in this country and Europe have taught me that in degenerates decay of the teeth takes place more rapidly than in healthy individuals. The same thing is true in families of four or five children where all but one child is healthy. The teeth of the degenerate child decay more rapidly than those of others. I am now taking up the study of the dental pulp or of the nervous phenomena in decay of the teeth. To bring out what has been done in regard to the pulp, men from abroad who are specialists along certain lines have been invited to read or send papers. They have advanced ideas on certain subjects, and while they may not agree with each of us, yet many new and original ideas have been brought out. Such papers create a good discussion, and assist greatly in elucidating facts. My paper to-day, as I have said, covers work of four years. Mr. Constant has rather anticipated me in the work I have now on hand, which, I think, will bring out certain points in relation to the teeth as suggested by him, and I shall present it very soon. Had I undertaken this work ten or fifteen years ago it would have been impossible to have shown the pictures I have, because modern stains have developed an idea of the terminal structures of the nervous system which was impossible years ago.

THE TREND OF GYNECOLOGIC WORK TO-DAY.

A. PALMER DUDLEY, M.D.

Professor of Gynecology, New York Post-Graduate Medical School, New York; Professor of Gynecology, Dartmouth Medical College, Hanover, N. H.; Surgeon to Harlem Hospital.

NEW YORK.

(Concluded from p. 1452.)

EDWARD J. ILL, NEWARK, N. J.

Total number of cases	66	Left tube removed	25
Left ovary diseased	34	Right tube removed	24
Right ovary diseased	28	Appendectomies	3
Left tube diseased	40	Herniotomy (femoral)	1
Right tube diseased	33	Ventrosuspensions	20
Left ovary resected	13	Vaginal sections	2
Right ovary resected	14	Pregnancies	8
Left tube resected	14	Married	57
Right tube resected	6	Average age	30
Left ovary punctured	3	Recovered	35
Right ovary punctured	1	Improved	12
Left tube opened	4	Not improved	2
Right tube opened	4	Died	1
Left ovary removed	21	No report	16
Right ovary removed	17		

Dr. Ill's report shows most gratifying results, and his average of pregnancies reported (9 in 50 cases) compares favorably with my own.

JOS. E. JANVRIN, NEW YORK.

He quotes no statistics, but expresses a firm belief in the wisdom of preserving the function of menstruation as indispensable to the well-being of his patients.

CHAS. JEWETT, BROOKLYN.

Dr. Jewett, in a material of 62 cases of conservative surgery of the ovaries, etc., knows of but 3 cases of pregnancy occurring subsequently. He believes, especially in the case of young women, that any portion of the ovary which appears to be sound to the naked eye should be allowed to remain.

JOSEPH TABER JOHNSTON, WASHINGTON, D. C.

Dr. Johnston[3] advocated the conservative treatment of the diseased ovary before the Southern Surgical and Gynecologic Association, Dec. 6, 1898.

MATTHEW D. MANN, BUFFALO, N. Y.

Dr. Mann has seen pregnancy follow where the ovaries seemed at the time to be hopelessly diseased; not so with the tubes, however.

W. P. MANTON, DETROIT, MICH.

Number of cases	28	Ovary punctured not stated	4
Married	22	Left tube resected	0
Single	6	Right tube resected	1
Left ovary diseased	13	Left ovary removed	2
Right ovary diseased	23	Right ovary removed	5
Ovary diseased, not stated	4	Left tube removed	2
Left tube diseased	2	Right tube removed	4
Right tube diseased	5	Pregnancies	2
Left ovary resected or punctured	15	Cured or greatly improved, all but 2 or	3
Right ovary resected or punctured	20		

Dr. Manton reports a most interesting case in which he found a third ovary embedded in the vaginal wall at the cervico-vaginal junction. The cysts in this third ovary were removed by vaginal section. In nearly every case reported other plastic work on the genital tract was performed.

His results with two or three exceptions were entirely satisfactory.

SIMON MARX, NEW YORK.

Dr. Marx writes of an interesting case of pregnancy after practically all ovarian tissue had been removed in two consecutive operations.

ROBERT T. MORRIS, NEW YORK.

Dr. Morris has sent me a valuable communication on conservative surgery of the ovary, but as he deals almost exclusively with the question of implantation, I can hardly make use of it in this connection.

3. THE JOURNAL A. M. A., Dec. 17, 1898.

H. P. NEWMAN, CHICAGO.

Total number of cases	86	Required secondary intervention, per cent	20
Resection of ovaries	86	Pregnancies (3 abortions)	8
Recovery, per cent	60	Suspension of uterus or ovaries, per cent	50
Improvement, per cent	20		

Although guarded in his opinion, Dr. Newman is in favor of conservative work, and his report shows most gratifying results.

RICHARD C. NORRIS, PHILADELPHIA.

Total number of cases	42	Relieved by second operation, per cent	15
Controlled by statistics	28	Unimproved, per cent	35
Symptomatic recovery, per cent	20	Pregnancies (in 10 cases)	2
Improvement, per cent	30		

Dr. Norris has but recently read a paper on conservative surgery of the uterine appendages before the Lancaster County (Pa.) Medical Society. His experience in this field extends over some 8 years. The material is confined to hospital work.

Generally speaking, he is the most pessimistic of my correspondents in regard to conservative work. The results, he says, are often discouraging. There appears to be no definite relationship between the amount and character of intervention and the final result, which makes prognosis extremely difficult.

It must be borne in mind that Dr. Norris' views are based on a rather small material—28 cases.

C. D. PALMER, CINCINNATI.

Eighty-eight operations of bilateral oöphorectomy performed since June 30, 1899. All were hospital cases but 5.

Disease: Chronic catarrhal with some interstitial salpingitis, the vast majority of gonorrheal origin, a few only being septic.

Never operates on other than inflammatory cases.

Mortality 4 per cent.

Knows of no subsequent pregnancies.

In 3 cases menstruation persisted for some months and perhaps longer.

Abdominal section, usually preceded by curettage of uterus. Vaginal section in endometritis followed by salpingitis, but rarely did more than wash out cavity of lower peritoneum.

Dr. Palmer, in summing up the results of his work places himself on record as in favor of conserving the appendages, but insists that all the minor plastic work, including curettage of the uterus and even posterior vaginal section for drainage, should first be resorted to.

WILLIAM M. POLK, NEW YORK.

Dr. Polk has had experience with a very large number of conservative cases. According to his recollection, he has operated 273 times. In the absence of documental evidence, his figures are not counted with the actual totals. He only knows of 5 cases of pregnancy. Most of his material consists of charity cases from Bellevue Hospital.

In 1886 Dr. Polk read a paper[4] before the Society of Physicians and Pathologists at Washington in which the subject of conservatism was discussed.

M. F. PORTER, FORT WAYNE, IND.

Number of cases, over	50	Pregnancy	0
Resection or puncture of ovaries and tubes, per cent.	100	Results satisfactory; better in ovarian work.	

JOSEPH PRICE, PHILADELPHIA.

In a report of 100 cases of resection of the ovary it is stated that pregnancy followed in a good percentage of the cases. In some instances only a third or fourth

4. American Practitioner, vol. 1, and Med. Record, Sept. 18, 1886.

of the ovary was left. Dr. Price declines to resect the tubes, preferring to remove them entirely.

EDWARD REYNOLDS, BOSTON.

Total number of cases	8	Right tube resected	3
Left ovary diseased	3	Right tube punctured	1
Right ovary diseased	3	Left ovary removed	3
Ovary diseased not stated	2	Ovary removed not stated	1
Left tube diseased	6	Right ovary removed	3
Right tube diseased	6	Left tube removed	1
Ovaries resected	0	Right tube removed	2
One ovary punctured (not stated which)	1	Pregnancy	0
Left tube resected	5	Recovery (data in 3 cases only)	3

Dr. Reynolds holds the record with us in this country as a successful operator in cesarean section. The report of his cases does not represent more than 10 per cent. of the work he has done, but it is evidence sufficient that he is a thorough believer in conservatism in appropriate cases.

E. C. SAVIDGE, NEW YORK.

Number of cases	large	Pregnancies	4
Implantations (abdominal operations), per cent	100	Results, very gratifying in all respects but pregnancy.	

F. F. SIMPSON, PITTSBURG, PA.

Total number of cases	53	Right salpingostomy	3
Right salpingoöphorectomy	11	Left salpingostomy	2
Left salpingoöphorectomy	10	Ventrosuspension, etc	33
Right ovary resected	6	Pregnancies	5
Left ovary resected	7	Appendectomies	7

A. LAPTHORN SMITH, MONTREAL, CANADA.

Left ovary diseased	14	Right tube removed	12
Right ovary diseased	16	Ventrosuspensions	2
Left tube diseased	17	Results:	
Right tube diseased	14	Good	12
Left ovary exsected	3	Pregnancy	2
Right ovary exsected	10	Unsatisfactory	4
Left tube exsected	0	Unknown	1
Right tube exsected	1	Number of cases	17
Left ovary removed	9	Married	12
Right ovary removed	5	Single	5
Left tube removed	16	Average age, under	30

I. S. STONE, WASHINGTON, D. C.

Left ovary diseased	69	Ventrosuspensions	36
Right ovary diseased	69	Appendectomies	6
Left tube diseased	18	Pregnancy	1
Right tube diseased	31	Myomectomies	6
Left ovary exsected	12	Vaginal sections	3
Right ovary exsected	12	Vaginal suspension	1
Right ovary exsected	19	Hysterectomies	2
Left tube exsected	2	Cured	44
Right tube exsected	5	Relieved	40
Left ovary removed	26	Not relieved	1
Right ovary removed	29	Average age	28
Left tube removed	15	Married	53
Right tube removed	26	Single	32
Left ovary punctured	33	Number of cases	85
Right ovary punctured	24		

Dr. Stone is averse to doing conservative work on infected cases, but believes most emphatically in leaving any portion of healthy ovarian tissue in the young.

MAGNUS A. TATE, CINCINNATI.

Total number of cases	2	Right ovary resected or punctured	1
Left ovary diseased	2	Ventrosuspension	1
Right ovary diseased	1	Pregnancy	0
Left ovary resected or punctured	2	Recoveries	2

JOHN F. THOMPSON, PORTLAND, ME.

Dr. Thompson reports one case in which both ovaries were cystic. The left was removed and the right resected. The woman subsequently became pregnant and gave birth to twins.

ALBERT VAN DER VEER, ALBANY, N. Y.

Ovarian surgery is much more satisfactory and attended with better results than tubal surgery.

H. N. VINEBERG, NEW YORK.

Total number of cases	106	Operation failed	10
Vaginal sections	34	Died	1
Laparotomies	72	Cured or much improved	95
Pregnancies	12		

Dr Vineberg's report evidences the fact that this work can be done per vagina with as good results as by the abdominal route, which leaves this question still open for discussion.

EDWIN WALKER, EVANSVILLE, IND.

Total number of cases	6	Right ovary removed	0
Left ovary diseased	5	Left tube removed	5
Right ovary diseased	5	Right tube removed	3
Left tube diseased	5	Ventrosuspension	1
Right tube diseased	5	Pregnancy	1
Left ovary resected	1	Average age	30
Right ovary resected	4	Cured	2
Left ovary punctured	1	Improved	1
Left tube resected	1	Not improved	1
Right tube resected	2	Too recent for results	2
Left ovary removed	3	Married	6

T. J. WATKINS, CHICAGO.

He knows of several cases of pregnancy following ovarian surgery, but has kept no records.

J. H. CARSTENS, DETROIT, MICH.

Dr. Carstens of Detroit, although he did not give me statistics of his work, expressed his opinion in his characteristic and candid manner concerning this work. He agreed in the main with Dr. Wheaton, that in suitable cases it was wise to leave portions of the ovaries in position, in order to prevent as much as possible the reflex conditions that follow such work.

C. A. WHEATON, ST. PAUL, MINN.

Dr. Wheaton sums up the whole question in such a concise and straightforward manner that I desire to quote his letter in full:

I have before me your favor of Nov. 19, etc. . . . In our hands conservatism has proven a great boon to suffering femininity. I regret that our cases are not so classified that they can be of service to you. We have repeatedly made operations on the pelvic organs of the female, often removing the uterus and leaving the ovaries; often removing the tubes and leaving the ovaries and the uterus; often removing both tubes and leaving one ovary; often removing a tube on one side and an ovary on the other; often removing portions of ovary or tube, and I have yet to see the case in which I have regretted that sort of conservatism. It seems to me that the all-important question, independent of every other consideration, is the leaving ovarian tissue enough to preserve the sexual integrity of the woman. When I say "sexual integrity" I mean in its physiologic sense. A woman, deprived of her ovarian machinery, to my mind, is as much a defective as the eunuch, or the children born without any of the organs which go to make up the perfectly developed animal.

I regret that I am unable to give you a series of cases classified, but I have never kept a consecutive record of my work.

H. T. WILLIAMS, ROCHESTER, N. Y.

Total number of cases	250	Right ovary diseased	85
Available for statistics	155	Left ovary diseased	60
Ventrosuspensions	52	Pregnancies	25
Appendectomies	30		

SUMMARY.

An analysis of the preceding tables gives the following results:

TOTAL NUMBER OF CASES.

Baker, Boston	1	Ill, Newark, N. J	66
Boldt, New York	82	Manton, Detroit	28
Brettauer, New York	31	Marx, New York	1
Brothers, New York	50	Newman, Chicago	86
Burrage, Boston	187	Norris, Philadelphia	42
Clarke, Cambridge, Mass.	13	Palmer, Cincinnati	88
Coe, New York	5	Porter, Fort Wayne, Ind.	50
Cragin, New York	33	Price, Philadelphia	100
Cumston, Boston	47	Reynolds, Boston	8
Douglas, Nashville, Tenn.	30	Simpson, Pittsburg	53
Dudley, New York	269	Smith, Montreal, Canada	17
Earnest, Atlanta, Ga	8	Stone, Washington, D. C.	85
Ferguson, Chicago	75	Tate, Cincinnati	2
Frederick, Buffalo	125	Thompson, Portland, Me.	1
Goffe, New York	115	Vineberg, New York	106
Goldspohn, Chicago	97	Walker, Evansville, Ind.	6
Gordon, Portland, Me.	2	Williams, Rochester, N. Y.	155
Griffith, Kansas City, Mo.	4		
Humiston, Cleveland	5	Total	2168

This number could be considerably increased by including figures furnished from memory, etc., without proper documentation.

AVERAGE AGE.

In but few reports is the age recorded. From the statistics submitted by Boldt, Ill, Smith, Stone and

Walker, it appears that the average age of patients is slightly below 30 years.

MARRIED OR SINGLE.

Most reports are also defective in this respect. Out of 405 cases reported by Cragin, Dudley, Ill, Smith, Stone and Walker, 315 are known to have married—nearly 80 per cent.

An analysis of the recorded lesions, operations, etc., reveals certain data of interest.

There is a slight preponderance of diseases on the left side, 722 diseased ovaries as contracted with 702 on the right side; while the tubes show a similar preponderance, viz., 322 as against 308. While these differences are slight, they are probably not due to chance, but should be susceptible of explanation on circulatory grounds (absence of valves in left spermatic vein, pressure of fecal matter in sigmoid flexure on this vein, etc.).

The figures show that conservative operations were performed on the left ovary 370 times, while the organ was removed 281 times. The corresponding figures for the right ovary are 384 conservative and 241 radical operations. Hence the totals comprise 754 conservative and 522 radical operations. This excess of conservative intervention is bound to increase in the future.

When we come to operations on the tubes the figures for conservative and radical intervention are found to be reversed. Thus on the left side there were 127 complete extirpations of the tube against 96 resections, punctures, salpingostomies, etc. The corresponding figures for the right tube are 138 radical and 83 conservative operations. The totals are, therefore, 265 extirpations and 179 partial operations. A number of surgeons are outspoken against conservative work on the tubes, and it is difficult to forecast the future in regard to the character of intervention on the tubes accompanying conservative operations on the ovaries.

In regard to the statistics on uterosuspensions, appendectomies, etc., given in my tables, it is only necessary to emphasize the fact that multiple operations, including plastic surgery of the genital tract, must frequently be performed in connection with conservative surgery of the ovaries.

In regard to results, two classes must be considered: The general outcome of the operation, and the preservation of sex. The primary mortality is quite insignificant, amounting to but about 1 per cent.—9 cases in nearly 2,200 (2,168). It is possible that some of these few may not be attributable to the operation proper. In regard to the ultimate success of the intervention the tables show not over 10 per cent. of failures, and many of these were corrected by second operations, which, however, would be classed as radical intervention. The overwhelming majority of my correspondents express themselves plainly in favor of conservatism on general principles, the very few exceptions being duly noted under individual reports.

In regard to the preservation of sex, we do not find many statements as to the persistence of menstruation. It is to be regretted that operators can not control their cases in this respect, but the difficulties are almost insurmountable. The question of subsequent pregnancies can be answered very satisfactorily. Despite the great difficulties attending the following up of these cases, we have positive proof that at least 10 per cent. of the women who make up by statistics became pregnant. When we bear in mind that many of these women doubtless do not desire offspring, and that quite a number

Fig. 1.—Case 1. Showing appearance after tube was amputated and ovary sewed up. The two sides were alike.

had both ovaries removed (Dr. Palmer's cases), the percentage must be regarded as remarkable; for there is every reason to believe that many pregnancies were not located, while in many other cases the operations were of such recent date that pregnancy is likely to develop in due time.

I have not thus far mentioned the many cases of deformed and twisted conditions of the tubes on which we can do conservative work. Bearing in mind its anatomy

Fig. 2.—Case 2. Anterior view showing remaining healthy portion of right ovary.

and surroundings, it is not to be wondered at that the tube is subjected constantly and especially at the time of menstruation, to congestion and thickening, as a result of displacement, or pressure, which will cause a temporary, if not a permanent, closure of some portion of its lumen. See plates of Dr. Ferguson and myself. Conditions such as these of the tube can be relieved by conservative work.

The "surgical menopause," so to speak, has become such a fruitful source of revenue to those in our profes-

sion who are eminent in their practice as nerve specialists, and the records of their work evidence such an accumulation of various nervous manifestations consequent on the total removal of the uterus and appendages; or (even to put it mildly), a partial removal of these organs, that it behooves the operating surgeon who is yearly doing a large amount of this work, to bear in mind, that possibly he may be sowing the seeds of disease in some other part of the body while he so skilfully removes that which he considers to be local.

Having had this fact many times so forcibly brought to my mind by the return of patients with these nervous symptoms, so prominent as to be a constant source of annoyance to them, I have been forced in defense of myself, and for the benefit of my patients, to give serious thought and study to this condition from the nervous standpoint, and rather than attempt to give you my own opinion from a clinical standpoint, something that you might not feel I was justified in offering to you from my knowledge alone, I much prefer to quote to you from the experience of one of our best-known teachers on nervous diseases in New York, or even the United States—Dr. Graeme Hammond, professor of nervous diseases in the Post-Graduate Medical School. He says:

The more organs removed, the more pronounced the nervous symptoms are likely to be. The results most likely to follow, in mild cases, are those of neurasthenia. In more severe cases, from mild to severe grades of hysteria and dementia. In still others we see more severe mental disturbances, such as development of paranoia, melancholia and a mild grade of dementia, with severe hot flashes.

These hot flashes are very common, even after the removal of parts of the pelvic organs, not necessarily the removal of all of them; say simply the uterus or one ovary. They get neurasthenic symptoms, insomnia, depression of spirits, with crying spells, irritability, inability to apply the mind to ordinary occupations, flushes of the face, etc. These flushes are due to vasomotor paralysis, having its origin in the generative organs. That is probably cerebral, due to temporary paralysis of the sympathetic system.

There may be, on the other hand, attacks of coldness of the feet or hands, which are the result of the spasmodic condition of the blood vessels due to irritation.

This paralysis or irritation of the sympathetic system results unquestionably from the surgical operation. What that operation really does; how the removal of those organs affect the brain, whether it is from the cessation of the menstrual function or not, I am not quite so clear.

In answer to Dr. Hammond's query concerning just how the operation should interfere with the nervous centers it is only necessary to call the attention of those of you who are daily operating to the normal anatomy of the pelvis, its lymphatic, its sympathetic and its vasomotor nerve supply, and then ask you if it can be possible to remove a section of an electrical supply to the different parts of the body, emanating from the brain, to cut out a section of its conductors on both sides of the body, and have the work go on as before until such time as that removal can be repaired by nature. It is only a homely comparison between the machinery of the body and the machinery of electricity and mechanics, but it seems to me only reasonable to suppose that if it produces defective action in the latter (mechanics) it must also do the same to the body.

It would seem as if the ovaries and probably the testicles add something to the system which is necessary for that individual's complete development, and by removing the ovary or testicle, you deprive the system of something which causes a perversion of nutrition. There is a progressive failure of sexual orgasm from coitus, with the progressive changes in the nerves which supply the clitoris, but whether there is a failure of desire or not would be another matter, because desire is purely cerebral. As the clitoris degenerates the power of experiencing the orgasm will diminish little by little

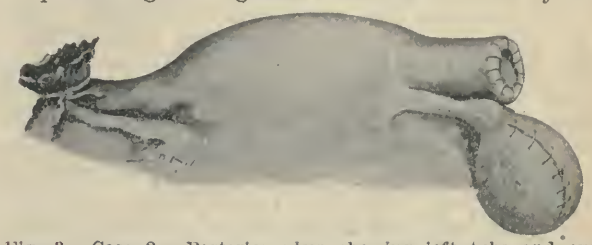

Fig. 3.—Case 2. Posterior view showing left tube and ovary removed and healthy portion of right tube and ovary seen in Figure 2 sewed up.

until it finally fails altogether. These women for a time have erotic dreams showing the desire which they can not appease by natural cohabitation. In a little while they stop.

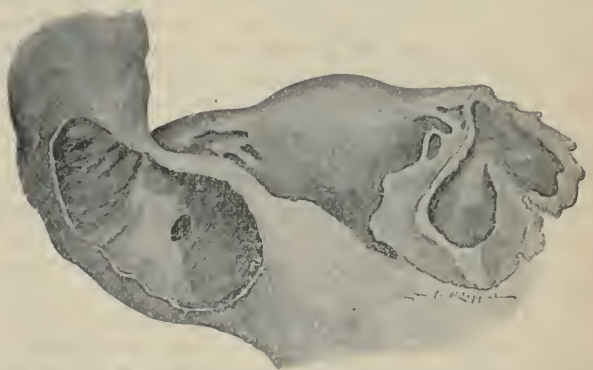

Fig. 4.—Case 2. Posterior view showing fistula from tube to bowel, and showing Figure 2 opened.

There are some women who are abnormally sexual, and in such women the power of experiencing the orgasm lasts much longer than it does in the average woman. In some rare instances the sexual appetite is

Fig. 5.—Conservative work on the adnexa. (Drawn for Dr. A. H. Ferguson, Chicago.) A. Bisection of ovary. B. Shortening ovarian ligament. C. Salpingostomy and the closed end removed. D. Left tube obstructed proximally; into the open fimbriated extremity is inserted the nozzle of an inflator, by which an attempt is made to force air through the tube.

greatly increased after removal of the uterus and its appendages.

There are occasional cases which are unable to experience the orgasm and who turn from coitus with ter-

ror on account of the suffering which they undergo whenever coitus is attempted. These patients are, of course, greatly relieved by the removal of those organs which have caused their suffering. Sometimes in such cases as these the sexual desire is greatly increased after an operation and this increase may continue for years.

In some women with a pronounced neurotic history there appears to develop after operations on the pelvic organs a periodical mania in which sexual fury is the pronounced symptom. In such cases there are periods in which the woman indulges in sexual excesses for days at a time, going clandestinely to houses of easy virtue for the purpose; and then there follows a period in which (very often of several weeks' duration) there is little or no sexual desire at all for them, to be followed in its turn by another period of sexual fury. These are cases of recurrent sexual mania, akin to recurrent attacks of dipsomania.

I would say this: that there is little doubt that the removal of the pelvic organs is very prone to induce degenerative cerebral changes in those who are predisposed by heredity to a neurosis. In other words, you take a woman who has a tendency to nervous disease in the family, and who is nervous herself, and that operation may induce paranoia, which might not have developed until the natural menopause at the age of fifty, or might not develop at all.

Reflexes.—In regard to the pain in the back, you can account for that by pressure on the nerve centers in the pelvis.

Constipation.—Simply in those cases where neurasthenia is produced.

Typical Symptoms of Neurasthenia Resulting from this Operation in the Case of a Patient.—Walks with difficulty on account of weakness and pain, the pain being located in both thighs. She has vertigo, insomnia, disagreeable dreams, depression of spirits, crying attacks, irritable, fretful and a feeling of pressure in the head, and headache; flatulency, dyspepsia and constipation. Now, these are typical symptoms. In a good many neurasthenic subjects there is a great degeneracy of mind because they think that people can tell they have had this operation done by looking at them, and they get depressed from that, avoid society and hate to go out. I have seen a number of such cases.

When we remove the testicles from the male, he becomes timid and loses his virility and courage; he becomes fat and gross; there is also a similar change in the animal. The horse has not the health, the virility or the courage of the stallion. Now, simply cutting off his toe would not make this change. There is something vital taken away from him, and the parts taken out constitute something that he especially requires.

With regard to hysterectomy, it is well-known that a woman on whom hysterectomy has been performed loses her sexual desire in about eighteen months therefrom, barring cases I have already mentioned. If it is possible to save the uterus, why not do it? If it is possible to save only half an ovary, save it. If it is possible to save only part of a tube, save it, provided that it is, or can be made, patent. If there is a fibroid in the uterus, remove the fibroid and leave the uterus, in selected cases. If there is a cyst in the ovary, remove the cyst and leave what healthy ovarian tissue you can. You know that this work can be done and that the resected ovary or tube will heal. If there is mild oozing of blood, the pelvic peritoneum will take care of it. This is conservative surgery. May it continue to develop in the future!

THE CAPACITY OF A HUMAN MUSCLE FOR WORK.*

JESSE GEORGE HOLMES,

From the Physiologic Laboratory of Northwestern University Medical School.

CHICAGO.

HISTORICAL REVIEW.

Each year adds its share to the work that is being done by the different investigators in the study of muscular contractions, neuromuscular fatigue and the ability of a muscle to do work. To Mosso[1] must be given the credit of first making investigations with the human muscle. The instrument used by him in his work consisted in a weight and pulley. The muscular power obtained he expressed as weight multiplied by the dis-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. L. Hektoen, F. B. Wynn and W. S. Hall.

tance through which it was raised. Maggiora,[2] Lombard,[3] Treves,[4] Cleghorn and Stewart,[5] Storey[6] and others continued investigations, introducing various modifications into the technic, thereby obtaining results of considerable value and interest.

Thus the original idea and the one followed more or less closely since has been to have the muscle raise and lower a weight successively through a given distance. It was found that a muscle can raise the weight at a regular rate until, as fatigue sets in, the height of the contraction becomes less and the movements become slower and more difficult. The amount which a muscle can do depends on the muscle and the technic used, the rapidity with which it contracts and the weight it has to lift. Among the objections that soon became evident are the following: (1) That the muscle after a short time becomes so fatigued that it can no longer lift the given weight. It can still exert a considerable amount of force, and if a lighter weight be used it can lift it. (2) It is found that only isotonic contractions are possible in the use of the weight ergograph, and that the muscle is under a continuous tension. (3) The greatest tension of the muscle is that required to overcome the inertia of the weight in starting it.

Others, thinking that with the use of the weight the muscle does not work to the greatest advantage, employed the spring. Cattell,[7] Binet and Vaschide,[8] Franz,[9] Hough,[10] Fick[11] and others have used this form quite extensively, but it has not replaced the use of the weight entirely. The advantages of the spring over the weight are the following: (1) The slightest movement made by the muscle can be recorded, whether it is of the isotonic or isometric form. (2) An interval of rest is allowed the muscle between the periods of relaxation and contraction. (3) The inertia is less pronounced. On the contrary, however, Franz[12] says that most of the objections which apply to the weight will also apply to the use of the spring. Thus it may be seen that the introduction of the isometric contraction, a condition not possible with the weight, has added interest to the study of action of a muscle.

GENERAL CRITIQUE.

In answer to the objections to the weight or spring ergograph, it has been mentioned that most of them are objections either to the mechanical construction which might easily be overcome, or to their use in particular problems. But no mention was made to the most serious fault of these methods, viz., that the muscle does not work under conditions which are physiologic. With the weight, the muscle is "loaded," having no interval of rest at any time, while with the spring it is "after-loaded." A large part of the energy expended by either the "loaded" or "after-loaded" muscle is not accounted for, because it is expended either in the form of internal energy or as external work which can not be computed. The loaded muscle, on the one hand, becomes tetanized early, and though the weight tends to stretch it during relaxation and the rest period, the results of such experiments with muscle-nerve preparations of a frog make it evident that the muscle neither relaxes nor rests between contractions after the fatigue sets in. The after-loaded muscle, on the other hand, must be exerting a certain amount of energy in "easing" back the weight to its rest which would otherwise fall back under the influence of gravitation. The cycle of the former is contraction, relaxation with load and stretching. With the latter it is contraction, relaxation with load and rest.

Put in a practical way, the loaded muscle might be explained thus: Let a man lift a twenty-five-kilogram weight from the floor to the table, and without resting it on the table lower it to the floor; but before it touches the floor let him raise it again to the table and repeat until he is exhausted. At no time does he rest from his weight, and fatigue comes on quickly. If, however, in the interval between the lowering and the next lift the weight is allowed to rest on the floor for a few seconds, the muscle will have a chance to recuperate, and he will be able to do more work as the result. This is the condition with the after-loaded muscle.

But neither of these forms of work is used by the muscles in active life. Therefore, any results or conclusions obtained by them under these conditions would be of limited value. What seems to me to be a better form of work might be explained thus: Let a man lift a weight from the floor to the table and leave it there, reach down and lift another and continue. Work is being performed by him only with the lifting of the weight. During the remainder of the time the muscles are relaxed and resting for the following task. Its cycle in work would be contraction, relaxation without load and rest. The muscles expend little or no energy during relaxation and none at all during the rest period. Fick, by means of his *Arbeit-sammler,* has applied this method to the frog muscle. Broca and Richet[13] have made a few experiments on the human muscle. Their work, however, has not been very extensive. Hall[14] applied this idea of Fick to the human muscle independently of Broca and Richet.

The above criticisms may be summarized as follows:

(1) The various forms of the Mosso ergograph "load" the muscle and cause it to exert energy in some form constantly, while work is being accomplished part of the time only.

(2) The spring ergograph "after-loads" the muscle when used to record isotonic contractions and allows rest for the muscle between relaxation and contraction, but not during relaxation.

METHODS.

With a view of overcoming as many of the objections as possible and applying this method of work to the human muscle, Hall's work-adder was devised. A detailed account of the instrument is necessary, as no description of it has ever been made in literature. By it the muscle works only during the actual lifting of the weight. The troublesome inertia is lessened by having the weight made heavy and having it move so slowly that it follows

the action of the finger very closely. Variations are allowed in the size of the weight by changing the leverage.

The objection may be raised that if the weight is of such large size, the finger, when nearly exhausted, will fail to move it, and there will be no record of the energy spent. But that the muscle may work to the full extent, a heavy weight is necessary. There are two kinds of work: (1) One in which the task is very great for that muscle and requires relatively an immense amount of energy to be expended with every effort put forth. This method can last for a short time only when exhaustion follows and a rest is necessary. (2) The other form is that in which the task is considerably below the working capacity of that muscle, and a relatively smaller amount of energy is put forth. The latter can be continued for a much longer time without fatigue necessarily following. Very different results follow the use of these two methods, and the distinction must be recognized when an interpretation of them is to be made. Some have failed to note this difference and considerable confusion has been the result. The formula—distance times weight—expresses accurately the amount of work a muscle can do if the conditions of the muscle itself and those under which it works are taken into account. Another objection is that the energy expended in starting the weights is greater than that to keep it going. This is true of every task and is not a valid objection if taken of every day work. Every object that a laborer lifts requires a greater expenditure of energy to start it than to keep it going. When the task is too great for him, he gets no credit for his work, but he still has energy sufficient for a task that is within his strength. The same principle should be applied to the individual muscle. Hough[15] admitted that "the work of our muscle consists for the greater part . . . in a series of liftings of an approximately constant weight and that this weight is far below the maximum for a given muscle," and also says: "It would be a serious mistake to abandon altogether this type of instrument," viz.: weight ergograph in fatigue experiments.

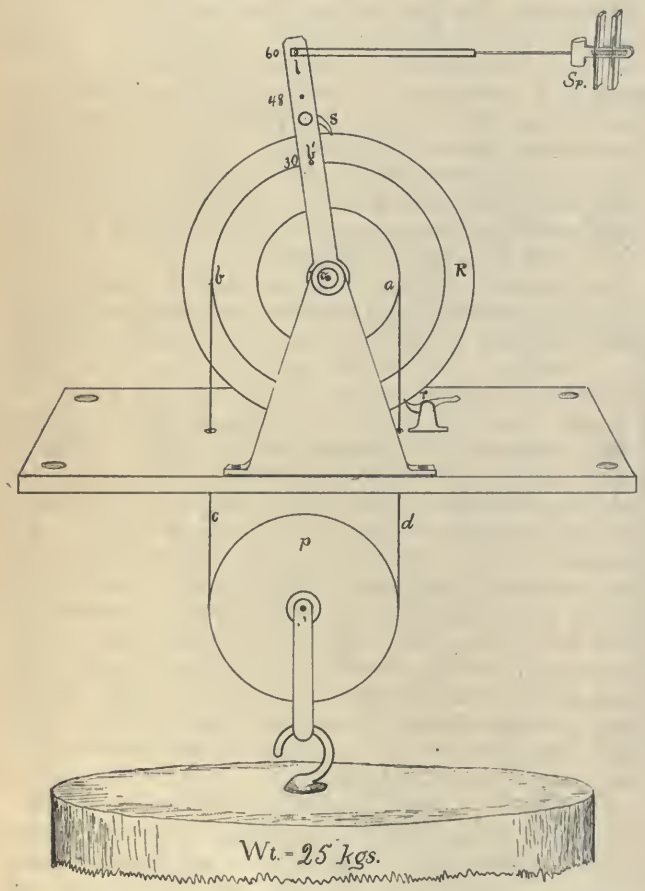

Fig. 1.—Diagram of work-adder. a, Small drum, 36 mm. in diameter; b, large drum, 60 mm. in diameter; cd, wire winding off drum a, around pulley p, and on to drum b; r, ratchet wheel, fixed immovably to both drums (this wheel has a toothed edge not shown in the figure); sp, finger splint or boot, which clamps the two terminal phalanges of the middle finger; r-s, ratchets (r fixed and s movable); l, the lifting or pulling lever, here set to lift at 60 mm. from the center o, thus lifting one-tenth of the weight, 25 kgs., as explained in the text. The splint may be attached to the lever at 48 mm. or at 30 mm.; in the latter case the amount lifted by the finger would be 5 kgs., or 11 pounds. Figure is one-half actual size.

It is true that the muscle under normal physiologic conditions is neither loaded nor after-loaded, as these terms are usually understood. It is not under a constant tension as when it contracts isotonically; it varies its length, differing from the muscle contracting isometrically. "During normal physiologic conditions a muscle does not contract isotonically, but always with a change of tension."[16] Expressed affirmatively, the working muscle expends energy only while it is lifting the weight; it varies its tension and rests between lifts. I have chosen to call a contraction under these conditions "normotonic."

THE WORK-ADDER.

One of the ergographs used in these experiments consists of a weight and a movable pulley suspended by a fine wire (Fig. 1). The two ends of this wire are wound in opposite directions on two drums (*a* and *b*) of different sizes. These drums are fixed on the same movable axis (*o*), and any movement will wind up the wire on one drum while it unwinds from the other. A ratchet (*r*) prevents any turning except in the direction which winds it on the larger drum, thus raising the weight. A pulling lever (*ol*) also rotates freely about the same axis (*o*), and by means of a ratchet (*s*) revolves the drum in the direction which raises the weight. The pulling lever then returns by the aid of a weak spring, with the finger, to its original position and is ready for the next pull. Complete rest is thus obtained for the muscle while it is not actively pulling. The heavy weight with the drums overcome, to a great extent at least, the inertia. The system of levers reduces the actual weight raised to within the power of the contracting muscle and allows for variation in its size.

The leverages are explained thus, as shown in Figure 1: The small drum (*oa*) has a radius of 18 mm. and the larger (*ob*) a radius of 30 mm. Each end of the wire (*c* and *d*), wound on these, supports one-half of the weight or 12.5 kgs. The drums act as levers of different lengths, and as each is supporting 12.5 kgs., the tendency is for the wire around the larger drum to unwind because of the longer weight arm. This movement is prevented by the ratchet (*r*). The exact amount of downward pressure to balance the 12.5 kgs. on (*oa*) is shown by the proportion, 30:18::12.5:x, or 7.5 kgs. But there is a weight of 12.5 kgs. hanging on the lever (*ob*). Therefore, the ratchet is sustaining the difference between 12.5 kgs. and 7.5 kgs, or 5 kgs., and before the weight can be raised this must be overcome. To further reduce this weight of 5 kgs. the pulling lever is used. The power arm (*ol*), which may be varied at will, is 60 mm. long, and the weight arm (*ob*) is 30 mm. long,

15. Cf. pp. 242 to 245.
16. Schaack and Gruber: Human Physiology, p. 188.

the proportion being 60:30::5:x, or 2.5 kgs. Then the actual force necessary to raise 25 kgs. by this instrument is a force in excess of 2.5 kgs. pulling at the distal end of the pulling lever (*l*).

The arm rest consists of a slanting board modeled at the end to fit the hand. That the middle finger might have free movement, a notch was cut in the board. Straps hold the arm, hand and fingers in place. The first, third and fourth fingers are bent over the end of the rest and held in the partly flexed position by the straps. This allows the contracting muscle to pull the working finger toward the position held by the others instead of away from it and gives an easier movement.

This instrument fulfills the requirement (1) that the muscle works only when pulling the weight upward; (2) that the tension varies; (3) that the inertia be reduced and (4) that the muscle be neither loaded nor after-loaded. But the mechanical construction is at fault since the heavy weight after being raised to a distance of 50 cm. must be lowered again before the work can be continued again, thus allowing a rest for the muscle. Therefore, while it is suitable for ordinary fatigue work, it is not adapted to recording continuous efforts. That the experiments might continue with the same idea in view, another instrument of different mechanical construction, but involving the same principles, was made and substituted. Its construction and methods of work will be given.

THE AIR CUSHION.

The essentials of this instrument consist in an upright cylinder (see Fig. 2, *c*) closed at the lower end except for a large inlet valve (*a*) and at the upper end by a very thin sheet of dentist's rubber dam loosely stretched across it. A stopcock (*b*) is placed in one side of the cylinder. The weight while resting on the rubber sheet is not supported by it, but by a small metal bar (*d*) which strikes the frame. The action is as follows: As the weight is lifted from the cushion, air rushes in through the valve (*a*). When it is lowered, it strikes the rubber sheet and causes an increase of pressure within. This compressed air acts as a support until its slow escape through the stopcock (*b*) allows a return of the normal pressure within and the weight to be lowered, until it is caught by the metal bar. The rapidity with which it is lowered is regulated by the size of the opening made by turning the stopcock.

A wire extends from the weight up to an elbow lever (*l*) fixed at the end of the arm rest, and another extends horizontally from this to the finger where it is attached by an adjustable metal splint or boot (*sp*). The tracing lever records the actual movement of the finger on the drum (*D*). The size of the weight is easily changed by varying the length of the two arms of the elbow lever. The arm rest used was similar to the one described with the work-adder.

A PACE FOR THE WORKING MUSCLE.

In previous ergographic work much attention has been paid to the character of the individual tracing and to the production of fatigue. In general, not over one hundred contractions were necessary to bring on this fatigue. But very little study has been made to ascertain under what conditions a muscle can continue to work for a long period of time. In 1890, Maggiora[2] found that he could contract the middle finger of his left hand continuously at the rate of one contraction in two seconds against a weight of 1 kg. He concluded from his experiments that there exists for the human muscle a definite weight with which one can perform the greatest possible work. When the weight or the rate of contraction is increased, fatigue will occur. He also found that this maximum of work varies with different persons at the same time and the same muscle at different times. Lombard[3] contracted the abductor indicis muscle about 9,000 times, or for two and one-half hours, at the rate of once a second against a weight of 500 gms., reaching about the same conclusions as Maggiora. Both of these investigators used the weight ergograph which loaded the muscle and did not allow the muscle to work to the greatest advantage. Maggiora flexed the entire finger while the hand was in the supine position. Neither seems to have tried to compute the amount of work done by these muscles.

Fick[17] found that, using a heavy weight, about one-fourth of the total energy expended by a muscle is used in lifting it and the remainder is changed into heat, electricity, etc.; while with a light weight, only about

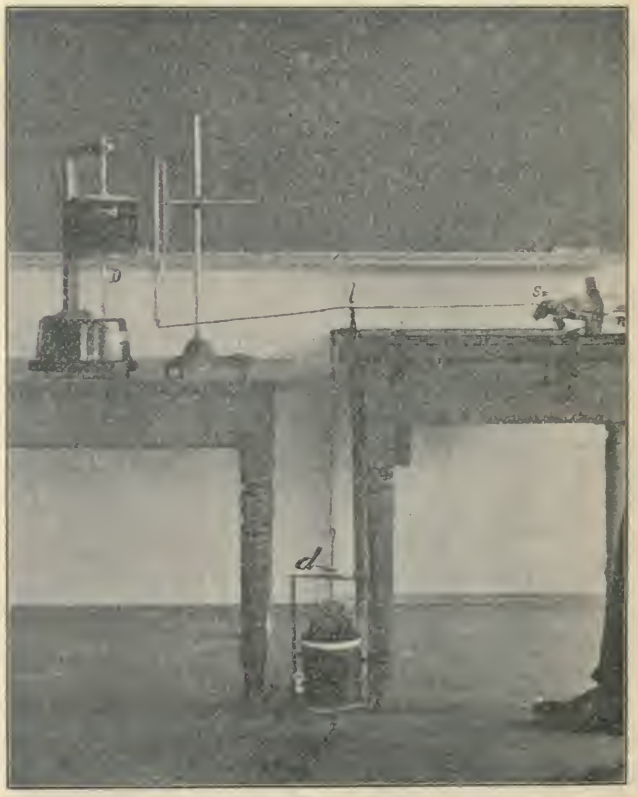

Fig. 2.—Ergograph with air-cushion. C, cylinder, about 10 cm. in diameter, having a large valve (a) opening from below; b, stopcock through which the air escapes on descent of the weight, the rate at which it escapes is regulated by the stopcock; d, metal bar soldered to the weight rod, this bar strikes the cylinder frame and serves to support the weight between contractions; l, elbow lever, so constructed that the two arms may be varied in length by hooking the weight cord or the power cord into different holes; Sp, finger splint; R, arm rest; D, drum of kymograph.

one-twentieth is spent as external work. That there is so much loss of energy is due, I think, to the fact that the muscle does not work to the greatest advantage. While some attempts have been made to improve the condition under which the muscle works, sufficient data have not been tabulated to show the true value of these changes.

The results given here were obtained principally on the air cushion. That the muscle might be in training, as Hough[18] has shown is necessary for the best results,

17. Fick: Pfluger's Archives, 1878, xvi, p. 85.
18. Hough: Ergographic Studies in Muscular Soreness, Amer. Jour. of Physiol., 1902, vii, p. 76.

the experiments were continued over a period of two months in the spring of 1902 and about three months in the spring of 1903. Tracings were made at least every other day. While the experiment was being made, the subject sat at a table with the right arm and hand fastened in a prone position to the rest. Different weights were used, the rule being to increase them as the finger becomes accustomed to the work. At first the muscle became tired very quickly, but after a few weeks it gained in power and could use the heavier weights at a faster rate of contraction. The rhythm was usually a matter of choice and was influenced largely by the object in view. While many found that they could bring on fatigue within one-hundred contractions at the rate of one contraction every two seconds, I found that I could go at a much faster rate and continue a very much longer time without fatigue necessarily following. The height of the contractions remained practically the same, varying from 1 cm. to 1.5 cm. in height. Throughout the experiments care was taken to keep the nutrition of the finger and muscle as nearly normal as possible. No attempt was made to compute the friction, which was comparatively small. Tension on the muscle was present only during the lifting of the weight.

The following table shows some of the results obtained:

TABLE 1.

Date.	Time of Day.	Duration of Experiment, hrs.-min.	Weight in Kilograms.	Contractions per Second.	Average Height of Contract's in cm.	Number of Contractions.	Kilogram-meters of Work Done.
A.—Results Obtained on the Work-adder in Spring of 1902.

* No fatigue. † Some irregularity. ‡Tracing irregular after 9 minutes; fatigue in 42 minutes.

Part A of Table 1 shows the results of the experiments on the work-adder. The longest single experiment was made May 8, and lasted for a period of three hours and forty-seven minutes, during which time over 11,000 contractions were made, and about 625 kilogram-meters of work accomplished. May 10 two tests were made with an interval of one hour and thirty minutes. The work done that day amounted to over 1,000 kilogram-meters. No fatigue other than a general body weariness was experienced after these experiments, and the height of the contraction remained very constant throughout each experiment. But the experiments were not above criticism, as there was some movement of the whole finger, and intervals of rest were made necessary when the weight was lowered.

Part B of Table 1 shows the work accomplished on the air cushion. March 28 I made 12,600 contractions in three and one-half hours. The rate was one contraction every second against a weight of two and one-half kgs. The average height of each of the tracings was 1.1 cm. and the total work accomplished 346.5 kilogram-meters. No fatigue occurred. On April 1, the rate of contractions was changed to 2 per second and the weight to 3 1/3 kgs. It was thought that this would bring fatigue; but to my surprise, after some irregularity in the tracing, the height of the contractions became more even and no fatigue was produced in two and one-half hours. The next tracing was made at the rate of two contractions a second with a 5-kg. weight. The tracing was regular for nine minutes, then varied considerably in height until fatigue (a failure to move the weight) came on at the end of forty-two minutes.

On April 4 the weight was changed back to 3 1/3 kgs., and with the same rate 26,400 contractions were made in three hours and forty minutes. The contractions varied between 1 and 1.4 cm., with an average of about 1.1 cm. Not over twenty-five strokes were lost during the entire time, and the wide variations to be expected from weariness or disturbances were surprisingly absent. No fatigue occurred except a general weariness of the whole body, which lasted during the remainder of the day. The weariness did not stop the work of the experiment, however. The total amount of work was over 968 kilogram-meters.

Comparing this last tracing with that of April 2, it will be seen that the heaviest weight that this muscle can lift continuously, contracting twice a second, is between 3 1/3 and 5 kgs. No similar amount of work has, to my knowledge, been recorded previously by a single muscle. This apparent increase of ability must be due, in a great measure, to the more advantageous conditions under which the muscle is working. Just how long this work could have continued I will not venture to say definitely, but the fact that I could keep up this pace for three hours and forty minutes without fatigue of the muscle following would justify the conclusion that the muscle could have done more. It is evident in the above experiment that the muscle had sufficient rest after each contraction to recover from the effects of that contraction. Had this not been the case fatigue would have been the result, as it had been with the use of the 5-kg. weight.

Since so many factors enter in to modify the conditions, it is not to be expected that the results will be the same in each experiment; but with the conditions sufficiently favorable it may be concluded that a muscle is able to do a day's work of eight or ten hours' duration.

FATIGUE.

Mosso,[1] Lombard,[3] Maggiora[2] and others found that the muscle became tired and could not lift a given weight after from 50 to 100 contractions, the rate being once a second. With them, the amount of work, as well as the extent of movement, decreased as fatigue was approached. Franz[19] found that with the spring he could contract 150 times and still do about 40 per cent. as much work as at the beginning of the series. During the present experiments the muscle was fatigued several times and it always gave results far in excess of those obtained by these men. The muscle did not become fatigued within a period of three hours and forty minutes when it raised a 3 1/3-kg. weight twice a second. On April 2 the muscle became fatigued in forty-two minutes after having made over 5,000 contractions against a 5-kg. weight, lifting it twice a second. After a lapse of about four weeks, it made nearly 4,000 contractions under the same conditions.

That I might find a cause for this great difference in ability, I made a few experiments with the Mosso form of ergograph. Table 2 shows some of the results as compared with those taken with the air cushion:

19. C. f., p. 368

TABLE 2.

Date. 1903.	Length of Contraction in Minutes.	Weight Used.	Contractions per Second.	Number of Contractions to Fatigue.	Results.
RESULTS WITH AIR-CUSHION.					
April 2	42	5	2	5,040	fatigue
April 4	220	3 1/3	2	26,400	no fatigue
April 29	33	5	2	3,960	fatigue
RESULTS WITHOUT AIR-CUSHION.					
April 5	22	3 1/3	2	2,640	fatigue
April 16	24	3 1/3	2	2,880	fatigue
April 29	1:08	5	2	135	fatigue

These tracings compare the time and work necessary to produce fatigue when the air cushion is used and without it.

These results do not agree with those obtained by the previous investigators. With a weight of 3 1/3 kgs. twice a second, there was no fatigue until 2,640, and in another 2,880, contractions had been made. At another time the muscle, contracting every half second, raised a weight of 5 kgs. 135 times before fatigue was produced.

The question arises, why there should be such a difference in the amount of work necessary to produce fatigue? The individual variations of the muscles would easily explain small differences, but would not suffice here. The muscle that I used was below the average in strength before the experiments began, and the time over which the experiments extended would scarcely allow such great increase in power. The difference which exists between the tracings made with the air cushion and those with the Mosso form of ergograph can be explained to a great extent by the conditions under which the muscle was working. The other is evidently the result of the endurance which the muscle gained by working many times over an extended period.

RECOVERY AFTER FATIGUE.

It was also noticed that the periods of recovery after fatigue had been reached were very much longer when the air cushion was used, than when the Mosso form of ergograph was used. The average number of contractions in the recoveries of an experiment lasting one hour and forty minutes was eighty-five, and the average intervals of absolute fatigue was fifty seconds, varying in length from 2 to 10 cm. The weight used was 5 kgs., raised every one-half second. There was no regularity in the length of the recoveries, while the intervals of loss of power had a tendency to become longer as the experiment was continued. For a detailed discussion of this subject the reader is referred to the work of Lombard.[20]

SUMMARY.

1. A muscle working under normal physiologic conditions is neither "loaded" nor "after-loaded."

2. A muscle will not contract isotonically nor isometrically under normal physiologic conditions.

3. When a Mosso or a spring ergograph is used, a large part of the energy expended by a muscle during a period of work is lost. This loss occurs in easing back the weight or the spring to its position of rest or to the zero point.

4. A recognition of the conditions under which a muscle works and the end to be attained is necessary when an interpretation of ergographic results is to be made.

5. A normal muscular contraction ("normotonic") consists in contraction, relaxation without load, rest.

6. A new form of weight ergograph has been devised which allows the human muscle to work at a greater advantage than that given by any previous form of ergograph, because it permits "normotonic" contractions.

7. A human muscle is capable of doing a far greater amount of work by the use of the new ergograph than has been previously shown in ergographic work.

8. A muscle can work over periods of long duration without fatigue when the conditions are favorable.

9. These experiments confirm the conclusion stated by Maggiora that there is a definite weight with which one can perform the greatest possible work.

10. The physiologic limit of a muscle for continuous work is modified by the rate, load and interval, or by rest and work.

DYSTOCIA CAUSED BY DOUBLE CONGENITAL CYSTIC KIDNEYS IN THE NEW-BORN:

A CONTRIBUTION TO THE STUDY OF CONGENITAL CYSTIC KIDNEY.

EDWARD E. MORSE, M.D., L.M. (DUBLIN).

Demonstrator of Obstetrics, Columbian University; Associate Visiting Surgeon Columbian Hospital for Women; Associate Obstetrician University Hospital.

WASHINGTON, D. C.

Spiegelberg, in his well-known "Midwifery," vol. ii, p. 169, speaking of the causes of difficult labor produced by anomalies of the fetus and appendages, says: "The various causes which lead to the enlargement of the abdomen of the fetus are the following:

"1. An accumulation of serum.

"2. The distention of the urinary organs with urine, both bladder and uretus.

"3. Cystic degeneration of the kidneys.

"4. Distention of the uterus with fluid.

"5. Tumors of the liver, spleen, testicle in the abdomen.

"6. Aneurism of the aorta.

"7. A condition in which one fetus is included in another."

Under the third of these headings, viz., cystic degeneration of the kidneys, I wish to report a case of dystocia which recently occurred in my practice:

Mrs. X., aged 20, primipara, healthy, and pelvis normal, came into labor early in the morning of January 19. In the beginning the pains were of normal character and continued increasing in strength and frequency during the day and evening. Dilatation of the os was very slow. A breech presentation was easily diagnosed. The pain steadily increasing and becoming progressively harder and the os not opening proportionately, it was decided at 11 p. m. to anesthetize and deliver. Under ether there was no difficulty in dilating sufficiently to admit several fingers and grasp the feet. Traction brought the limbs well through the os, but the abdomen resisted all efforts. An examination cautiously made demonstrated some obstruction of a very considerable character in the abdomen, which was felt to be enormously swollen. By repeated and persistent traction, combined with careful manipulation, the trunk and after-coming head were eventually born, without resorting to any cutting or destructive operation. When born the child breathed a few times, not, however, emitting any cry, but very shortly breathing ceased.

The uterus contracted firmly after the discharge of a small quantity of blood, very dark in appearance. The recovery of the mother was uneventful. The conditions surrounding

the case were of such a nature as to forbid a careful post-mortem examination. Permission, however, was granted to open the abdomen and learn something of the true condition.

The child, male, must have been very near full term, although it was claimed that it was only eight months. No deformity was visible in limbs or parts, beyond the unusually large fontanelles both anterior and posterior, these being far larger than is usually found in the new-born. It is worthy of note that the head in conditions similar to this so frequently hydrocephalic, was not in this instance abnormal. The attention was at once fixed on the abdomen, which was very prominent and greatly distended. I regret that lack of time and material forbade the exact measurements. In appearance, however, it was not unlike that frequently seen in malignant disease when ascites has caused an extreme distention of the abdominal walls. Palpation and percussion showed the presence within of a solid body or bodies, as the parts could be readily felt by the tips of the examining fingers, and percussion emitted the dull note of solid bodies. An incision was made through the abdominal walls in the median line. Only a small quantity of fluid escaped. Inserting the hand in the line of the incision a solid mass was found to occupy the entire abdominal cavity, completely filling the pelvis and pushing

Fig. 1.—(×100.) a, Efferent vessel? b, Atrophied glomerulus. c, Cystic capsule of Bowman. d, Area of hemorrhage surrounding engorged vessels.

the liver and diaphragm high up in the thorax. Lying on the surface of the mass were the flat, ribbon-like intestines. Careful inspection showed that the mass was in reality two distinct bodies, both uniform in shape and consistency, meeting in the median line, forming a fissure. By exploration with the tips of the fingers it was found that the two tumors in question were in reality the two kidneys, far advanced in a state of cystic degeneration. The left was removed and is the specimen from which the accompanying microscopic slide was taken (Fig. 1). Very little of the original kidney structure remained. Stripping away the capsule the entire kidney—fully eight inches in length and four in width—was found to be filled with cysts, varying in size from a small pea to a good-sized marble. These cysts were filled with fluid, clear and serous in character. The ureters were found and a probe inserted proved them patulous for about three inches. Little or no examination could be made of the remaining viscera beyond the fact above mentioned, of the great upward displacement by compression of the liver, lungs, heart, etc. The kidney was submitted to Dr. James Carroll, assistant curator of the U. S. Army Medical Museum, who made a careful microscopic examination, the report of which is here quoted:

"The section resembles one of an adenocystoma or of the multilocular cystic degeneration that is seen occasionally in the ovary. The stroma consists of a loose fibrous reticulum fairly rich in cells. These cells are, as a rule, slender spindles with oval nuclei; in the looser portions there are some multipolar and round cells with oval or spherical nuclei. There is marked infiltration of the stroma with red blood cells and here and there small and large hemorrhages. The vessels, as a rule, are small and engorged with blood. The cystic spaces are lined with a compact layer of stratified round epithelium and are surrounded by a dense wall of cellular connective tissue. In some instances this wall is of considerable thickness and very rich in cells. The surrounding stroma shows here and there small isolated groups of contorted tubular structures resembling glandular acini. They are not surrounded by capsules and their walls appear to consist of cuboidal epithelium. The lumina of the tubules are seen in cross section to be packed with similar cells whose nuclei stain rather poorly. These acinus-like bodies are at times surrounded by small hemorrhages, again by a number of polymorphonuclear leucocytes. The grouped arrangement of these structures and the character of the cells within them would lead one to suppose that they were uriniferous tubules, but on comparison with undoubted tufts within both the distended and non-distended Bowman's capsules it is clear that they are the remains of malpighian bodies whose capsules have merged with the surrounding fibrous tissue and disappeared. In other places the malpighian bodies appear to have undergone a different change; within some of the above described cystic spaces the remains of a tuft can be seen projecting from the thickened wall into the lumen. These tufts are covered by round or cuboidal epithelial cells similar to those lining the sac. The character of the epithelium is the same when the tufts and capsules are of approximately normal size as when the capsules have been distended to form cysts.

"The uriniferous tubules have almost entirely disappeared. One or two may be seen of considerable length, slightly enlarged and filled with low cuboidal or round epithelial cells. Their basement membranes have undergone enormous proliferated thickening, are very rich in cells and closely resemble the thickened capsules of Bowman already described.

"On the whole the general changes appear to be atrophy of the epithelial structures; marked connective tissue increase; hemorrhages and cystic dilatation of a number of the periglomerular capsules of Bowman. The cystic contents appear as an almost indistinguishable structureless material showing that the fluid contained but little albumin."

Cases of congenital cystic degeneration of the kidney have been reported at intervals. The affection, while definite in character, remains, however, among the rarer diseases of the renal bodies. It is especially rare as a cause of dystocia. In a few of the cases on record the enormous distention of the kidneys necessitated puncture of the abdominal walls and practical evisceration before delivery could be effected. Fussell[1] spoke of 11 cases in which the kidney obstruction was so great as to render mutilation imperative. In his case the abdomen measured 18 inches at the umbilicus, both kidneys enormously enlarged, the left 6x5 inches, the right 5x4 inches, both in original form, lobulated and the seat of cystic degeneration, the mass composed of a multitude of small cysts varying in size from a pea to a pin point. The suprarenal capsules were enlarged. The heart was much hypertrophied and about three times the normal size; ventricles small; walls of left ventricle 5/8 inch thick, right 3/8 inch; valves normal.

Frequently associated with congenital cystic kidney in the new-born are defects of development, hydrocephalus, cleft palate, hare-lip, spina bifida, anomalies and defects of the genito-urinary organs. Duffey[2] reports a case of

1. Medical News, January 10, 1891.
2. Medical Times and Gazette, London, Feb. 10, 1866.

this disease in which the fetus was of anencephalous variety, the uterus bifid. This co-association of cystic degeneration of the kidneys and anomalies of development has led to the theory, of which we will speak later, that the disease is one of defective development rather than a change brought about by pressure or inflammation, or both.

The etiology and pathology of this interesting condition still remain largely *sub judice*. Beginning with Virchow in the early 40's, who explained the formation of cysts as the result of uric acid infarcts—an opinion now abandoned—down to the present day, theories have not been wanting. Whether congenital cystic kidney is due to defective development (embryonic theory), to pressure and obstruction (mechanical theory), or pathologic changes of a more complicated nature (the inflammation theory) are questions which have never been satisfactorily answered. Regarding these three theories of causation, somewhere within which, in all probability, the truth lies, Hektoen, writing on the subject in a very exhaustive article,[3] says:

1. The theory of retention and dilatation is based on cases in the new-born and old in which were demonstrated causes of obstruction at uriniferous tubules, papillæ, etc., including fibrinous casts, degenerated epithelium blood, precipitated salts. Virchow assumes a papillary atresia or stenosis due to fetal inflammation.

2. The theory of a cysto-adenomatous growth is based on the presence in cystic kidney of adenomata.

3. The embryonic or developmental theory which seems to explain many features otherwise unintelligible is based largely on the fact, so apparent in the majority of cases, of general abnormalities of development, as quoted in cases cited above. This idea, so clearly advocated by Shattuck and Bland-Sutton, is in brief essentially this, that the wolfian bodies and the kidneys, which in normal circumstances are distinct become blended, and through this failure of differentiation an abnormal kidney results with cystic formation as an accompaniment. This view is the one adopted by Osler and incorporated by him in his article on congenital kidney in the latest edition of his "Practice of Medicine." Rindfleisch ascribes the condition to a congenital atresia of the renal artery. Neuwerck, Hufschmid and Von Kahlen incline to the idea of adenocystoma. Fürbringer has the following: Congenital cystic degeneration (Virchow's *hydrops renalio cysticus congenitus*) is usually bilateral. According to researches its origin is generally to be found in the coalescence of the tubuli uriniferi, in obliteration of papillæ by embryonic nephritis, and in the production of uric acid infarcts. The obstruction may also be found in the urinary tract, as the condition may result from the atresia of the pelvis. Klebs assumes external mechanical influences, and Niebending attributes it to engorgement of the kidneys produced by the absence of the ductus Bottali.

It is obvious that the diagnosis of congenital cystic kidney can not be made early enough to be of any practical value to the obstetrician. Its occasional occurrence, however, should not be overlooked in those cases in which there is prolonged and unnatural resistance to the birth of the body. Careful examination demonstrating the abnormally distended condition and all other efforts failing to effect delivery, the physician is justified in puncturing the abdominal walls, passing his fingers through the opening and by the removal of the enlarged kidneys reducing the size of the child sufficiently to admit of its passage through the birth canal.

It not infrequently happens that cases of cystic kidney fail to go to term. Should, however, such a pregnancy survive to the full period of gestation, the child is still-born or expires within a few minutes after birth. The causes of death are numerous. Asphyxia from compression of the lungs and diaphragm is the direct cause in a great majority of cases, particularly those in which there is great abdominal swelling, anuria, symptoms of anasarca, coma convulsions; tetanus and other uremic symptoms appear sooner or later, and death very rapidly supervenes.

Clinical Reports.

AN EIGHTY-EIGHT POUND OVARIAN CYST SUCCESSFULLY REMOVED FROM A PATIENT SEVENTY-SEVEN YEARS OF AGE.

BENJAMIN R. SCHENCK, M.D.
Formerly Resident Gynecologist, the Johns Hopkins Hospital, and Instructor in Gynecology, the Johns Hopkins University.
DETROIT.

In these days of operative activity, ovarian tumors weighing more than fifty pounds are sufficiently uncommon to attract attention. The mortality of the operation being so small, and the zeal of the surgeons so great, we no longer see the enormous cysts, which in the earlier days were comparatively frequent.

There being several minor points in the following case, both in the physical signs and in the after-treatment, I feel justified in reporting it in full.

History.—Mrs. M. S. entered Johns Hopkins Hospital March 23, 1903. She was barely able to stand or walk alone on account of a large abdominal tumor, and the infirmity of her age, which was asserted by her companion to be 77 years. She was of Irish descent, illiterate, and had lived for many years in the slums of Baltimore.

Present Trouble.—As far as could be ascertained, for six years the abdomen had gradually increased in size, and for the past six months she had been in bed. She had suffered little real pain, but had complained of great respiratory distress and oppression on the slightest exertion. At times there had been considerable swelling of the ankles, but no urinary disturbance had been noticed. The appetite had been fairly good, and the bowels habitually constipated.

Examination.—She was much emaciated, the face deeply wrinkled, but presenting no suggestion of the ovarian facies; the skin over the whole body was deeply pigmented and brawny. The percussion note over the lungs was resonant, and the breath sounds were harsh, with râles at the end of expiration, which was everywhere prolonged and blowing. The heart sounds were sharp and clear. The temporal, facial, radial and tibial arteries were tortuous and much thickened, standing out as hard cords. Pulse, 80 to the minute, intermitting frequently and obliterated with difficulty, the pressure necessary being 175 mm. of mercury. The lower ribs, pushed upward

by the enormously distended abdomen, formed an angle of nearly 45 degrees with the upper ribs. In dorsal decubitus the abdominal distention began at the sixth rib, rising gradually and forming a dome-shaped tumor, overhanging the symphysis. This tumor was tense on palpation, and presented a perfect percussion wave. The percussion note was flat, except high up on both sides, where there was modified tympany. On turning the patient from side to side, there was a suggestion of tympany, but no distinct movable dullness could be demonstrated. The circumference at the umbilicus measured 134 cm. (53 inches). The vaginal outlet was much relaxed and the bladder prolapsed. On account of the greatly distended and tense abdomen, a bimanual examination was impossible. The urine was dark yellow, cloudy, acid in reaction, and of a specific gravity of 1028. A trace of albumin was present, and the microscope revealed bacteria in large numbers, epithelial cells, phosphates and urates, but no casts. The hemoglobin, estimated with the von Fleischel instrument, was 55 per cent.

Operation.—As the patient seemed a poor subject for general anesthesia, March 25 I made a short median incision under cocain. This revealed a very thin cyst wall, purple in color, and quite firmly adherent to the parietal peritoneum over its anterior surface. The cyst was punctured and 38 liters of dark brown fluid evacuated. The cyst was practically uni-

locular, and was therefore readily and completely emptied. Attempted separation of the adhesions between the cyst wall and the parietal peritoneum was so painful that nitrous oxid gas was administered, and the two layers rapidly separated by wiping with a gauze sponge; here and there more dense adhesions, requiring the use of scissors or knife. The omentum, which was adherent to the cyst, was quickly tied off, and the latter delivered. Fortunately, there were no pelvic adhesions, and the very broad pedicle was readily clamped off, the tumor removed and the vessels ligated with silk and catgut. After covering in the stump, the abdomen was rapidly closed with through-and-through silkworm gut. A very small amount of ether was given, although the operation could have as well been concluded under nitrous oxid anesthesia alone. The patient was conscious before the last abdominal suture was tied.

Examination of the Tumor.—Investigation in the pathologic laboratory revealed a simple cystoma ovarii, lined by one layer of high columnar epithelium. The tumor and contents weighed 88 pounds.

Convalescence.—The lung condition seemed to be the greatest danger threatening the convalescence, as hypostatic congestion was greatly to be feared. With the hope of avoiding this the position of the patient was changed every two hours during the first forty-eight hours by alternately raising and lowering the head of the bed. Despite an extremely irregular and intermittent pulse, the convalescence was uninterrupted, and healing was perfect in every particular.

Comments.—The interesting points in the case are the age of the patient, the development of a large tumor from an organ long past physiologic activity, the ease with which the operation was done with but little general anesthetic, and the speedy convalescence, despite diseased arteries and an unfavorable condition of the lungs. Attention is especially called to the possibility of preventing serious pulmonary complications, by a frequent change in position. This is not a new procedure, but it has not been extensively employed, and seems worthy of emphasis. To be effective, one end of the bed should be elevated by chairs placed under the bedposts, the patient being supported from slipping by shoulder and perineal straps. The head should be alternately raised and lowered in this way every two hours. In aged patients, with poor circulation and edematous lungs, this method of preventing hypostatic congestion and subsequent pneumonia, would seem of value.

FATAL BROMOFORM POISONING.

E. H. DWELLE, M.D.
NORTHWOOD, IOWA.

The facts of the following case were obtained by courtesy of the attending physician, Dr. C. A. Hurd.

Previous Illness.—A girl of 2 years and 9 months had been sick for about two weeks with whooping cough, with severe coughing and vomiting spells at frequent intervals day and night. Blood was vomited at times.

Treatment.—Belladonna and antipyrin had been given without much effect on the spasms. On the evening of July 21 the child was put on two-drop doses of bromoform every four hours with decided benefit, the patient sleeping comparatively undisturbed that night; the next day she was playing about the house and yard, with only an occasional attack.

Poisoning.—About 7 p. m. of the 22d the child went to a drawer, took out the bottle of bromoform and swallowed some of the contents. The burning sensation caused the child to scream, which attracted the attention of the mother, and she at once took the bottle away from the child. Some of the liquid had been spilled on the floor and on the child's dress. About half the contents of the 3-dram bottle remained.

Symptoms.—For several minutes the child seemed to be unaffected, but the mother attempted to telephone to town, about three miles distant, for a physician, and the telephone failing to work she called the child's father. By that time the child began to show signs of drowsiness. As soon as a team could be made ready they drove to town with the child, who was then apparently lifeless or in a condition of deep narcosis. They reached Dr. Hurd's Hospital about 8:30 p. m. No pulsation could be detected at the wrist or carotids and no sound of heart action was at any time to be detected.

Treatment.—Strychnia and whisky were injected hypodermically, the stomach washed out, the head lowered and artificial respiration begun. The only encouraging symptoms were occasional spasmodic gasping attempts to breathe. The breath smelled strongly of bromoform. The pupils were widely dilated. There was no cyanosis until after about three hours, when the body began to get cold and the lips and fingernails blue. It was not until then that artificial respiration was abandoned.

Dose.—The amount taken can only be estimated. Of the three drams prescribed 10 or 12 drops had previously been taken. About 1½ drams remained in the bottle, and an uncertain amount had been spilled, but by conservative estimate 30 or 40 minims was the maximum amount swallowed.

Comments.—No very accurate conclusions can be drawn from this case, except that bromoform is a dangerous drug, probably more poisonous than chloroform, and should be handled with care. Its action was comparatively rapid and apparently paralyzed the heart's action and vasomotor system more rapidly and completely than it did respiration. It was effective in controlling the spasms of whooping cough, when used in full doses, but its agreeable taste makes it a temptation to the child who has access to it.

New Instrument.

A NEW AIR-DILATING URETHROSCOPE.

ERNEST G. MARK, M.D.
KANSAS CITY, MO.

For some time past I have been an advocate of the more general use of the endoscope in the treatment of chronic urethritis and urethral lesions. While my work with the various instruments designed for endoscopy has given me good results, I have at the same time felt the need of improved technic in this work. The advent of the mignon lamp of Koch of Rochester was a distinct advance over the platinum loop of the Oberlænder instrument and the various forms of reflected-light instruments. The application of the air-dilating principle of Schall and Fenwick, while an advantage, was more than offset by the disadvantages of the means of illumination.

Realizing the advantages of air-dilatation applied to urethroscopy and of the cold lamps made in this country, I devised the instrument which is here illustrated, and which, I believe, combines the valuable features of former instruments, while being free from their disadvantages. The instrument has for its component parts an endoscopic tube having the points of excellence of the Guiteras tube; a universal head which is attachable to any size of endoscopic tube by a screw joint and which has the valve attachment for the dilating bulbs; a light-carrier having at its distal end a mignon lamp and fitting into the universal head by a bevel joint, insuring an air-tight connection; an obturator having a universal handle and a glass window fitting into the light-carrier by a bevel joint. The light-carrier is adjustable to any size of endoscopic tube by means of a screw connection between the light-carrier shaft and handle.

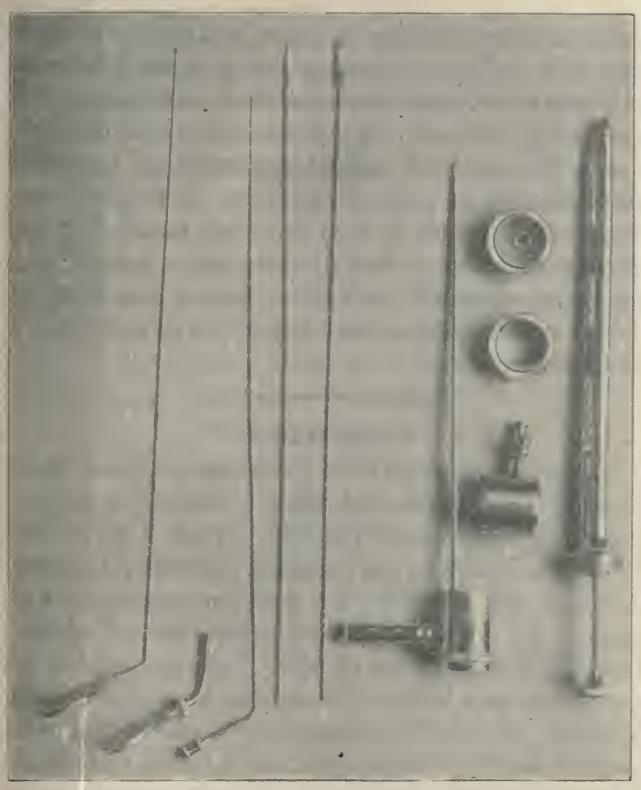

Fig. 1.—Aero-urethroscope. 1. Tube with obturator inserted. 2. Universal head with stop cock attachment. 3. Light-carrier. 4. Observation window. 5. Operating window. 6 and 7. Knives. 8. Handle for knives. 9. Canula. 10. Probe.

The possibilities of air-dilatation appealed to me so forcibly that I added to the instrument a glass operating window which has in its center a metal adjustable gland, fitted with a rubber gasket, insuring an air-tight contact between the operating instrument and the gasket and yet permitting of all necessary mobility on the part of the instrument in use. The set of operating instruments, so far, comprises two knives, a canula and a probe, and their uses are obvious.

The technic of endoscopy with this instrument is simple. The tube to be used is selected and the universal head is attached. The light-carrier is then placed in the universal head and so adjusted by the handle that the distal end of the light-carrier falls into the groove in the distal end of the tube. The obturator is then inserted, the connection made with the battery and the instrument introduced the required distance. Then the obturator is withdrawn and the excess secretion mopped up. The bevel window is inserted and, the dilating bulbs having been attached, the penis is grasped in the left hand while pressure on the bulbs with the right makes dilatation. The collapsed, stellate folds of the urethra are obliterated and the urethra comes into view as a tube, every point on the walls of which can be accurately observed. If the endoscope was properly selected and an excess of air pressure is not caused, no air escapes along the sides of the instrument.

On account of the extensive area brought under observation any lesions contrast strongly with the adjacent healthy mucosa. Cystic follicles form projecting points. Congestions or erosions are easily recognized in character and extent. Submucous infiltrations form irregularities in the lumen of the urethra.

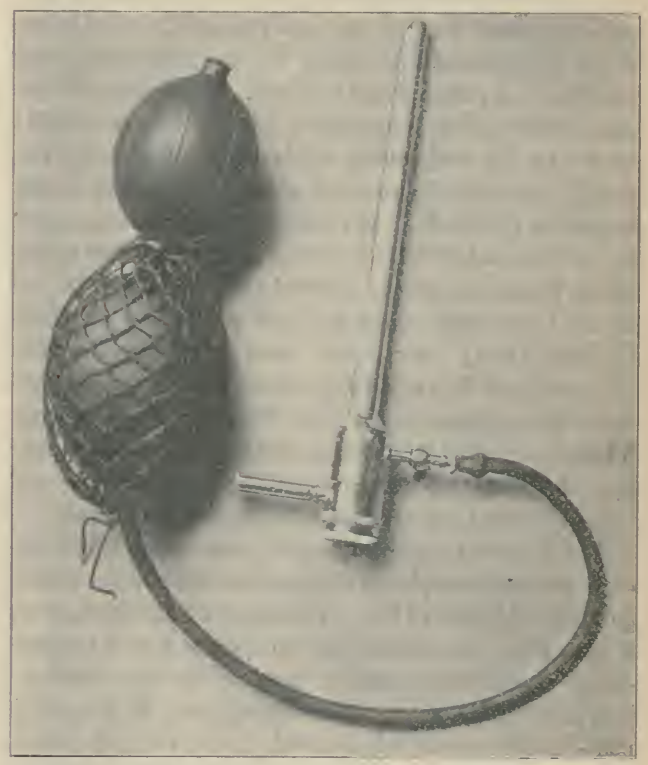

Fig. 2.—Aero-urethroscope, with universal head and light carrier in place. Obturator withdrawn and observation window and dilating bulbs attached.

In two locations, especially, I have found this instrument of unusual service, namely, the bulbous and prostatic portions of the canal. It is in these points of physiologic dilatability that urethroscopy with the ordinary urethroscope has proven unsatisfactory, the urethra falling into such folds as to conceal gross lesions despite skillful manipulation. Endoscopy of the prostatic urethra has proven particularly difficult on account of the wide dilatability of this region as compared with the narrow membranous portion. Naturally, an endoscope which would pass comfortably the membranous urethra would find the prostatic portion thrown into voluminous folds. On account of the rigidity imparted by the triangular ligament it is practically impossible by any manipulation to obliterate these folds. With this instrument the constriction of the compressor in front and the tonic spasm of the internal sphincter behind form an ideal location for air-dilatation, every point in the prostatic urethra falling into view. The bladder should be emptied before attempting posterior endoscopy.

SATURDAY, DECEMBER 19, 1903.

THE TYPHOID EPIDEMIC AT BUTLER, PA.

The calamitous outbreak of typhoid fever at Butler must be ranked not only as one of the most extensive epidemics of the kind that has ever occurred in this country, but as one of the most extensive on record anywhere. Several of the largest epidemics of recent times have occurred in England and the United States. The magnitude of the Maidstone (England) epidemic, perhaps, surpasses that of any other carefully studied typhoid epidemic of late years, about 1,900 cases being recorded in a population of 35,000. The celebrated epidemic at Worthing, England, in 1893, gave rise to 1,317 cases. In the well-known epidemic at Plymouth, Pa., in 1885—perhaps the severest of all in proportion to the population involved—1,104 cases developed among a population of about 8,000. The total number of cases occurring at Ithaca last spring reached approximately 900. At Butler, a city with about the same population as Ithaca (15,000-16,000) over 1,200 cases have already been registered, and it is said that new ones are being reported at the rate of 10 to 15 per day. The proportion of cases to population at Butler will doubtless be somewhat lower than at Plymouth, but the total number of cases will probably exceed any similar epidemic in this country.

It is certainly discouraging to have to chronicle another such catastrophe so close on the heels of the Ithaca epidemic of March, 1903. The mode of infection seems to have been the same in the two places, and a contaminated public water supply must again be accredited with the responsibility of the misfortune. So far as the previous prevalence of typhoid fever was concerned, Butler seems to have had less warning than Ithaca; otherwise the conditions preceding the outburst appear to have been dishearteningly similar. The train has long been laid. The familiar and critical situation of an unpoliced, unprotected watershed on which cases of typhoid fever have been allowed to develop unwatched and apparently without efficient control of any kind, has finally culminated in the present disaster.

In pessimistic moments one is tempted to conjecture how many other smoldering foci of typhoid exist in various parts of the country, only waiting for a series of untoward accidents to fan them into flame.

It is perhaps a legitimate inquiry as to just how many such catastrophes will be needed to implant a sense of responsibility in the minds of water-works officials and local boards of health. In some communities it is not a matter of great difficulty to recover large damages from corporate authorities for personal injuries due to broken sidewalks or defective highways. Sooner or later, we believe, a similar sensitiveness will be aroused concerning the liability of some responsible organization for the distribution of infected drinking water. In the light of our present knowledge of sanitary matters and modes of infection one is disposed to ask whether it is reasonable for those in charge of the public health of a community to allow themselves to be diverted by new systems of plumbing and garbage disposal away from the vitally important matters of water supply and milk supply. The usual vehicles of infection and methods of transfer of specific disease germs are now so clearly understood that public opinion will not content itself much longer with the explanation of an unpreventable accident. With two such terribly illuminating examples as Ithaca and Butler to light the way to reform, it is evident that the most intelligent opinion in future will hardly be satisfied with the vague statement that a typhoid epidemic is due to a fortuitous concourse of circumstances. The question of responsibility will soon become as conspicuous in the matter of typhoid epidemic as it is already fast becoming in railroad accidents. If civilized communities are unable to keep infectious material of disgusting origin out of their drinking water, it is a humiliating confession of impotence. Let us hope that the Butler epidemic will at least help to put an end to laxity and indifference.

CHOLESTERIN.

As cholesterin seems to be a constituent of most if not all cells, it may be assumed that it is of some importance, even though the quantity is generally small, yet to this time its real purpose has remained practically unknown. Although chemically a much more complex body, it resembles the fat in its physical properties and solubilities, and because of the relatively large amounts in the nervous tissue it is usually thought of in connection with lecithin. Chemically, cholesterin is one of the most inert of the body constituents, and it seems improbable that it plays any part in metabolic processes, for which reason there have been those who have been content to consider cholesterin as merely a by-product in cell metabolism, which was present in the cells in recognizable quantities, chiefly because its resistance to alteration made its removal slow. It is probably because of this resistance to chemical alteration that cholesterin is so frequently found in areas of slow cell-destruction, such as healing tubercles, atheromatous areas, inspissated pus, etc.

The importance of cholesterin, not being in its chemical properties, therefore, is possibly to be found in its physical properties, and there is accumulating good reason for believing that this is the case. We have learned that the penetrability of various sorts of cells differs for different substances, and on this probably de-

pends an important part of cell individuality in physiologic manifestations. Since cholesterin is, like the fats and waxes in general, resistant to permeation by most fluids, it will undoubtedly make much difference in the physical properties of a cell whether it has much or little cholesterin in its make-up. We may here recall the important observation of Overton that the anesthetics are solvents of fatty substances, including cholesterin and lecithin, leading to the suggestion that it is the solvent action that accounts for the anesthetic effect, the nervous tissues being richest of all tissues in lecithin and cholesterin. Another observation indicating the importance of cholesterin in a physical way refers to the red blood corpuscles, which are also particularly rich in cholesterin. It would seem that it is the cholesterin that is chiefly, if not solely, attacked by certain agents that produce hemolysis. The vegetable hemolytic poison, saponin, seems to produce its effects by action on the cholesterin, and therefore the presence of free cholesterin in a fluid containing corpuscles will protect them from hemolysis by saturating the poison and preventing its entering or combining with the corpuscles. This, it will be noted, is in full correspondence with the usual conception of the nature of the neutralization of toxin by antitoxin, the antitoxin being the particular substance of the cell with which the toxin combines. Other hemolytic poisons, but not all, have been found to be similarly affected by cholesterin. It is also suggested that ether, chloroform, and bile salts, which have long been known as laking agents, are all solvents of cholesterin. Probably, therefore, the cholesterin is an important factor in retaining the hemoglobin within the erythrocytes, and it is quite likely that in other cells it has a similar effect with regard to their constitutents, not to mention the possibility of its preventing the entrance of substances from outside the cells. If cholesterin does in this way modify exchange of substances between cells and plasma it must have a most important influence on cellular metabolism.

To the practicing physician the word cholesterin usually suggests gallstones, for in this form alone has any practical importance generally been assigned to this substance. The source of the cholesterin that forms the gallstones has been a matter of contention for many years. At first it was widely held that a chemical change in the bile, perhaps because of errors in diet, led to precipitation of the small quantity of cholesterin that it contains normally. Naunyn, however, supported the theory that the chief source of bile cholesterin was in the columnar epithelium lining the bile tracts rather than the liver cells, and that in chronic inflammation it was produced in excess until a deposition occurred on some foreign body, such as desquamated epithelial cells or mucus, and that after the concretion was once started further production of cholesterin was stimulated by the irritation of the stone itself. The development of the bacteriology of cholelithiasis has corroborated this view to the extent of indicating the importance of chronic inflammation rather than dietary considerations. Recent studies by Wakeman[1] in Herter's laboratory strengthen Naunyn's theory, for he found that sterile inflammation produced by injecting corrosive sublimate, phenol and ricin into the gall bladder resulted in the presence of several times the normal proportion of cholesterin in the cystic bile, probably derived from the degenerating epithelium of the mucosa. This being the case, we can understand readily the occurrence of gallstones in chronic cholecystitis, and their usual multiplicity is perhaps partly due to the establishment of a vicious circle, the irritation by one concretion leading to conditions favorable for the formation of others.

TUBERCULOUS AND NON-TUBERCULOUS DISEASES OF THE RESPIRATORY TRACT.

We are all familiar with the fact first pointed out by The Journal nearly four years ago (April 14, 1900), that the deaths from acute non-tuberculous pulmonary affections, especially pneumonia and influenza, have been growing more frequent of late years, if we can depend on the published statistics, while the deaths from tuberculous diseases have been decreasing. This last fact we impute to our improved methods of public hygiene, popular education as to the prevention of tuberculosis, fresh-air sanatoria, etc. The great increase in the mortality from the non-tuberculous diseases we find ourselves unable to explain.

Ascher[2] presents some statistical evidence on this question and suggests an interpretation of the evidence. After a warning against the use of statistics by any but experts, he points out certain facts obtained by a careful study of the mortality statistics of Prussia between the years 1875 and 1901, comparing the deaths from tuberculosis with those from the other diseases of the respiratory tract (bronchitis, catarrh of the lungs, inflammation of the lungs and pleura, etc.). The curves representing the deaths from these two classes of lung disease show graphically a decline in the deaths from tuberculosis, beginning in the year 1880, and an increase in the deaths from the other respiratory diseases, beginning in the very same year. The two curves cross in 1890, and from 1892 on the curve representing the non-tuberculous is always higher than the curve representing the tuberculous. Nor is this due simply to the diminution in the death rate of tuberculosis. There is an actual as well as a relative increase in the non-tuberculous diseases, as is shown by the fact that the combined death rates from these two classes were the same in 1901 as they were in 1875. During the first five years of the period in question, i. e., from 1875 to 1879, the mortality from both tuberculous and non-tuberculous diseases of the respiratory tract was 48.29 per 10,000 living; and during the last five years, 1897 to 1901, in spite of

1. Trans. Assn. Amer. Physic., 1903, vi, 162.
2. Berliner klinische Wochenschrift, Nov. 2, 1903.

the diminution in the deaths from tuberculosis, it was 48.03, almost exactly the same. Rahts, the statistician for the Imperial Health Office of Germany, finds that the same change has taken place in the rest of Germany, outside of Prussia, and also in England.

Ascher gives less credit to the modern crusade against tuberculosis than it is accustomed to receive. As the fall in the death rate from tuberculosis began in 1880, two years before Koch's discovery of the *Bacillus tuberculosis,* eight or nine years before Cornet's work and at least ten years before Flügge's, it is evident that modern methods of isolation, prophylaxis, sanatorium treatment, etc., can not be entirely responsible for it. The increase in national prosperity has undoubtedly something to do with it, leading as it does to improved conditions among the working classes and to lessened emigration, for emigration always raises the apparent death rate by removing a certain proportion of healthy young adults. There are, however, deeper causes than these. That the decline in mortality from tuberculous diseases of the lungs is intimately connected with the increase in mortality from the non-tuberculous, seems to be proved by these Prussian statistics, which show that while deaths from tuberculosis in middle life are decreasing, deaths in early childhood and old age from non-tuberculous diseases of the lungs are steadily increasing, and also that the acute diseases of the lungs are gradually replacing the chronic. This must not be regarded as a mere coincidence. The removal during early childhood of an increasing number of persons with "predisposed lungs," lessens the number of those who would contract tuberculosis during later life. Indeed, it is claimed by Rahts that in those regions where infant mortality is very high, the death rate from tuberculosis is comparatively low. (In the Chicago health reports, on the other hand, the increase of pneumonia is coincident with decreased infant mortality.) As for the increase in the deaths from acute inflammatory diseases of the lungs during old age, that probably has a direct relation to the diminution in the deaths from chronic tuberculosis, the persons with chronic tuberculosis succumbing finally to influenza or pneumonia. The increasingly acute character of lung diseases is shown also by the fact that fewer tuberculous patients reach the age of fifty.

It seems remarkable that in these days of scientific research and of great advance in public hygiene, we should be utterly unable to control or even to account for this enormous, unprecedented increase in acute non-tuberculous diseases of the lungs. Ascher accuses the medical world of approaching the problems of hygiene from one side only—from the point of view of the chemist and bacteriologist—forgetting that, just as internal medicine requires not only experimental pathology but clinical work, so public hygiene requires not only investigations in the laboratory but in sociology as well.

SPENCER AND POPULAR BIOLOGY.

The recent death of Herbert Spencer has recalled general attention especially to certain of his theories that were popular among the medical profession a generation ago. Between the time when he wrote his "Principles of Psychology" as a young man and revised the latest edition of his "Principles of Biology," Spencer's views as regards the significance of life had undergone a decided change. In discussing Spencerian principles it is the custom of many to accept his earlier immature view as representative of his opinions rather than his latest thinking. In his "Principles of Psychology" he said: "The chasm between the inorganic and the organic is being filled up; the microscope has traced down organisms to simpler and simpler forms until in the protogenes of Professor Haeckel there has been reached a type distinguishable from a fragment of albumin only by its finely granulated character." In a letter published in *Nature* (Oct. 20, 1898), Mr. Spencer said: "In my revised 'Principles of Biology' I have contended that the theory of a vital principle fails and that a physico-chemical theory of life also fails; the corollary being that in its ultimate nature life is incomprehensible."

Mr. Spencer had thus come to recognize the mystery of life and its insolubility, as have practically all the great scientists who have expressed their opinions on the subject during the last decade. While undoubtedly he was a great thinker, too much of his philosophy is brilliant theorizing rather than scientific thought that will endure. As a distinguished American zoologist said not long since, "Nature never acts according to the anticipations of the closest philosopher." The phrase Spencer so often quoted, "the survival of the fittest," became one of the shibboleths of biology, but our generation is much more interested in the origin of the fittest, which is the real biologic problem, rather than in its survival, since this is manifestly due to certain inborn qualities.

Some of his other expressions have ceased to have the significance they had. Ontogeny recapitulates philogeny is no longer considered to be a basic principle in biology. All living beings originate in a single cell, but to consider by that fact that they all begin at a point in development beyond which the single cell creatures have never gone, is utterly false to our present knowledge of biology. Between the single cell fertilized human ovum from which man is to develop and the ameba there is an immense distinction, not only in possibilities, but also in physiologic constitution, in chemical composition and even in the physical arrangement of the materials. It is patient observation, not brilliant theory, that brings us enduring advance in science.

HOME MANAGEMENT OF TUBERCULOSIS.

The second Phipps lecture, delivered by Dr. Osler, December 3, had for its subject "The Home in Its Relation to the Tuberculosis Problem." A fact not always appreciated in the present enthusiastic crusade against

tuberculosis is that 98 per cent. of the sufferers from this scourge can not receive the sanatorium treatment which is now so much to the front as the remedy *par excellence* for this disease. It is only in the home management that this large per cent. of sufferers can have any hope, and this hope depends on the family physician. It was a good idea on Dr. Osler's part to call attention to this fact, for it is in this particular direction that the principal victory over the disease must be won. Sanatoriums must have an educating effect and are undoubtedly of immense value to the few that are able to receive their direct benefits, but if we are to look for any great decrease of consumption it must be mainly due to the general practitioner in his management of the cases that come under his care. Dr. Osler accepts the view that nearly all of us are infected, and that in old age but few of us will be found free from some focus of the disease. He also refers to the unsatisfactory present status of the theories of the origin of the disorder, and does not feel authorized to accept the recently enunciated views of Behring and others as to the incorrectness of the hitherto prevalent theory of air infection. While it matters a great deal how tuberculosis is acquired, nevertheless if its acquirement is such a universal thing the principal task in the fight against the disease must be to strengthen resistance. It is encouraging to think that about nine-tenths of all those that are attacked at some time in their lives must recover to account for the statistics as we have them, but the other one-tenth should be reduced to a still lesser fraction at the earliest possible moment. Dr. Osler's remarks are timely in that they bring out certain circumstances that are not always duly estimated by the general public or even by the members of our profession.

TRITURATION IN LIQUID AIR.

A study of the vital properties of organized matter is a complex one, and whatever may lead to doing away with some of its embarrassments is a certain advance. We hold that the vital functions of cells depend on the specific physiologic and chemical arrangements and that the ordinary methods of biologic and chemical research destroy these more or less. Attention is called to this difficulty in a recent communication[1] to the British Association for the Advancement of Science by Prof. MacFadyen, who has sought out a suitable method for obtaining the cell plasma for experimental work, as far as possible unaffected by physical and chemical agencies which would disturb its vital qualities. The chief previous work which has sought to avoid these objections is that on the yeast plant by Buchner, who, by mechanical rupture of the cells and release of their content with preservation of its properties, obtained some valuable results. The desiderata are rapid disintegration and the avoidance of heat and other interfering elements. Buchner's method produced good results, but MacFadyen has sought to still further improve on it. The method he has employed has been by the use of trituration in liquid air, and the most striking results he has obtained are with the bacteria by this method. It is well known that the bacteria are not immediately devitalized by intense cold, but are put in a position which permits of their rapid and effective trituration, thus releasing their cell contents. He has found by employing this method that certain bacteria possess intracellular toxins which are not otherwise obtained. Among these may be enumerated the typhoid bacillus and pus organisms. Another peculiar fact that he has observed is that in regard to the photogenic bacteria which lose their power of giving out light after trituration notwithstanding the unaltered condition of the plasma, thus indicating that the light-producing power is a vital one in some way connected with their organized, intact condition and not dependent only on their chemical and physical constitution. The brain of an animal dying of rabies loses also its infective property by trituration in liquid air, which he thinks supports the idea of an organized virus in this disease. Some new aspects of immunity are obtained from the intercellular standpoint and the method throughout seems to be new and withal one of decided value. Some of MacFadyen's results have been already referred to,[2] and the future prospects of the method are certainly encouraging.

1. Nature, October 22.

THE DIPHTHERIA BACILLUS AS A CAUSE OF GANGRENE OF THE SKIN.

In 1902, Sailer[3] reported two cases of gangrenous stomatitis following typhoid fever, in which the bacillus of diphtheria was found in the gangrenous patches. One of his patients, a boy, aged fourteen years, died in spite of the administration of 12,000 units of antitoxin; the other patient, a girl, aged eight years, recovered after the use of antitoxin. The bacillus of diphtheria has been found by several other observers in cases of noma of the mouth, as well as of the vulva. It seems, however, that noma is not the only gangrenous affection that may follow infection with this bacillus. Bernard and Jacob[4] have recently reported the case of a soldier, aged twenty-five years, who presented two furuncles on his left thigh. In a few days these boils opened and discharged, but the wounds, instead of healing, became larger, spread and appeared gangrenous, so that the patient had to enter the hospital. On admission there were scars, ulcers and pustules of a gangrenous nature on the skin, from which the *Staphylococcus pyogenes aureus* and a streptococcus were obtained. There was no apparent explanation for the condition, as the man had always been well and presented no pathologic conditions on examination. The skin lesions spread and increased in number and, about twenty-five days later, a second bacteriologic examination was made and diphtheria bacilli were found, as well as the staphylococcus and the streptococcus previously described. No diphtheria bacilli were found in the mouth, the pharynx or the nasal fossæ, nor, so far as could be learned, had he been in contact with a patient suffering from diphtheria. The patient was given 30 c.c. of diphtheria antitoxic serum in three doses of 10 c.c. each, after which the lesions cicatrized very rapidly. Cases of gangrene of the skin have been reported as the result of a pure staphylococcus infection, as a result of an infection with a pure culture of the diphtheria

2. THE JOURNAL A. M. A., p. 1416.
3. Am. Jour. Med. Sci., January, 1902.
4. Arch. Méd. Exp. et d'Anat. Path., September, 1903.

bacillus, and as a result of a symbiosis of these two organisms. The authors have collected a number of cases belonging to each of these three classes. The diagnosis of such an etiologic factor in cutaneous gangrene can be made only after complete bacteriologic examination. The case reported in the paper mentioned, therefore, may serve as an illustration of the value of bacteriologic studies in similar cases. The case also shows that disseminated gangrene of the skin is not a single nosologic entity, but that one form, at least, may be due to an infection with the diphtheria bacillus.

Medical News.

CALIFORNIA.

Dysentery Epidemic.—Dysentery is said to be epidemic in Caspar, Mendocino County. Several deaths have occurred.

Italian Hospital to Open.—The Italian Hospital, San Francisco, will soon be ready to receive patients. It is located in the old Toland College building, which is being remodeled.

Personal.—Dr. Charles C. O'Donnell, San Francisco, accompanied by his niece, has started on a trip round the world.——Dr. William D. Dilworth, Oxnard, has sold his practice and will spend two years in special studies in New York and Europe.

New Society.—A new and exclusive scientific society, with a membership limited to 40, has been organized in Los Angeles, known as the "Clinical and Pathological Society." The following officers were elected: Dr. Andrew S. Lobingier, Los Angeles, president; Drs. Fitch C. E. Mattison, Pasadena, and Jay H. Utley, Los Angeles, vice-presidents; Dr. Frank D. Bullard, Los Angeles, secretary; Dr. John R. Haynes, Los Angeles, treasurer, and Drs. Ernest W. Fleming and Milbank Johnson, Los Angeles, executive committee.

ILLINOIS.

Lays Cornerstone.—With due ceremony Rev. D. L. Crowe laid the cornerstone of the new St. Francis Hospital, Kewanee, December 8.

Data Wanted on Epilepsy.—The State Board of Charities has sent a circular letter to each physician in the state asking for definite data regarding epilepsy in the state.

Octogenarian Honored.—On the occasion of his eightieth birthday anniversary, December 2, Dr. William J. Chenoweth, Decatur, received a greeting signed by all the medical men of the city congratulating him and bearing good wishes.

Personal.—Dr. Samuel C. Plummer, Chicago, surgeon-in-chief of the Rock Island system, has been made secretary of the association of surgeons of that road.——Dr. Thomas B. Knox, Quincy, has succeeded Dr. Le Roy P. Barstow as physician of the township.——Dr. John T. Spence, Camp Point, has been chosen physician of Adams County.

Contagious Diseases.—Canton reports 100 cases of typhoid fever and 10 deaths.——Scarlet fever and diphtheria are epidemic at Geneva, and the public schools have been closed. Since October 25 there have been 17 cases of diphtheria in Pekin.——An outbreak of smallpox is reported from Locust township, Christian County.——Prevalence of scarlet fever has caused the closure of Palmer schools.——Lakeside, Winnetka, Evanston and Glencoe are alarmed because of the presence of scarlet fever.——Scarlet fever is said to be raging near Bunker Hill. In one family three deaths have occurred.——After a strenuous battle for two months smallpox has been stamped out of Moline. Twenty-six cases in all were reported.——At Millersville, 22 cases of smallpox have been reported.——Springfield has 14 cases of diphtheria and 21 cases of scarlet fever.

Chicago.

A Successful Auction.—At the auction of boxes for the charity ball, of which St. Luke's Hospital is the beneficiary, $15,450 was realized.

Reynolds Reappointed.—The mayor has reappointed Dr. Arthur R. Reynolds commissioner of health, and by a unanimous vote, on December 14, the city council confirmed the appointment.

New Hospitals.—The management of St. Joseph's Orphan Asylum has had plans prepared for a three-story hospital on the northwest side, to cost $20,000.——The Hospital Sisters of St. Joseph, Montreal, will build on land acquired in Englewood, a hospital to be called Hotel Dieu, and to cost $80,000.

December Health.—Thus far in the month the public health, as measured by the death rate, has been satisfactory. The average December rate for the previous decade was 15.24 per 1,000; for the first twelve days of December, 1903, the rate has been 13.36 per 1,000, or 12.3 per cent. lower than the average.

Personal.—Drs. William Engelbach and G. W. C. Parker, retiring internes at the County Hospital, will continue their studies in Vienna.——Dr. Craig R. Snyder, a former interne at the hospital, intends to enter the medical department of the Army.——Dr. Joseph F. Biehn, as the result of a competitive examination, has been certified by the civil service commission as city bacteriologist and superintendent of the milk and food inspection bureau.

Prophecy Fulfilled.—The forecast of the Department of Health that there would, between Nov. 1, 1903, and May 31, 1904, be an excess of pneumonia deaths over deaths from consumption in the proportion of more than 60 per cent. of the former to less than 40 per cent. of the latter, is fully sustained by the figures for the first 42 days of the period. During these six weeks there have been 286 deaths reported from consumption and 506 from pneumonia—a proportion of 36.2 per cent. for consumption and 63.8 per cent. for pneumonia.

Antitoxin Reduces Diphtheria Mortality.—The Department of Health, in its latest bulletin, thus comments on the value of antitoxin in diphtheria:

> Since the introduction of antitoxin in the treatment and prevention of diphtheria its mortality rate has been reduced by nearly one-half—that is, from an annual average of 6.25 deaths in every 10,000 of the population in the seven years 1889-1895 to an annual average of 3.24 in the seven years 1896-1902 of antitoxin treatment. But this is not enough.
>
> The seven years' experience clearly proves that no child should—that no child ever did die of diphtheria when treated early enough with a sufficient quantity of good antitoxin. The pre-antitoxin mortality of diphtheria in Chicago was about 35 deaths in every 100 cases of the disease. In the many thousands of cases among the poor and destitute treated by the department inspectors under the most adverse conditions the rate for the whole number has been less than 7 deaths in the 100 cases. And there are many physicians in Chicago and elsewhere who have records of hundreds of cases with a rate of less than 2 deaths per 100.

INDIANA.

Medical Library for Southern Indiana.—At a meeting of the Vanderburgh County Medical Association, November 17, steps toward the founding of a public medical library in Evansville were taken.

Will Not Endorse Contract Services.—At the regular meeting of the Delaware County Medical Society, December 4, the society took decided action against the indorsement of the "Red Cross Medical Association," recently organized in this and other counties of the state, on the grounds that it was impracticable, unethical and a form of contract service.

Personal.—Dr. Joseph G. Rogers, superintendent of the Northern Indiana Hospital for the Insane, Logansport, has had his salary increased from $2,000 to $2,500.——Dr. J. Rudolph Yung has been appointed police surgeon of Terre Haute, vice Dr. Myron A. Boor, who has been made smallpox physician.——Dr. Arvill W. Bitting, Lafayette, who was injured in a railway accident at Indianapolis, has returned home recovered.——Dr. August Knoefel, New Albany, has been made county physician of Floyd County.

Epidemic Diphtheria.—Diphtheria has caused the schools at New Haven to be closed.——At Michigan City a parochial school has been closed on account of the prevalence of the disease; four deaths have occurred.——The disease is prevalent at Emison and Oaktown and is said to be raging in Spencer County.——School at District No. 3, Hutton, has been closed on account of the disease.——Colfax County schools are said to be in unsanitary condition and the State Board of Health has been asked to investigate.——At Tell City two deaths have occurred.——Elwood has several cases.

IOWA.

Smallpox at Arlington.—There are said to be 50 cases of smallpox at Arlington; the city has been thoroughly quarantined, and it is hoped that the disease will not spread.

Ante-Nuptial Health Certificates.—The Iowa Society for Suppression of Disease and Degeneracy has prepared a bill to be proposed, providing for a physician's certificate of examination before a marriage license can be issued.

Personal.—Dr. Charles H. Hoffman, Des Moines, is suffering from a severe infection of the right arm, the result of an

autopsy wound.——Dr. Emmett C. Chapman, Fort Madison, has been elected president of the Santa Fe Hospital Association.——Dr. Malcom N. McNaughton, Villisca, has sold his practice to Dr. F. S. Williams, of Chapman, Kan.

Stops Indiscriminate Sample Distribution.—The Fort Dodge council has passed an ordinance prohibiting "the distribution of any sample packages of patent medicines, pills or other free samples of any preparation whatever for medicinal purposes by way of advertisement, by leaving the same on the porches or doorsteps of any of the residences or dwelling houses, or business houses, or on any streets, sidewalks or lots within the corporate limits of the city of Fort Dodge, Iowa." Such samples may be distributed, however, the ordinance says, by placing them in the hands of adult persons or in some safe place intended for that purpose.

KANSAS.

Office Raided; Whiskey Seized.—The office of Dr. Samuel B. Wilson, Olathe, was recently raided, 40 gallons of whiskey seized, and the physician placed under arrest on 13 charges of selling whiskey.

Hospital on Fire.—A fire occurred at the Leavenworth Hospital, December 7, which destroyed the roof, and damaged the building to the extent of about $3,000. The twenty patients were safely removed.

Smallpox.—Goodland has about 15 cases, and through lack of efficient quarantine, the disease has been carried to Benkelman township, where 16 cases have been reported.——Cherokee County reports 7 cases.

Physician Wins Case.—The suit brought by Frank Oldham against Dr. Lewis H. Munn, Topeka, in which the plaintiff alleged malpractice, was dismissed for lack of evidence, before the trial had reached its natural end.

Personal.—Dr. Edward P. Chase, Shawnee, was seriously injured, December 10, by being struck on the head with a scale-weight.——Dr. Francis M. Thomas, Leavenworth, surgeon of the federal prison, has been seriously ill with pulmonary hemorrhages, but is now reported as improving.

KENTUCKY.

Louisville City Hospital.—The Board of Public Safety has made Julius C. Vogt superintendent of the Louisville City Hospital, vice Dr. Ellis Duncan, removed.

Threatens Quarantine.—West Virginia has been notified by the Kentucky State Board of Health that unless precautions are taken to protect Kentucky against smallpox patients coming from the former state, a quarantine will be established. All who enter Kentucky will be vaccinated.

Smallpox.—Kenova has quarantined against Ceredo.——There are 8 new cases of the disease at Willard.——The disease is reported at two points in Whitley County.——In Frankfort the only cases since September have been four in one family, all fatal.——Richmond has 11 cases among negroes.——At Smith's Grove four cases are reported in one family.

Personal.—Dr. Thomas J. Slaton, Greenville, recently sustained an injury to his ankle in a runaway.——Dr. Irvin Abell has gone to British Honduras and Brazil to recuperate from a serious attack of sepsis.——Dr. Charles L. Moir, Louisville, has been appointed secretary of the City Hospital, vice Dr. George B. Jenkins, resigned.——Dr. James W. Crowley, Newport, has been elected president of the local board of health.——Drs. Joseph M. Mathews and Bernard Asman have reassociated themselves for the practice of their specialty. Dr. Asman recently returned from Europe.

LOUISIANA.

Personal.—Dr. John J. Archinard, New Orleans, has been elected house surgeon of the Old Soldiers' Home.

Tulane Opens.—The medical department of Tulane University, New Orleans, opened for the year, October 26, with an address by Dr. Matas.

Rabies To Be Treated at Charity Hospital.—At a recent meeting of the board of administrators of Charity Hospital, New Orleans, the report of the special committee appointed to investigate and advise the board of the expense of establishing and maintaining a department for the treatment and cure of hydrophobia was submitted and unanimously adopted. The committee was instructed to carry out its plans.

Society Elects Officers.—At the annual election of the Orleans Parish Medical Society, December 12, the following officers were elected: President, Dr. Marcus J. Magruder; vice-presidents, Dr. Jacob A. Storck, William M. Perkins, and Otto Joachim; secretary, Dr. Samuel M. D. Clark; treasurer, Dr. Edward J. Huhner; librarian, Dr. Homer Dupuy, and additional directors, Drs. Edwin J. Graner, Eugene H. Walet and Morgan M. Lowe, all of New Orleans.

MARYLAND.

Physicians' Homes Burn.—The dwelling-houses of Dr. Benjamin M. Price, near Mt. Carmel, and of Dr. S. B. Milford, at Poolesville, were destroyed by fire December 8.

Try to Enforce Laws.—The State Board of Health is trying to enforce the law requiring registration of births. It is also discussing a school for health officers to be held annually.

Smallpox at Quarantine.—Quarantine Physician Heiskell reports 51 cases of smallpox cared for this year at the hospital, with two deaths. Forty-one were brought from Baltimore and 10 from Homburgville, in Baltimore County, where the disease broke out in a camp last summer.

State Hospital Report.—Dr. J. Clement Clark reports 515 patients in Springfield State Hospital for the Insane, November 30, 290 males and 225 females. The typhoid outbreak has subsided under isolation, disinfection and sterilization of linen, etc. An isolation cottage is urged for infectious diseases.

Baltimore.

Money for Hospital.—By the will of Mrs. Mary C. Bailey $1,000 was left to the Nursery and Child's Hospital.

Gilman to Resign.—Dr. D. C. Gilman has announced his intention of resigning the presidency of the Carnegie Institution at Washington, next year.

Personal.—Dr. William B. Perry was elected to take charge of the surgical and gynecological departments of the Northeastern Dispensary, December 9.——Dr. José L. Hirsh has been elected president, and Dr. John R. Abercrombie, secretary, of the University of Maryland Medical Societies.

Tuberculosis Exposition.—The executive committee decided on January 25 as the date of the opening of the display. Interest is manifested all over the United States in the display. Many state boards and city health departments and hospitals and sanatoria have promised special exhibits, and there will be contributions from Germany, England, Holland, France, Belgium, Austria and Russia. Applications are being received from manufacturers for space for apparatus and devices. The pathologic exhibit will be particularly fine. The exposition will last a week, and there will be daily lectures. A meeting of the executive and general committees was held December 9. It was announced that the scope of the exposition had far outgrown the original plans, and the interest was so widespread that it had now assumed national importance. A number of addresses was made, and several subcommittees were appointed to take charge of the different branches of the work. A committee of citizens has been appointed, and $1,500 will be raised for expenses. McCoy Hall has been offered by the Johns Hopkins University for the display.

OHIO.

Starling Student Dies.—Nathaniel C. Keener of Uniontown, Pa., a senior student at Starling Medical College, Columbus, died at Mount Carmel Hospital in that city, December 5, from appendicitis.

Elects Officers.—The Marion County Medical Society met at Marion, December 1, and elected Dr. A. Melville Crane, president; Dr. Robert C. M. Lewis, vice-president; Dr. Dana O. Weeks, secretary; Dr. Francis B. Sawyer, treasurer, and Dr. Charles E. Sawyer, member of the board of censors, all of Marion.

Personal.—Dr. Alexander W. Leuke, Cleveland, has been appointed workhouse physician, vice Dr. Frederick J. Schmoldt, resigned.——Dr. George W. Boerstler, Lancaster, who has been at St. Anthony's Hospital, Columbus, on account of an infected wound, was obliged to have the affected arm amputated near the shoulder.——Dr. William Muhlberg has been elected curator of the Cincinnati City Hospital laboratory, vice Dr. Alfred Friedlander, resigned.

Epidemic Diseases.—The public schools of Butler have been closed on account of the prevalence of measles, pertussis and varicella among the pupils.——In Cleveland, during November, 369 cases of communicable disease were reported, 205 of which were of diphtheria.——Diphtheria has broken out at the Westminster Missionary Home, Wooster.——Smallpox is said to be epidemic in North Jackson and in Phausberg; at the latter point 14 cases have rapidly developed.

PENNSYLVANIA.

Women Incorporate Hospital.—Application has been made in Common Pleas Court for a charter for the Homestead Hos-

pital, to be erected at Homestead. All the incorporators are women.

Philadelphia Hospital Dinner.—At the annual banquet of internes and ex-internes of Philadelphia Hospital, held December 1, Dr. J. Chalmers Da Costa was toastmaster, and the mayor, Director of Public Health Martin, Dr. F. X. Dercum and Dr. George E. de Schweinitz were guests of honor.

Pathologic Exhibit.—The annual exhibition meeting of the Philadelphia Pathological Society will be held in the Mutter Museum of the College of Physicians, Jan. 14, 1904. This exhibition embraces every department of human and animal pathology, with microscopic demonstrations of the gross material, and represents the pathologic material of scientific interest accumulated in the various hospitals during the year. The exhibition is open to all members of the medical profession.

Accidents and Injuries.—Dr. Karl Emmerling, Pittsburg, is recovering from the injuries received in the accident which cost Dr. Blumberg his life.——Dr. Boardman Reed, Philadelphia, who underwent an operation for appendicitis, December 2, is recovering.——Dr. Robert J. A. Irwin, Pittsburg, suffered a fracture of the left arm in an altercation with a street car conductor, December 4.——Dr. Horace G. Colley, Wilkesbarre, was seriously injured by falling through an open grating on a sidewalk, November 27.

The Typhoid Epidemic at Butler.—The situation at Butler has undergone no great change since our last issue. New cases continue to be reported by the physicians, but there is, on the whole, some falling off in number. The representatives of the Pennsylvania State Board of Health, now in charge of the situation, are engaged in making an exhaustive canvass of the town with a view to determining the precise number of cases since the onset of the epidemic. It is stated that up to December 9, 478 infected houses had been visited in connection with this census, or about two-thirds of the number in which typhoid fever is supposed to exist. From these houses a record of 1,210 cases of the disease was obtained, and 38 deaths. The total number of deaths up to the present time probably exceeds 50. An appeal to the general public was issued in the middle of the week by William Kennedy, burgess of Butler, reading as follows:

> In justice to all, in behalf of the borough government and the entire people of Butler, I beg leave to state so far we have been able to help our people without a general call for outside aid. We contributed $8,000 to the relief fund and outside cities raised this amount to $16,000. We have been carefully using this since November 10. Now we are forced to admit our funds are getting low.
>
> We feel as a committee for the relief of our suffering people that necessity compels us to issue a general appeal for outside assistance. We have been criticized in various ways. We wish to assure the public that we have been doing our very best to relieve suffering, sorrow and want. We were inexperienced in an epidemic scourge such as this is. It came on us so suddenly that it took a little time for us to realize the awful truth that has been forced on us and to prepare ourselves to best fight the epidemic. We are now thoroughly organized and working together as a committee and as a people perfectly in harmony, sympathy and kindness, as a single individual, doing all in our power to relieve the suffering and needy ones in our community. We will be able to give to the public an accurate account of all money received and expended.
>
> It is stated that it will take $100,000 to carry us through this siege of disaster. We can not raise it. Necessity compels us to issue a general appeal for outside aid and assistance. We want the public to realize that we all have been and are doing our very best, giving time and money where needed. But we feel we have exhausted our supplies in every way, and many precious lives may still be sacrificed if outside aid is not furnished us.
>
> We, as a people, are thankful for the aid already received and for the great sympathy shown us. If need be we will accept the criticism also. And we appeal as a stricken people, unable longer to help themselves, for aid in our distress.
>
> WILLIAM KENNEDY, Burgess.

In response to this appeal many additional subscriptions have been made, and it is said that up to December 12 contributions amounting to over $30,000 had been received. The sum now in hand is thought to be sufficient to cover the expenditures for ten or twelve days longer. Three temporary hospitals have been put into commission, in addition to the Butler County General Hospital, which has been taxed to its utmost since the beginning of the epidemic. It is possible that another temporary hospital may have to be opened. Miss Barton, the head of the International Red Cross Society, has arrived in Butler, and plans to aid in the work of relief. It is probable that a Red Cross hospital will be established in connection with a hospital supplies room and diet kitchen.

GENERAL.

Primary Ovarian Pregnancy Data Wanted.—Dr. Louis Frank, 229 W. Chestnut Street, Louisville, Ky., would appreciate communication from any one who has personal knowledge of a case of primary ovarian pregnancy. Data regarding the pathologic finding is especially wanted.

Colorado Medicine.—This is the title of the new journal owned and published by the Colorado State Medical Society, and which takes the place of the annual transactions. The number before us consists of thirty-two pages, all filled with excellent scientific matter, together with news items, etc., relating especially to Colorado. It contains no advertisements. The journal is certainly a credit to the society, as well as to those under whose charge it is published. The editor is Dr. Edward Jackson.

FOREIGN.

Morphin-Scopolamin Narcosis.—An original article by Korff in the *Münchener Med. Wochft.* No. 46, is reviewed on page 1568 of this number of THE JOURNAL. No 48 of the *Wochenschrift* has just been received as we go to press, and it states that the dosage of scopolamin was incorrectly given in the article. It should read .01 gm. scopolamin hydrobromate, instead of .001 gm., in the formula. The total amount given is thus .001 gm. scopolamin and .025 morphin. The drug is better known in this country as hyoscin hydrobromate.

Public Anti-Charlatan Meeting at Berlin.—The German Society for the Campaign against Venereal Diseases announced a public meeting to discuss the subject "Venereal Disease and Quacks." Professor Kutner delivered the opening address, from the standpoint of the physician, followed by an eminent judge, who discussed the medicolegal bearings of the question. He asserted that many of the present evils would vanish when the advertising of charlatans is restricted. At present they are favored by the law as they are allowed to advertise while physicians are not. The meeting drew a crowd, but mostly of charlatans and their adherents who did all they could to throw ridicule and discredit on the speakers, especially when one read quotations from the published writings of charlatans showing how grossly they contradict themselves. The assembly finally grew so tumultuous that the proceedings were summarily broken off and the meeting adjourned *sine die*.

The Approaching International Congress of Otology.—The subjects appointed for discussion are "Choice of a Simple and Practical Acoumetric Formula," "Suppurations of the Labyrinth," and "Technic of Operating and After-Care of Otogenic Brain Abscess." The addresses on the first subject will be by Politzer, Gradenigo and Delsaux; on the second by Brieger, von Stein and Dundas Grant, and on the third by Knapp, Schmiegelow and Botey. The date has been definitely settled as August 1 to 4, 1904, at Bordeaux, France. English, French, German and Italian are to be the official languages. The fee of $5 may be sent to Dr. Lannois, rue Emile-Zola 14, Lyons, the treasurer of the congress. The secretary general is Dr. Lermoyez, rue la Boétie 20 *bis*, Paris, to whom communications should be addressed, if possible before May 1, accompanied by a brief summary. The Lenval prize will be awarded during the congress for the work that has realized the greatest progress in the practical treatment of affections of the auditory apparatus or for the invention of some portable appliance, which has materially improved the hearing of the deaf. The committee in charge of the awarding of the prize consists of Politzer of Vienna, Benni of Warsaw, Gellé of Paris, Pritchard of London, Kircher of Würzburg, Grazzi of Florence, Moure of Bordeaux and D. B. St. John Roosa of New York. The prize is the interest on $600, accumulated since the congress before the last, and the competing articles are restricted to this period. The president of the congress is Professor E. J. Moure of Bordeaux, founder and editor of the well-known *Revue Hebdomadaire de Laryngologie d'Otologie et de Rhinologie*, now in its twenty-fourth year.

PARIS LETTER.

Marmorek's New Antituberculous Serum.

A good deal of curiosity had been excited by the announcement that Dr. Marmorek, late of the Pasteur Institute, was to read a communication at the Académie of Médecine on his new serum for tuberculosis. This was to take place November 10, but on account of the quantity of communications, it was put off till November 17. The *Temps* gives an excellent account of the proceedings at the Académie de Médecine, much better certainly than most of the medical papers. The space reserved for the public was filled, numerous photographers being present. Dr. Marmorek's communication has been reviewed in THE JOURNAL, December 5 and 12, pages 1421 and 1479. According to Dr. Marmorek, definite judgment can not as yet be pronounced on his serum. Experiments are being carried out with it in various parts of the world.

Comments on the Serum.

Dr. Marmorek's communication was not immediately discussed, as he is not a member of the Academy of Medicine. According to the *Temps* Professor Dieulafoy has employed the serum in his clinique at the Hotel Dieu, and with poor results, it would seem. Dr. Hallopeau has used it at the St. Louis Hospital against lupus, and has obtained no result. Dr. Lucas Championniere employed it in 5 cases of bony tuberculosis, and considered it did not act differently from other sera. Experments carried on in guinea-pigs were unsatisfactory. In one of the hospitals a case of Pott's disease and one of consumption died while being subjected to this treatment at the very same hour. The symptoms observed were those of cyanosis and asphyxia. The medical editor of the *Matin* has written an editorial on the serum of Marmorek in which he does not seem to be very partial to him, Koch's fiasco being brought up as a warning. It should be remembered that Marmorek's anti-streptococcic serum was looked on with disfavor when first brought out, and it has never been accepted here in Paris by the majority of prominent medical men.

Dieulafoy's Views.

On December 1, Professor Dieulafoy gave the results in his service furnished by the use of Marmorek's serum. During August, September and October, 1902, 7 tuberculous patients were treated by this serum; 4 patients were suffering from ordinary pulmonary tuberculosis, 2 had laryngeal and pulmonary tuberculosis, and lastly 1 was affected with pleural tuberculosis followed by an effusion. Marmorek made the injections himself, determined the doses, and repeated the doses as often as he wished. The quantity of serum injected was about 5 to 10 c.c., and the injections were made each day, every other day, or at wider intervals. Dieulafoy examined carefully the patients, auscultated them frequently, had minute observations taken, and found the following results: 1. The serum did not seem to have any effect on the fever, and one patient, who had had no fever, showed a high temperature after the first injections. 2. The serum did not seem to have a beneficial effect on the sputum, which increased in quantity as much as two or three times in some cases. 3. The serum does not seem to have had a favorable action on the tuberculous lesions, and in some cases, pulmonary or pleural lesions appeared during the course of the treatment. 4. The serum does not seem to have had a favorable effect on the nutrition, as these patients continued to lose flesh and sometimes rapidly, notwithstanding overfeeding. Dieulafoy, on these reasons, asked Marmorek to discontinue his injections. Of the 7 patients treated in this manner 5 are already dead. Their clinical history is as follows: A case of fibrous tuberculosis without fever is still alive in Dieulafoy's service. A case of pleurisy recognized by cytodiagnosis and inoculation to be of pleuritic nature, has come back to the hospital after a year, and has a large pulmonary excavation. Case of laryngeal and pulmonary tuberculosis: Treatment began Aug. 6, 1902. Died Oct. 2, 1902. Second case similar to the preceding one. Died in November, 1902. Lastly, 3 cases of ordinary pulmonary tuberculosis, who died in August, January and April, 1903. Experiments were also carried out on animals, two series of guinea-pigs being inoculated with sputum. The first series was injected with the serum and died before the second series, which had had no treatment. Such is the result observed by Professor Dieulafoy.

Comments of Other Observers.

Monod, the surgeon, has tried Marmorek's serum in his service and remarked that there had been an amelioration in all his cases, and that he was willing to continue his experiments with this serum. Le Dentu, a genito-urinary surgeon, had tried it in one case, and the patient was injected 12 to 15 times. As there was no improvement, the treatment was stopped. Dr. Hallopeau also tried this treatment on seven patients affected with tuberculous lesions of the skin, and there was no amelioration, but new foci formed around old lesions.

Correspondence.

Tuberculosis Congresses.

CHICAGO, Dec. 12, 1903.

To the Editor:—Your editorial in the last number of THE JOURNAL on "Tuberculosis Congresses" is most timely, and it is to be hoped that it will prevent misunderstandings in the future. Those actively working in the local associations for the prevention of tuberculosis have so far not cared to define their position in regard to these so-called "American" congresses; their time has been more usefully employed in perfecting their organization and preventative methods, and no doubt in time this will bring about the formation of a national body for the purpose of standardizing and generalizing their measures. It is indeed unfortunate that any number of men can combine and call themselves "American Congress" and by virtue of that name alone, not only persuade the unsuspecting medical and lay public of its representative character, but even as in the case of the "Bell Congress" receive the sanction and assistance of the Government. The pathetic in this case is more striking than the humorous, because as you have justly pointed out, the impression abroad is that this planned congress is of a representative character and that preparations are made to send delegates to it. I have had several inquiries in regard to this, and only a few days ago I received a letter from Dr. Pannwitz, secretary general of the International Central Bureau for the Prevention of Tuberculosis (representing sixteen countries) inquiring about these congresses, and expressing the hope that America would be definitely represented in the international movement against tuberculosis after the congress to be held in St. Louis. Such misunderstandings, brought about by the announcements of these congresses, must have the effect of minimizing the importance of the movement, and it does not matter whether the promoters of the scheme have good or evil intentions, they are in no way qualified to represent American work and thought in the antituberculosis crusade.

The most important tuberculosis associations which are doing active work in this country are the following:

BOSTON: Association for the Relief and Control of Tuberculosis, 43 Hawkins Street, Harold K. Estabrook, secretary.

NEW YORK: Committee on the Prevention of Tuberculosis of the Charity Organization Society, 105 East 22d Street, Paul Kennady, secretary.

PHILADELPHIA: The Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis, Dr. Lawrence F. Flick, medical Director.

BALTIMORE: The Tuberculosis Commission of Maryland, 10 South Street, Dr. M. L. Price, medical officer.

CHICAGO: Committee for the Prevention of Tuberculosis of the Visiting Nurse Association, 79 Dearborn Street, Dr. Wm. A. Evans, secretary.

These associations have, through their officers and members, a truly representative character in their respective cities. They reach a very large number of consumptives and so can apply preventative measures, educational and other, in an efficient manner, wherever most needed. They are also working in close co-operation with health boards and charity organizations, thereby greatly increasing their importance. The "American Congresses" have nothing to do with these working bodies, they are satisfied with themselves, their announcements and letterheads, which as far as we can discover are their only weapons in the fight against tuberculosis.

It is to be hoped that your editorial will prevent some unsuspecting members of our profession from being persuaded to consent to serve as officers of these congresses, and I feel certain that your efforts will have the unanimous approval of all those actively interested in the movement.

ARNOLD C. KLEBS.

79 Dearborn Street.

Marriages.

CLIFTON L. GREEN, M.D., to Miss Bessie Hart, both of Utica, Miss., December 2.

ROBERT F. CAMPBELL, M.D., to Miss Gertrude C. Wallis, both of Chicago, December 10.

PAUL SORKNESS, M.D., to Miss Grace Marie Thacker, both of Fargo, N. D., December 2.

NOAH E. SUTTON, M.D., to BERTHA E. WIGGIN, M.D., both of Trenton, Mo., November 25.

WILFRED S. HALE, M.D., to Miss Helen Gould, both of Albany, N. Y., November 21.

JAMES W. ALLEN, M.D., to FRANCES D. EMERY, M.D., both of Dallas, Texas, November 30.

ALVIN CRAIG LEE, M.D., to Miss Hattie May Niman, both of Mansfield, Ohio, December 16.

LAWRENCE T. ROYSTER, M.D., Norfolk, Va., to Miss Ola Park, at Washington, D. C., December 9.

THOMAS D. ARMISTEAD, M.D., Roanoke, Va., to Miss Shelburne of Richmond, Va., December 6.

JOHN HENRY YOUNG, M.D., Cumberland, Wyo., to Miss Nancy May Boyer, at Carroll, Ohio, November 19.

R. G. CURTIS, M.D., Honokaa, Hawaii, to Miss Blair of New York, at Honolulu, Hawaii, November 16.

GEORGE WILLIAM PARKER, M.D., Chicago, to Miss Amy Josey of Calumet, Mich., at Chicago, December 1.

WILLIAM C. MCCAULEY, M.D., Versailles, Ky., to Miss Sara Smith Camp of Jackson, Mich., December 9.

BUDD CLARKE CORBUS, M.D., Chicago, to Miss Julia Gertrude Pitkin of Benton Harbor, Mich., December 15.

LESTER EFIRD, M.D., Leesville, S. C., to Miss Georgia Constance Rights of Winston-Salem, N. C., November 25.

JOHN FRANKLIN WOODWARD, M.D., Norfolk, Va., to Miss Martha Washington Philips of Tarborough, N. C., December 16.

JESSE RALPH HARRIS, M.D., U. S. Army, Fort Meyer, Washington, D. C., to Miss Belle Agnes Miller of Buffalo, December 2.

Deaths.

William Ingalls, M.D. Harvard University Medical School, Boston, 1836, surgeon of the Fifth and later of the Fifty-ninth Massachusetts Volunteer Infantry in the Civil War; for fifteen years surgeon at the Boston City Hospital; a member of the Massachusetts Medical Society, the Obstetrical Society of Boston, and other scientific bodies, and one of the best known of the older physicians of Boston, died in his apartments in Roxbury, December 1, after a short illness, aged 90.

John F. Meehan, M.D. Baltimore Medical College, 1894, who served in the Spanish-American War, and afterward in the hospital corps and as an acting assistant surgeon in the Army, died at his home in Urbana, Ohio, December 3, from skull-fracture due to a fall, November 26, aged 30.

Henry C. Utz, M.D. Louisville Medical College, 1891, a member of the American Medical Association, and one of the rising young practitioners of Hamilton County, Ind., died at his home in Atlanta, December 7, from pneumonia, after an illness of three weeks, aged 37.

Delano Gavin Brown, M.D. College of Physicians and Surgeons of Buffalo, N. Y., 1883, died at his home in Honeoye Falls, N. Y., November 30, after an illness of three months from Bright's disease, aged 50.

Horace M. Paine, M.D. University of the City of New York, 1849, of Albany N. Y., a member of the American Medical Association, died in Atlanta, Ga., December 5, from pneumonia, aged 76.

Calvin B. Phillips, M.D. Washington University School of Medicine, Baltimore, 1868, a member of the American Medical Association, died suddenly at his home in Cuero, Texas, December 6.

Virgil Kingsley, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1877, died at his home in Carthage, Ill., December 4, after an illness of one week from pneumonia, aged 51.

Eugene Field Hume, M.D. College of Physicians and Surgeons in the City of New York, 1901, of Lexington, Ky., died at Richmond, Ky., December 3, from pneumonia, aged 28.

Katherine M. Crawford, M.D. Hahnemann Medical College, Chicago, 1885, of York, Pa., died in the York Hospital, December 2, after a surgical operation, aged 47.

Charles M. Fuller, M.D. Boston University School of Medicine, 1878, died at his home in Medfield, Mass., December 4, after a short illness, from pneumonia.

R. F. Julian, M.D., of Bloomington, Tenn., was shot and instantly killed while returning from a professional call at Baxter, Tenn., December 5, aged 45.

M. E. Gonzalez, M.D. Cooper Medical College, San Francisco, 1883, died suddenly from apoplexy at his apartments in San Francisco, December 6, aged 55.

Jean Bertrand Duchien, M.D. Académie de Montpellier, France, 1885, died recently from pneumonia at his home in Baton Rouge, La.

Joseph R. Schooling, M.D. University of Louisville, 1875, died at his home in Marrowbone, Ky., from paralysis, December 3, aged 50.

Edward C. Lyman, M.D. University of Michigan, Ann Arbor, 1892, died at his home in Flint, Mich., December 4, aged 28.

Charles McMyers, M.D. University of Maryland, Baltimore, 1894, died suddenly at Baltimore, December 4, aged 69.

James M. Van Dyck, M.D., died at his home in Dorchester, Mass., December 3, from morphin, self-administered.

Phineas Cleveidon, M.D. Eclectic Medical Institute, Cincinnati, 1899, died recently at Albuquerque, N. M.

E. Lee Ensign, M.D. Albany Medical College, 1856, died at his home in Erieville, N. Y., December 3, aged 73.

John R. Freed, M.D. University of Louisville, 1882, died at his home in Carthage, Mo., December 8.

Miscellany.

Value of Calabar Bean in Atony of Morphin Addiction.—O. Emmerich has been for twelve years in charge of a sanitarium for nervous diseases and drug habits at Baden Baden, and his experience has demonstrated that in morphin addiction there are three stages. In the first, the intestine is quieted by the morphin, inducing the familiar obstipation. Then follows a stage of tolerance in which the intestines may functionate comparatively normally. The third stage of the drug addiction brings atony, diminished glandular activity, in fact the gland and muscle tissue partially disappear and ptosis is pronounced. This last stage is the distinct indication for extract of the calabar bean according to the remarkable experiences he relates from his practice. None of the derivatives or other preparations of the bean are reliable, and he has had mishaps with them. He does not aim to afford temporary relief but to tone up the intestines so that other measures will be able to take hold. He finds that this toning up is not restricted to the intestines alone, but all the suspending ligaments, the bladder, the heart and the vessel musculature share in the benefits from it. He remarks that the action of the bean can be seen in the expulsion of an enema. When a pint of water injected in an old morphinist, which formerly could be retained for ten to fifteen minutes without effort, is spontaneously expelled almost at once, the bean has accomplished its purpose and should be suspended. Then is the moment for mechanical and dietetic measures to take advantage of what has been gained in this way. The artificial toning up of the intestines is rendered permanent by appropriate physical measures. The patient is encouraged to take exercise, climb, and food given in abundance which will force the intestines to work, cooked fruits, etc. He has never derived any benefit from massage or abdominal bandages in such cases. He concludes his article in the *Allg. Med. Ct.Ztg.*, lxxii, p. 297, by urging others to try the extract of calabar bean in ptosis and atony from other causes than the drug habit.

State Boards of Registration.

COMING EXAMINATIONS.

Colorado State Board of Medical Examiners, 1723 Tremont St., Denver, Dec. 22-24. Secretary, Dr. S. D. Van Meter, Denver.

Utah State Board of Medical Examiners, Salt Lake City, Jan. 4, 1904. Secretary, Dr. R. W. Fisher, Salt Lake City.

State Medical Examining Board of Washington, Tacoma, Jan. 5-6, 1904. Secretary, Dr. P. B. Swearingen, Tacoma.

Board of Medical Examiners of Arizona, Phoenix, Jan. 4-5, 1904. Secretary, Dr. Wm. Duffield, Phoenix.

State Medical Examining Board of North Dakota, Grand Forks, Jan. 5, 1904. Secretary, Dr. H. M. Wheeler, Grand Forks.

Board of Medical Examiners of the State of Oregon, Portland, Jan. 5, 1904. Secretary, Dr. Byron E. Miller, Portland.

Colorado State Board of Medical Examiners, 1723 Tremont St., Denver, Jan. 5-6, 1904. Secretary, Dr. S. D. Van Meter, Denver.

Minnesota State Board of Medical Examiners, State Capitol Bldg., St. Paul, Jan. 5-7, 1904. Secretary, Dr. C. J. Ringnell, Minneapolis.

State Board of Health of Rhode Island, State House, Providence, Jan. 7, 1904. Secretary, Dr. G. T. Swarts, Providence.

Indiana State Board of Medical Registration and Examination, Indianapolis, Jan. 13, 1904. Secretary, Dr. W. T. Gott, Crawfordsville.

Board of Medical Examiners of South Dakota, Cataract Hotel, Sioux Falls, Jan. 13-15, 1904. Secretary, Dr. H. E. McNutt, Aberdeen.

Wisconsin Board of Medical Examiners, Milwaukee, Jan. 12, 1904. Secretary, Dr. F. R. Forsbeck, Milwaukee.

Vermont State Board of Medical Censors, Y. M. C. A. Bldg., Burlington, Jan. 13-14, 1904. Secretary, Dr. S. W. Hammond, Rutland.

Board of Medical Supervisors of the District of Columbia, Washington, Jan. 14, 1904. Secretary, Dr. Wm. C. Woodward, Washington.

Illinois State Board of Health, Great Northern Hotel, Chicago, Jan. 14-16, 1904. Secretary, Dr. J. A. Egan, Springfield.

Iowa State Board of Medical Examiners, Capitol Bldg., Des Moines, Jan. 26-27, 1904. Secretary, Dr. J. F. Kennedy, Des Moines.

Utah Report.—Dr. R. W. Fisher, secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, November 6, at which 8 candidates were examined, all passing, on 10 subjects and 70 questions, the percentage required to pass being 75.

Colleges.	Year Grad.	Per Cent.
Starling Medical College, Columbus, Ohio	1885	77

The Public Service.

Army Changes.

Memorandum of changes of stations and duties of medical officers for the week ending Dec. 12, 1903:

Hansell, Haywood S., asst.-surgeon, granted thirty days' leave of absence.

Rand, Irving W., asst.-surgeon, granted thirty days' extension to present leave of absence.

Bispham, Wm. N., asst.-surgeon, granted fifteen days' leave of absence.

Fisher, Henry C., asst.-surgeon, granted three months' leave of absence about Dec. 20, 1903.

Shockley, M. A. W., asst.-surgeon, relieved from duty at Fort Niobrara, Neb., on expiration of present leave, and ordered to Manila, P. I.

Byrne, Chas. B., asst.-surgeon general, Dec. 2, 1903, announced as chief surgeon, headquarters, Department of the Missouri, Omaha.

Steer, Samuel L., asst.-surgeon, granted twenty-one days' leave of absence.

Shillock, Paul, surgeon, granted four months' leave with permission to go beyond sea.

Polhemus, A. S., surgeon, leave extended thirty days.

Torney, Geo. H., deputy surgeon general; Brechemin, Louis, and Stephenson, Wm., surgeons, and Kennedy, Jas. M., asst.-surgeon, appointed members of a board of medical officers to meet at the U. S. General Hospital, Presidio of San Francisco, at the call of the president of the board, for examination of candidates for admission to the Medical Corps of the Army.

Banister, Jno. M., Carter, Wm. F., Raymond, H. I., Bradley, A. E., surgeons, and Kirkpatrick, Thos. J., asst.-surgeon, appointed members of a board of medical officers to meet in Manila, P. I., for the examination of candidates for admission to the Medical Corps of the Army.

Bourke, James, asst.-surgeon, relieved from duty at Fort Sheridan, Ill., and ordered to Chicago for temporary duty as attending surgeon and examiner of recruits in that city.

Purviance, Wm. E., asst.-surgeon, granted two months' leave of absence.

Ekwurzel, Geo. M., asst.-surgeon, assignment to station at Fort Banks, Mass., revoked.

Cox, Walter, asst.-surgeon, assignment to station at Fort Reno, Okla. Territory, revoked.

Farr, Charles W., asst.-surgeon, assignment to station at Fort Mason, Cal., revoked.

Girard, Joseph R., asst.-surgeon general, announced as chief surgeon, headquarters Department of Texas, San Antonio, Texas.

Banta, Wm. P., asst.-surgeon, granted thirty days' leave of absence.

Mason, Charles F., surgeon, relieved from temporary duty as chief surgeon, Department of Texas.

Kendall, Wm. P., surgeon, left U. S. Army General Hospital, Presidio of San Francisco with party of insane en route to Government Hospital for the Insane, Washington, D. C.

Slater, Ernest F., contract surgeon, on arrival at Fort Ethan Allen, Vt., with troops of the 15th Cavalry, is relieved from duty in the Division of the Philippines and directed to proceed to Fort Hancock, N. J., for duty.

Sparrenberger, Frederick H., contract surgeon, ordered to proceed from Denver to Fort Mott, N. J., for duty.

Waterhouse, M. Manley, contract surgeon, relieved from duty at Fort Mott, N. J., on the arrival thereat of Contract Surgeon Sparrenberger, and ordered to the Philippine Islands for duty.

Artaud, Frank E., contract surgeon, ordered from Lake Providence, La., to the Philippine Islands for duty.

Cornman, Leighton R., contract surgeon, ordered from Lowell, Mass., to Fort Sheridan, Ill., to accompany troops of the 2d Cavalry thence to Philippine service.

Hughes, Leonard S., contract surgeon, granted two months' leave from the Division of the Philippines, with permission to visit the United States and to apply for an extension of one month.

Ramsey, William H., contract surgeon, assigned December 9 to duty as attending surgeon and examiner of recruits at Omaha.

Pinquard, Joseph, contract surgeon, ordered from Vinita, Ind. Ter., to the Philippine Islands for duty.

Prentice, Arthur D., contract surgeon, ordered from San Francisco to the Philippine Islands for duty.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending Dec. 12, 1903:

Wheeler, W. M., surgeon, ordered to the Navy Yard, Puget Sound, Washington, and also on board the *Nipsic*.

Thompson, J. C., P. A. surgeon, detached from the Navy Yard, Puget Sound, Wash., and ordered to the *Albatross*.

Butler, C. S., asst.-surgeon, detached from the *Albatross* and ordered home to wait orders.

Peck, C. S., asst.-surgeon, detached from the *Iris* and ordered home and to wait orders.

Percy, H. T., surgeon, detached from the *Indiana* and ordered to the *Iowa*.

Jenness, B. F., asst.-surgeon, detached from the *Indiana* and ordered to the *Iowa*.

Brownell, C. D. W., surgeon, ordered to the *Amphitrite*, with additional duty at the naval station, Guantaname, Cuba.

Pickrell, G., surgeon, ordered to additional duty in charge of the naval hospital, San Juan, P. R.

McDonnell, W. N., A. A. surgeon, detached from the Naval Academy and ordered to the *Glacier*.

Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the 14 days ended Dec. 10, 1903:

Sawtelle, H. W., surgeon, to inspect unserviceable property at Stapleton, N. Y.

Guiteras, G. M., surgeon, on completion of duties at Laredo, Texas, to rejoin station at Cairo, Ill.

Gardner, C. H., P. A. surgeon, relieved from duty at the Immigration Depot, New York, and directed to proceed to Key West, Fla., and assume command of the service at that port.

Oakley, J. H., P. A. surgeon, to proceed to Seattle, Wash., and assume temporary charge of service at that port, relieving A. A. Surgeon C. B. Ford.

Von Ezdorf, R. H., P. A. surgeon, detailed as inspector of certain points on Mexican National and Mexican Gulf railroads.

Lumsden, L. L., P. A. surgeon, Bureau letter granting leave of absence for ten days, amended so that said leave shall be for six days from November 15.

Fricks, L. D., P. A. surgeon, granted extension of leave of absence for one month from December 1.

Kerr, J. W., asst.-surgeon, to proceed to Washington, D. C., and report to chairman of examining board to determine his fitness for promotion to the grade of P. A. surgeon.

Richardson, T. F., asst.-surgeon, relieved from temporary duty in Texas and directed to rejoin station at New Orleans.

Goldberger, Jos., asst.-surgeon, relieved from temporary duty at Laredo, Texas, and directed to report at the Bureau, Washington, D. C.

Amesse, J. W., asst.-surgeon, to proceed to Seattle, Wash., and assume command of the service at that port, relieving P. A. Surgeon J. H. Oakley.

Glover, M. W., asst.-surgeon, relieved from duty at Baltimore, and directed to proceed to Victoria, B. C., for immigration duty.

Burkhalter, J. T., asst.-surgeon, granted leave of absence for one month from December 3.

Ebersole, R. E., asst.-surgeon, relieved from duty in Texas, and directed to rejoin his station at Gulf quarantine.

Foster, A. D., asst.-surgeon, relieved from duty at Charleston, S. C., and directed to proceed to Baltimore for immigration duty.

Brown, F. L., pharmacist, directed to rejoin his station at Pittsburg, Pa.

Walerius, M., pharmacist, relieved from temporary duty at Laredo, Texas, and directed to rejoin station at St. Louis.

Brooks, S. D., surgeon, to proceed to Brunswick, Ga., and assume temporary command of station.

McMullen, John, P. A. surgeon, relieved from duty at Hongkong, China, and directed to proceed to San Francisco and report arrival by wire.

Parker, H. B., P. A. surgeon, to proceed to New York and report to Surgeon G. W. Stoner, Immigration Depot, for duty.

White, M. J., P. A. surgeon, relieved from duty at Honolulu, T. H., and directed to proceed to Hongkong, China, for duty.

Richardson, T. F., asst.-surgeon, granted leave of absence for seven days from Dec. 6, 1903, under paragraph 191 of the regulations.

Amesse, J. W., asst.-surgeon, to proceed to Seattle, Wash., and assume command of the service at that port. Granted leave of absence for one day.

Berry, T. D., asst.-surgeon, detailed as inspector of unserviceable property at Cleveland, Ohio. To proceed to Cairo, Ill., and assume temporary command of service at that port during absence of Surgeon G. M. Guiteras.

Ebersole, R. E., asst.-surgeon, relieved from duty at Gulf Quarantine Station, and directed to proceed to Tampa Bay Quarantine Station and assume command.

Ebert, H. G., asst.-surgeon, granted leave of absence for four days from Nov. 28, 1903, under paragraph 191 of the regulations.

Smith, E. G., asst.-surgeon, to proceed to Santa Clara, N. Y., for special temporary duty to examine aliens.

Bready, J. E., A. A. surgeon, granted leave of absence for two days from December 15.

Gregory, G. A., A. A. surgeon, granted leave of absence for seven days from December 5.

Ryder, L. W., pharmacist, granted leave of absence for 15 days from December 10.

CASUALTY.

Burford, Hugh, A. A. surgeon, died at Brunswick, Ga., Dec. 7, 1903.

Murray, S. D., surgeon, died at Laredo, Texas, Nov. 22, 1903.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Dec. 11, 1903:

SMALLPOX—UNITED STATES.

California: San Francisco, Nov. 22-29, 1 case.
Maine: Madawaska Tp., Nov. 1-30, 65 cases.
Michigan: Detroit, Oct. 31-Nov. 5, 3 cases; 37 localities, Nov. 21-28, present.
Mississippi: Natchez, Nov. 29-Dec. 6, 11 cases.
Missouri: St. Louis, Nov. 28-Dec. 5, 2 cases.
New Hampshire: Manchester, Nov. 29-Dec. 5, 2 cases.
New Jersey: Camden, Nov. 29-Dec. 5, 3 cases, 1 death.
New York: New York, Nov. 29-Dec. 5, 1 case, 1 death.
Ohio: Cincinnati, Nov. 27-Dec. 4, 5 cases; Nov. 28-Dec. 5, Dayton, 1 case; Youngstown, 19 cases.
Pennsylvania: Nov. 28-Dec. 5, Erie, 13 cases: Johnstown, 7 cases; McKeesport, 1 case; Nov. 29-Dec. 5, Philadelphia, 99 cases, 15 deaths; Pittsburg, 28 cases, 6 deaths, 1 imported.
Tennessee: Memphis, Nov. 29-Dec. 5, 5 cases.
Utah: Salt Lake City, Nov. 21-28, 2 cases.
Wisconsin: Milwaukee, Nov. 14-28, 3 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Oct. 10-24, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, Nov. 7-21, 16 cases.
Belgium: Brussels, Nov. 7-14, 2 deaths.
Brazil: Rio de Janeiro, Oct. 25-Nov. 8, 89 cases, 59 deaths.
Chile: Antofogasta, Oct. 1-31, 13 deaths.
Colombia: Barranquilla, Nov. 15-22, 1 death.
France: Paris, Nov. 7-21, 10 cases, 1 death.
Great Britain: Glasgow, Nov. 13-27, 38 cases, 5 deaths; Newcastle-on-Tyne, Oct. 31-Nov. 21, 8 cases; Nottingham, Nov. 14-21, 1 death.
Italy: Catania, Nov. 12-19, 5 deaths.
Malta: Oct. 31-Nov. 7, 1 case.
Russia: Nov. 7-14, Moscow, 5 cases, 3 deaths; St. Petersburg, 54 cases; Odessa, Nov. 7-21, 4 cases, 2 deaths.
Turkey: Constantinople, Nov. 8-15, 1 case; Smyrna, Nov. 1-15, 29 deaths.
Venezuela, Oct. 26. Guarico District, epidemic; Pascua District, epidemic; Tucupido District, epidemic.

YELLOW FEVER—UNITED STATES.

Texas: Laredo, Dec. 1-7, 2 cases.

YELLOW FEVER—FOREIGN.

Mexico: Nov. 15-21, Ciudad Victoria, 5 cases, 4 deaths; Linares, 29 cases, 4 deaths; Marida, 5 cases, 2 deaths; Nuevo Laredo, 1 death; Tampico, 2 cases, 2 deaths; Tehuantepec, 1 case.
Venezuela: Oct. 16, Barquisemeto, present; Tucuyo, present.

CHOLERA—INSULAR.

Philippine Islands: Oct. 10-24, Manila, 60 cases, 57 deaths; Provinces, 1,700 cases, 1,384 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Oct. 24-31, 19 deaths.
Straits Settlements: Singapore, Oct. 17-24, 12 deaths.
Turkey in Asia: to Nov. 9, Aintab, 9 cases, 4 deaths; Aleppo, 16 cases, 15 deaths; Anah, 51 cases, 93 deaths; Antioch, 7 cases, 7 deaths; Birodjik, 4 cases, 4 deaths; Damascus, 2 cases, 2 deaths; Dolonki, 11 cases, 11 deaths; Haifa, 7 cases, 5 deaths; Urfa, 4 cases, 2 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Oct. 10-24, 3 cases, 2 deaths.

PLAGUE—FOREIGN.

Australia: Perth, Oct. 13, 1 case.
Brazil: Para, Nov. 1-8, 2 cases; Rio de Janeiro, Sept. 28-Oct. 18, 124 cases, 53 deaths.
Chile: Iquique, Sept. 1-30, 12 cases, 7 deaths.
Egypt: Alexandria, Oct. 31-Dec. 6, 2 cases, 3 deaths.
India: Calcutta, Oct. 24-31, 19 deaths.
Japan: Yokohama, Oct. 17-24, 3 cases; 4 deaths.
Mauritius: Oct. 29-Nov. 5, 72 cases, 36 deaths.

Medical Organization.

California.

BUTTE COUNTY MEDICAL SOCIETY.—Pursuant to call, physicians of the county met at Chico, November 28, and organized a society to be in affiliation with the state and national organizations. Dr. Oscar Stansbury, Chico, was elected president; Dr. Eli A. Kusel, Oroville, vice-president, and Dr. D. H. Moulton, Chico, secretary and treasurer. A committee was appointed to frame a constitution and by-laws, and to report on same at the next meeting, December 19.

Illinois.

PUTNAM COUNTY MEDICAL SOCIETY.—This society was organized at McNabb, November 28, with the aid of Dr. William O. Ensign, Rutland, councilor for the Second District.

Indiana.

POSEY COUNTY MEDICAL ASSOCIATION.—This society held its annual meeting at Mount Vernon, November 24, made plans for reorganization, and applied for a new charter. Dr. Jerome M. Gloze, New Harmony, was elected president, and Dr. F. Leslie Stallings, Caborn, secretary.

BOONE COUNTY MEDICAL SOCIETY.—The Boone County Medical Society held a business session and banquet at Crawfordsville, December 3. Dr. Paul J. Barcus, Crawfordsville, councilor for the Ninth District, explained the standard plan of reorganization, which was adopted unanimously.

BLACKFORD COUNTY MEDICAL SOCIETY.—This society met at Hartford City, November 26, and reorganized on the standard plan under the direction of Dr. Robert Hessler, councilor for the Eleventh District. Dr. Manford M. Clapper was re-elected president, and Dr. Eneidas K. Scott, secretary, both of Hartford City.

Iowa.

BOONE COUNTY MEDICAL SOCIETY.—The first annual meeting of this society was held at Boone, December 2. The following officers were elected: Dr. William L. Pollock, president; Dr. G. Henry Nordstrom, secretary; Dr. Edward M. Myers, treasurer, and censors, Drs. George D. Rowe, James C. Walker and George H. Stanger, all of Boone.

CLARKE COUNTY MEDICAL SOCIETY.—This society was organized, November 5, on the standard plan, with 13 members. The following officers were elected: President, Dr. J. Frank Aldrich, Murray; vice-president, Dr. Frederick S. Bowen, Woodbury; secretary, Dr. John L. Millard, Osceola; treasurer, Dr. William O. Parrish, Osceola, and delegate, Dr. J. Frank Aldrich, Murray. Dr. Frank E. Sampson, Creston, councilor for the Eighth District, was present and explained the plan of reorganization.

Maryland.

WICOMICO COUNTY MEDICAL SOCIETY.—Physicians of the county met at Salsbury, December 5, and organized a society on the standard plan with 15 charter members and the following officers: Dr. Francis M. Siemons, Salisbury, president; Dr. Eugene W. Humphreys, Salisbury, secretary and treasurer, and Dr. Harry C. Tull, Tyaskin, vice-president, and delegate to the state convention.

Minnesota.

DAKOTA COUNTY MEDICAL SOCIETY.—This society was organized at Hastings, December 3, on the standard plan, with the following officers: President, Dr. Alfred M. Adsit, Hastings; vice-president, Dr. Lewellyn D. Peck, Hastings; secretary, Dr. Warren M. Dodge, Farmington; treasurer, Dr. Julius C. Fitch, Hastings; censors, Drs. Charles O. Van Cappellen and Henry G. C. Van Beeck, Hastings, and one to be chosen, and state delegate, Dr. Alfred M. Adsit, Hastings. Dr. William S. Fullerton, St. Paul, state organizer, aided in the reorganization.

Oregon.

CENTRAL WILLAMETTE MEDICAL ASSOCIATION.—The physicians of Linn, Benton and Lincoln counties met at Albany, December 3, and effected a permanent organization on the standard plan, and elected the following officers: Dr. James P. Wallace, Albany, president; Dr. Henry S. Pernot, Corvallis, vice-president; Dr. August Stark, Albany, treasurer; Dr. William A. Trimble, Albany, secretary, and Drs. Thomas C. Mackey, Harrisburg, George R. Farra, Corvallis, and Albert G. Prill, Icio, censors.

Society Proceedings.

COMING MEETING.

Western Surgical and Gynecological Association, Denver, Dec. 28-29.

ACADEMY OF MEDICINE OF CLEVELAND.

Sixth Regular Meeting of the Section on Experimental Medicine, held Nov. 13, 1903.

Dr. John G. Spenzer, Chairman of the Section, in the Chair.

Experimental Study of Caisson Disease.

DR. J. J. R. MACLEOD read a paper entitled "Caisson Disease and Diver's Palsy, an Experimental Study," based on experiments performed during the last year at the London City Hospital Laboratories in England, in collaboration with Leonard Hill, F.R.S., on grants from the Royal Society.

Dr. Macleod stated that animals subjected to several atmospheres pressure of air may die, either when under the pressure or when they are decompressed. The second is the commoner cause of death. Experiments showed that air embolism is the invariable cause of death from decompression. The symptoms preceding death are dyspnea, cyanosis, and

violent convulsions. Animals with these symptoms were saved by reapplying the air pressure and decompressing more slowly.

In the case of dogs weighing about ten kilos a little over and hour was found necessary for the tissue fluids to become saturated with gas, and about the same time had to be used in decompression to admit of the liberation of this gas without the formation of bubbles (air emboli). These facts were confirmed by analyses of the blood gases, O_2, CO_2, and N, in dogs placed under various air and oxygen pressures. With all possible care to prevent decompression palsy, it was nevertheless found that the animal might die while under pressure. Two factors are found to depress the vitality of animals under pressure: 1. Oxygen poisoning. 2. Excessive loss of body heat. That free oxygen is a poison was shown by numerous experiments. Even at atmospheric pressure, the animals breathing it show a distinct fall in the amount of carbon dioxid and water excreted by the lungs and a fall of rectal temperature. At several atmospheres pressure the toxic action becomes very marked. The symptoms are pneumonia and convulsions. Thus a mouse placed in one and a half atmospheres of pure, O_2 died of pneumonia in sixty hours, the entire lung being hepatized. At six atmospheres pressure death occurred in two hours, being preceded by violent epileptiform convulsions, and the lungs at autopsy were found to be studded with patches of pneumonia. Below three and a half atmospheres no convulsions were noticed, and at pressures above six atmospheres they were replaced by a comatose state, soon followed by death. These experiments were conducted on a number of animals, and it was found that the larger the animal the less prone it was to the toxic action of oxygen.

That oxygen poisoning is a factor to be considered in compressed air was shown by the fact that the carbon dioxid excretion is depressed and that pneumonia frequently occurs in animals subjected to it. A cat in eight atmospheres pressure of air died in twenty-four hours, its lungs being pneumonic. No convulsions, however, were observed, and it was pointed out that pneumonia could only seldom occur in divers as a result of air pressure, as sufficiently high pressure was not employed in ordinary work, and when employed, as in deep sea diving, the shifts were sufficiently short to avoid danger. The second cause of death, excessive loss of body heat, was shown to depend on the increased heat conductivity of compressed air *per se*, and on the fact that it is saturated with moisture. The enormous influence of this factor, i. e., the cooling effect of wet air, was demonstrated as well by another series of experiments on mice. If these be placed in an atmosphere of water-saturated air, the body temperature soon falls to that of the chamber, the carbon dioxid excretion showing a corresponding fall. A detailed account of experiments is given in the current volume of the *Journal of Hygiene* (Cambridge, England).

The Clinical Side of Caisson Disease.

The next paper was read by DR. CHAS. ALDRICH on "Caisson Disease, from the Clinical Standpoint." After a summary of the history of the disease, Dr. Aldrich cited a number of cases, discussed the symptomatology, and commented on the value of the various precautions taken in caisson work to prevent injury to the workmen.

DISCUSSION.

DR. FRANK ROTH, who had spend eight months on the Cleveland crib as physician, and had done special work on the clinical side of caisson disease, stated that of hundreds of men, both experienced and inexperienced, not one showed any symptoms while in the compressed air, all these being delayed until the change to the normal pressure. The temperature varied in the tunnel according to the temperature of the contained air, but within narrow limits. On locking out there was a slight fall, especially noted in the new men, never to a point below 97. The pulse was usually slowed on entrance into the compressed air, but when work began it reached normal or above. On exit, however, there was in many of the men a very marked change. The pulse of these men, who were for the most part new to the work, became rapid, soft and almost imperceptible, the old hands in the majority of cases showing no marked change beyond an increase in the frequency. Those in whom these changes were most apparent were the ones to suffer most from the "bends."

The respirations increased in rate and depth, and most of the experienced hands had a greater or less degree of chronic emphysema. On locking out there was a sense of faintness and dizziness, the respirations becoming hurried, making the men fairly gasp for breath. This only occurred when the locking-out process was rapid. Dr. Roth stated that there was a great variety in the pains and other symptoms experienced, some of them very evanescent, the others of longer duration. The typical pains were at first fleeting, later localized, usually in the epiphysis of the long bones, with a boring and throbbing character, synchronous with the pulse, which becomes hard and rapid. There is at this point a rise of one or two degrees of temperature.

The more evanescent symptoms, disappearing in the course of a few minutes or half an hour, are also varied. Vertigo, fainting, headache, persistent vomiting, and even complete blindness are not uncommon. Some cases showed deficiencies in the surface circulation, at times associated with loss of reflexes, in others there was a temporary hemiplegia, paraplegia or monoplegia. This paraplegia sometimes came on later as the pains faded away. Severe pains in the epigastrium were noted, and in fat men in the larger muscles, of comparatively brief duration in both cases. Ten cases of a measly hyperemic rash, of half an hour duration, were noted.

Of greatest interest, perhaps, were three cases in which interstitial emphysema was noted. One of these was under the fascia lata, one in the gluteal region, and one in the calf of the leg. In another case gas emboli were seen in one of the veins of the wrist. These bubbles were four in number and were brought together by pressure, remaining visible for twenty minutes.

In some cases hyperesthesia was present for some time after the subsidence of other symptoms. One man fell in a typical epileptic fit after locking out, and denied any personal or family history of that disease.

The form known as the "chokes" appeared in groups of cases and appeared to be more frequent in the mason's shift, when the air was filled with dry cement. Attacks of this were often precipitated by smoking. Emetics gave prompt relief, and it was Dr. Roth's opinion that the attacks were due to a spasm of the glottis.

In the four deaths which occurred all were of the cerebral variety. In the 133 cases observed 68 per cent. had the pains alone, the other 32 per cent. being fairly divided among the other varieties.

The mules were at first locked out with the men, but it was found that this resulted in a mortality of at least one a day, and the experiment was tried of keeping them constantly at the high pressure. This was very successful, nine mules being kept under pressure for nine weeks, and then gradually locked out, the process taking 48 hours. None of these showed any inconvenience, eating twice as much and seeming much more lively than when in the open air. It was noted, however, that in spite of the amount eaten they grew steadily thinner. On the other hand, a horse which had been kept under pressure for almost a year and was then locked out in a very few minutes died at once. Animals frequently urinated and defecated during the process of locking in.

DR. W. T. HOWARD, JR., stated that in the autopsies which he had performed on cases of "bends," there was gaseous emphysema of varying degree, with bubbles in the brain and cord. He also stated that he had found definite hemorrhages on section of these tissues.

NEW YORK ACADEMY OF MEDICINE.

Regular Meeting, held Dec. 3, 1903.

The President, Dr. Andrew H. Smith, in the Chair.

The Cleaning of a Great City and the Handling of Its Waste.

DR. JOHN M. WOODBURY, commissioner of street cleaning, gave the members of the New York Academy of Medicine an interesting talk on this subject, illustrating it with many lantern slides. He said that while large sections of the

boroughs of Brooklyn and the Bronx were swept by means of mechanical sweepers, these machines could not be used in streets having heavy traffic. In the crowded streets the work could only be done by individuals of the street-cleaning brigade. The French had learned long ago that the only effective way to remove the gum and dirt from asphalt streets was by washing with hose, and in certain sections of this city that method was employed when the temperature of the air was above 45 F. The work could be more rapidly and effectively done by using wagons provided with a tank of compressed air and a portable plant for compressing the air. It is difficult, however, to prevent the scattering of dust.

The old method of dumping the city refuse out in the sea was abandoned last March, and consequently the nearby seaside resorts are no longer made unpleasant and unsanitary by the floating in on the shore of all sorts of refuse. The old method cost $300 per week; at the present time, the city rents the privilege of picking over the rubbish as it passes along the belt conveyor, for the sum of $250 per week, with $50 for labor. Moreover, the rubbish which is unsalable is burned under the boilers and produces 250 horse power per hour. It was calculated that by these improvements there had been realized a gain of 400 per cent. on the $20,000 invested in this experimental plant. The garbage is kept separate from the rubbish and ashes and is disposed of by contract to the reduction works on Barren Island. Here it is exposed in digesters to a temperature of 300 F. and to a steam pressure of over 80 pounds, after which it is subjected to hydraulic pressure. The dried sweepings of the streets prove to be a very valuable fertilizing material, for which a ready sale is found. As the ashes are kept free from garbage and rubbish they make good material for filling in land. In this way, he had reclaimed from the borders of Riker's Island no less than 63 acres of land.

Therapeutics.

[Our readers are invited to send favorite prescriptions—such as have been tried and found useful—for publication in these columns. In each case the name of the sender must accompany the prescription, but the name will be published or omitted, as the sender may prefer.]

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Pneumonia.

The following combination is recommended by *Med. Rev. of Reviews* in the treatment of pneumonia in the early stage, occurring in children:

℞.	Potassii citratis	3iss	6
	Spts. etheris nitrosi	3vi	24
	Liq. ammon, acetatis	℥i	30
	Syr. tolutani		
	Aquæ, āā, q. s. ad	℥iv	120

M. Sig.: One dessertspoonful every three hours to a child of three years.

During the stage of expectoration the following combination is recommended for a child of the same age:

℞.	Ammon. carb.	gr. xlviii	3 | 20
	Ammon. iodidi	gr. xxiv	1 | 65
	Syr. tolutani		
	Syr. acaciæ, āā, q. s. ad	℥iii	90

M. Sig.: One teaspoonful every two or three hours.

Inhalations of Formalin.

Spengler, in *Boston Med. and Surg. Jour.*, recommends formalin inhalations in pulmonary tuberculosis and fetid bronchitis prepared after the following formula:

℞.	Formalin	m. lxxv	5
	Alcoholis (absolute)	3v	20
	Spts. etheris	℥iiss	75

M. Sig.: Place ten drops in a tumbler and take ten or twelve deep inspirations, the mouth being removed from the glass to exhale. The first inhalations should be superficial and the latter ones deep. Inhalations are made every other day at bedtime, and stopped after two weeks, to be resumed in a few days and continued as before.

Hemorrhages in Typhoid Fever.

G. A. Sheldon, in *Med. Standard*, recommends the following combinations to control the hemorrhages in typhoid fever:

℞.	Ext. ergotæ flu.	m. x	65
	Morph. sulph.	gr. 1/4	015
	Atropinæ sulph.	gr. 1/150	0004

M Sig.: To be used at one dose hypodermically.

At the same time he administers 15 minims of a solution of adrenalin chlorid (1-1,000), and repeats it in twelve-drop doses every four hours.

As an intestinal antiseptic he recommends sodium sulphocarbolate. After the second week the following combination is given as an antiseptic and to allay as much as possible the tympanitis:

℞.	Olei terebinthinæ	3ii	8 |
	Olei gaultheriæ	gr. xii	| 75
	Pulv. acaciæ	3vi	24 |
	Syr. simplicis	℥iss	45 |
	Aquæ	℥vi	180 |

Misce and filter. Sig.: One dessertspoonful in a little water every four hours.

To remove the sordes from the teeth and to cleanse the mouth the following is used:

℞.	Tinct. myrrhæ	3iss	6
	Glycerini	℥iii	90
	Succi limonis	3i	4
	Aquæ q. s. ad	℥vi	180

M. Sig.: To be used as a mouth wash.

Treatment of Acute Gonorrhea.

In an article in *Chicago Med. Recorder*, F. Kriesel speaks against the irrigation method in the treatment of acute gonorrhea, but in its stead recommends the use of an alkali to render the urine alkaline as an aid in removing the discharge and the attendant toxins. He condemns the use of too strong antiseptic solutions because of the dangers of rendering harm to the mucous membrane. He prefers as antiseptics and astringents, silver nitrate, protargol and ichthargin, used in dilute solutions at short intervals, retained for a few minutes and gradually increased in strength; used at longer intervals and retained for a longer period—for five, ten or fifteen minutes—after the inflammatory symptoms have subsided. During the first few days of the attack the injections should be used during the night also, so as not to lose the good obtained during the day. As much should be injected each time as the urethra will hold. He emphasizes the fact that a gonorrheal discharge will not dry up by using a silver salt as long as the gonococcus is present and not even then, as the silver salt always produces more or less reactive secretion in proportion to its concentration. Therefore, he recommends the use of the microscope to indicate when to give a slight astringent and to discard the gonocide. In general the following outline of treatment may be pursued, according to the author:

During the first two days and nights, injections with protargol ¼ to 1 per cent., or ichthargin one grain to six ounces every two hours, to be retained two minutes. During the next three days protargol, the same solution, every three hours, retained three minutes. The following four days protargol ½ per cent., or ichthargin two grains to six ounces, every four hours, to be retained five minutes. On the tenth day no injection in the morning. The silver salt may then ordinarily be reduced to one injection daily and retained for ten minutes, and as a substitute the following astringent and mild antiseptic may be prescribed:

℞.	Zinci sulphocarb.	gr. v	30 |
	Resorcin	gr. xxx	2 |
	Aq. destil	℥vi	180 |

M. Sig.: Inject three times a day and retain for one or two minutes.

Reserve the silver solution for the time the patient is ready for bed. If at this time no gonococci are present the frequency and strength of the injection may be reduced, giving

only two injections daily and after a short time discontinued. If the secretion reappears with gonococci present return to the treatment of the third week, and if necessary increase the strength of protargol to a 2 per cent. solution or ichthargin ½ of 1 per cent. Stronger solutions of these preparations should never be used, but if they prove ineffective, change off to silver nitrate irrigations of the anterior urethra, which should be done in the following way: Fill a sterile hand syringe with five ounces of a 1-1,000 silver nitrate solution, insert a sterile soft rubber catheter, No. 12 English, well lubricated with sterile glycerin into the anterior urethra and inject through this catheter. Repeat this treatment every other day for a few weeks and give the patient an astringent to use at home.

The following combinations are recommended by *Merck's Archives* in the treatment of gonorrhea:

℞.	Methylene blue	gr. xx	1 | 30
	Copaibæ	℥ii	8 |
	Olei resinæ cubebæ	℥ii	8 |
	Pancreatin	℥i	4 |

M. Ft. cap. No. xxiv. Sig.: Two before each meal; or:

℞.	Largin	℥ii	8 |
	Aquæ destil	℥vii	210 |

Misce, by using boiling water. Sig.: To be used as an injection several times a day; or:

℞.	Largin	gr. xv	1 |
	Glycerini	℥ii	8 |
	Aq. destil	℥vi	180 |

M. Sig.: Inject three times daily for first few weeks, then once daily; or:

℞.	Ichthargin	gr. i-iv	.06-.25
	Glycerini	℥iv	15 |
	Aq. destil. q. s. ad	℥viii	240 |

M. Sig.: Inject four to six times daily.

In cases of gleet and chronic gonorrhea the following:

℞.	Bismuthi subnit.		|
	Mucil. acaciæ, āā	℥iv	15 |
	Aquæ	℥iii	90 |

M. Sig.: Shake well and inject morning and evening; or:

℞.	Methylene blue		|
	Pulv. myristicæ, āā	gr. xl	2 | 65
	Dionin	gr. x	| 65

M. Ft. capsulæ No. xx. Sig.: One capsule three times a day.

Chloroform as a Teniafuge.

In the same periodical, Leger recommends the following, containing chloroform, as an efficacious remedy in the removal of tapeworm:

℞.	Spts. chloroformi	℥i	4 |
	Syrupis	℥i	30 |
	Aquæ	℥iv	120 |

M. Sig.: Two tablespoonfuls to be taken every hour until the entire amount is taken. Before the last dose, a purgative dose of castor oil or tincture of jalap is prescribed.

S. P. Gerhard, in *Med. Record*, recommends, in the removal of tapeworm, a combination of male fern and pelletierine as the most suitable remedy. The patient is instructed to take a good cathartic such as castor oil or salts the day previous to taking the teniafuge. The following morning, as early as possible, a dose of pelletierine tannate, grains 20 (1.30), is taken in two capsules at one dose. When this has operated freely, in about two hours, the following treatment is begun:

℞.	Oleires. aspidii		|
	Spts. etheris, āā	℥ii	8 |
	Hydrarg. chloridi mitis	gr. xii	| 75

M. Ft. cap. No. xvi. Sig.: Two every ten minutes. No food should be taken during this treatment and the worm will be passed in the course of two or three hours.

Toxic Symptoms of Aspirin.

Although aspirin is now very extensively prescribed, the fact should not be overlooked that it may produce toxic symptoms. Dr. Franke, in *Ther. Monat.*, states that after he had taken 15 grains of aspirin to relieve pains in the calves of his legs, within fifteen minutes he noticed marked swelling of the upper lip, which quickly spread over the entire face, followed by difficulty in deglutition, frequent respiration and a pulse rate of 160. These symptoms gradually subsided after twenty minutes, and was succeeded by the appearance of an urticarial rash over the entire body. By the next morning the symptoms had all subsided except the swelling of the lips and eyes. He states that the poisoning was produced by some chemical change in the stomach, phenol being set free and absorbed.

Tuberculous Adenitis.

The treatment of tuberculous adenitis varies with the degree of involvement of the ganglion, according to Broca, in *Med. Press and Cir.* When the ganglion commences to hypertrophy from the infection the treatment should be directed toward the general condition of the patient by the use of iodin, arsenic, iron, phosphate of calcium, together with proper elimination and pure seaside air. A certain number of local remedies are of value, such as cutaneous revulsion, applications of tincture of iodin and interstitial injections of iodin, silver nitrate, zinc chlorid, Fowler's soluton, iodoform and ether and camphorated naphthol.

When suppuration is present curettage should be carried out, and if necessary extirpation of the degenerated glands when fistulæ have formed.

Medicolegal.

Facts Must Be Given with Opinions on Mental Capacity.—The rule that witnesses required to testify to the mental capacity of a person whose sanity is questioned must first state the facts within their observation, on which they rest their conclusions, the Supreme Court of Minnesota holds, in a case of Scott vs. Hay, applies to family physicians who have treated a patient generally for other complaints than his alleged infirmity. It says that the weight of reliable authority sustains this ruling, for, where a personal examination has been made even by a physician or expert, he will be required before giving his conclusion, to describe the symptoms which he observed, to aid the jury in forming a conclusion. Neither medical experts nor other witnesses can be allowed to give an opinion of the mental capacity of a person without first detailing the circumstances and facts on which such opinion is based, and when the opinion of an expert is not based on a hypothetical case, nor on the testimony of other witnesses, but on facts, symptoms and circumstances that have come under his observation as attending physician of the patient or otherwise, such facts, symptoms, or circumstances must be fully stated by the testifying witness, so that the jury can determine whether the facts, as well as the opinion itself, are correct. The court says that the reason for adopting this rule seems to it manifest; otherwise, on a question where symptoms only can furnish evidence of the mental condition of the subject of inquiry, essential elements on which the inquiry is founded would be entirely wanting to aid in the investigation of the question before the court, and the result could be reached only by the number of witnesses on each side, or their respective weight avoirdupois or personal appearance, on a matter where there should be a full investigation of all the conditions which must affect the judgment on a most complicated and difficult subject.

Medical Services for Wife Not Living with Husband.—The Fourth Appellate Division of the Supreme Court of New York says, in the case of Button vs. Weaver, that the husband is liable for actual necessaries furnished to his wife, unless he has made adequate provision for her maintenance, even though they are living separate. As long as the marriage relation continues, the obligation of the husband to support his wife remains. In this case the party sued left his wife—it may be, for the reason which amply justified his departure. She was still his wife, however. He declined to maintain her in his own household, and must make necessary provisions for her elsewhere. The physician suing had previously rendered services to the wife on the faith of the payment by the husband. These services were adjusted by a compromise and payment, and the husband then informed the physician

that he would not be responsible for any further services which the physician might render the wife. The services here sued for were performed after this notification, and the husband urged that circumstance as a reason why he was not liable. This position, the court says, would be impregnable if he had provided suitable medical attendance for her, or given her the means to procure it. A husband living separate from his wife may determine in a large measure in what way his credit is to be pledged, and in what manner the marital duty of providing for his wife is to be fulfilled. If, however, he forbid one from running an account against him for necessaries furnished for his wife in order to make the prohibition effective he must otherwise supply her needs, or permit her to pledge his credit elsewhere. In the present case he directed the physician suing to abstain from performing services concededly necessary for his wife, but made no other provision for her for this necessity. He endeavored to be relieved wholly from the liability resting on him. This he might not do. The physician was entitled to judgment, with interest, besides the costs and disbursements of the action.

Duty to Provide Medical Attendance for Children.—As noted editorially on page 1028 of THE JOURNAL, October 24, 1903, the Court of Appeals of New York has reversed the decision, in the case of People vs. Pierson, reported on page 1464 of THE JOURNAL, May 23, 1903. Involved were the questions of the construction and constitutionality of the provisions of section 288 of the Penal Code of New York providing that "A person who (1) willfully omits, without lawful excuse, to perform a duty, by law imposed on him, to furnish food, clothing, shelter or medical attendance to a minor, ... or (4) neglects, refuses or omits to comply with any provisions of this section, . . . is guilty of a misdemeanor." The court says that it would seem that the legislative intent in adopting this provision of the code is reasonably clear, although possibly more precise language could have been employed. It contemplates that there are persons on whom the law casts a duty of caring for minors, but it does not specify the persons. There are, however, those on whom the duty is "by law imposed." They are designated in the statutes and in the common law as the parents, guardians, or those who by adoption or otherwise have assumed the relation in the place of a parent. The duty of such a person is specified by the provisions of the section. It is to "furnish food, clothing, shelter or medical attendance." Giving the statute a reasonable construction, by applying the rule of necessity, it is apparent that it means the necessary food, clothing, shelter, or medical attendance required for the preservation of the health and life of the child. The court quite agrees that the code does not contemplate the necessity of calling a physician for every trifling complaint with which the child may be afflicted, which in most instances may be overcome by the ordinary household nursing by members of the family; that a reasonable amount of discretion is vested in parents charged with the duty of maintaining and bringing up infant children; and that the standard is at what time would an ordinarily prudent person, solicitous for the welfare of his child and anxious to promote its recovery, deem it necessary to call in the services of a physician. In other words, the court holds that the section, properly construed, means that a person on whom the law has imposed the duty to care for a minor, who willfully omits, without lawful excuse, to furnish such minor with necessary food, clothing, shelter, or medical attendance, is guilty of a misdemeanor. Under this construction of the statute, the duty of parents to furnish medical attendance for their children, the court says, is expressly provided for and is made obligatory on them, even if they were exempt from such duty under the common law. The next question considered was what is meant by the term "medical attendance." Does it mean a regularly licensed physician, or may some other person render "medical attendance"? The conclusion reached is that the medical attendance required by the code is the authorized medical attendance prescribed by the statute; the court stating that this view is strengthened from the fact that the third subdivision of this section of the code requires nurses to report certain conditions of infants under two weeks of age "to a legally qualified practitioner of medicine of the city, town or place where such child is being cared for," thus particularly specifying the kind of a practitioner recognized by the statute as a medical attendant. Nor does the court consider that the provisions of the code are violative of the provisions of the Constitution providing for the free exercise and enjoyment of religious profession and worship, without discrimination or preference, in the state. It says, among other things, that the peace and safety of the state involve the protection of the lives and health of its children, as well as the obedience to its laws. Full and free enjoyment of religious profession and worship is guaranteed, but acts which are not worship are not. The law of nature, as well as the common law, devolves on the parents the duty of caring for their young in sickness and in health, and of doing whatever may be necessary for their care, maintenance, and preservation, including medical attendance, if necessary; and an omission to do this is a public wrong, which the state, under its police powers, may prevent.

2. **Milk in Infant Feeding.**—Park and Holt give their studies in full and sum up their results in a number of conclusions which can be condensed as follows: 1. During the cool weather neither the mortality nor the health of the infants observed were appreciably affected by the kind of milk or number of bacteria contained in it. The different grades of milk vary much less in their bacterial contamination in winter than in summer, the store milk averaging only about 750,000 bacteria per c.c. 2. During the hot weather, the resistance being lowered, the kind of milk influenced both the illness and mortality. Those who took condensed and cheap store milk did the worst. Those who received breast milk, pure bottle milk and modified milk did the best. The effect of contamination was very marked when the milk was taken without heating, but unless excessive it was very slight when heating was applied shortly before feeding. 3. The number of bacteria that may accumulate before the milk becomes noticeably harmful to the average infant in the summer differs with the forms present, the age of the milk and its temperature. When taken raw, the fewer the bacteria the better the results. Of the usual varieties over 1,000,000 bacteria per c.c. are bad for infants, though many infants take such milk without apparent harm. Heat above 170 F. destroys most of the bacteria present, and also some of their poisonous products. No harm from the bacteria previously existing in recently heated milk was noticed in these observations, unless they had amounted to many millions, but in such excessive numbers they were clearly deleterious. 4. When milk of average quality was fed sterilized and raw, those who received milk previously heated did on the average much better in warm weather than those who received it raw. The difference was so marked that there could be no mistake. 5. No special varieties of bacteria were found in unheated milk which seemed to have any special importance in relation to the summer diarrheas of children. The number of varieties was very great and varied according to the locality from which the milk came. None of the 139 varieties selected as most distinct injured very young kittens

when fed in pure cultures. A few cases of indigestion were seen immediately following the use of pasteurized milk more than thirty-six hours old. Samples of such milk were found to contain more than 1,000,000 bacteria per c.c., mostly spore-bearing types. The bad effects produced were not serious or lasting. At present it is rare for milk to be used thirty-six hours after heating. 6. After the first year of life infants are less and less affected by the bacteria in the milk derived from healthy cattle. When the milk had been kept cool the bacteria did not appear to injure children over three years of age at any season of the year unless in great excess. 7. Everything possible should be done by the health boards to improve the character of the general milk supplied, by enforcing proper legal restrictions regarding its transportation, delivery and sale. Such improvements are feasible in our large cities to secure milk which will be wholesome for heating for all classes of the population. The general practice of heating milk, which has become a custom among the tenement population, is undoubtedly a large factor in lessening the infant mortality. 8. The method of a central distributing station has the most advantages since it secures the more constant oversight of the child, and furnishes the food in a form that leaves the mother less to do and avoids most mistakes. This method of feeding deserves to be more extensively employed and might wisely be undertaken by municipalities and continued during the warmer months of the year. 9. The use for infants of milk in sealed bottles should be encouraged when possible. Only the purest milk should be taken raw, especially in the summer. 10. Since intelligent care is most needed, the education of mothers and those caring for infants is important. Properly qualified trained nurses and women physicians visiting the mothers and printed directions are the best means for this purpose. 11. Bad surroundings, though contributing causes, are not the chief factor. The better housing of the poor in the large cities will not of itself greatly reduce the infant mortality. 12. Observations indicate that close percentage modification of milk, though desirable in every case, is not necessary to obtain excellent results in the majority, and that a certain adjustment of the infant to its food is usually soon secured. 13. While it is true that even in the tenements the results with the best bottle-feeding are nearly as good as the average breast-feeding, it is also true that most of the bottle-feeding is so badly done that breast-feeding is infinitely superior and should be encouraged by all means and not discontinued without good and sufficient cause. The matter of expense alone will often favor continued nursing. 14. The injurious effects of table food to infants under a year old, and of fruits to all infants and young children in cities in hot weather should be more generally appreciated.

3. **The Dysentery Bacillus.**—Pilsbury has investigated the question as to the presence of agglutinins for the Shiga bacillus in non-infected persons, and concludes that, while his investigations are only tentative, they warrant the following deductions.

1. The serum of non-dysenteric adult patients does agglutinate the Shiga and acid type (Flexner) bacilli frequently in a 1 to 20 dilution and occasionally in a dilution as high as 1 to 100.
2. This agglutinating power is wanting in the blood of non-dysenteric young infants (under one year) rarely being present even in a 1 to 10 dilution.
3. There are certain differences in agglutinating capability between the Shiga and acid type (Flexner) bacilli, the former in these tests clumping somewhat more readily than the latter.
4. A decided and prompt reaction, under two hours, with the *Bacillus dysenteriæ* in dilutions of 1 to 20 or higher in young subjects (under one year) and in 1 to 50 or higher in older persons who have not recently suffered from chronic or subacute intestinal disease, is probably pathognomonic of acute epidemic dysentery.

5. **Anterior Dislocation of the Shoulder.**—Vaughan recommends in cases of anterior dislocation, which are generally of the subcoracoid variety, the old method of direct reposition. The surgeon places his fingers beneath and to the inner side of the head of the humerus with thumbs on the acromion process, and presses or pulls the head of the bone into place. Extension and counter-extension are also valuable and, he thinks, not appreciated. He applies this method by having the patient lie on the back with a folded sheet in the axilla, the ends extending diagonally across, above and below, the opposite shoulder where they are held by an assistant. The surgeon flexes the forearm on the arm to relax the biceps, takes hold of the arm by both his hands and makes gentle, steady traction, at first in the line of displacement, but as the traction increases, the arm is carried away from the side to an angle of about 45 degrees. The traction is continued just enough to make the muscles tense and an assistant will relieve the surgeon when tired without relaxing the traction. In a short time, from one to six minutes, the confidence of the muscles is gained, the spasmodic contraction ceases, the muscles relax and the head of the bone slips into place. It is doubtful whether this will benefit old cases, but it appeals to him and seems worthy of trial because it is painless and does not require anesthesia; is perfectly safe in recent cases; can be used by the general practitioner who would hesitate to try the more complicated methods; does not injure the tissues, and succeeds in most cases. Kocher's is the next method if the others fail. It consists of three steps: Flex the forearm of the affected side to a right angle with the arm, press the elbow to the side, and rotate the humerus outward by carrying the forearm around until it stands directly out from the side. Still holding the forearm at right angles to the body, bring the elbow forward or forward and slightly inward until the arm is horizontal. If the head of the bone does not slip into place during the second step, make internal rotation by placing the hand on the opposite shoulder and lowering the elbow into position. This method is painful and usually requires anesthesia and may do some damage to the tissues. If all these three methods fail in spite of anesthesia, the dislocation should be reduced by arthrotomy, provided aseptic operation is possible. Vaughan condemns the use of the foot, knee or fist in the axilla on account of the damage to the axillary vessels and nerves. He reports a case.

6. **Diphtheria.**—Zahorsky has studied the mortality statistics of diphtheria with the antitoxin treatment and has obtained data from about a dozen leading physicians in St. Louis who have employed it in their practice with children with surprising results—only 1.5 per cent. mortality in 1,610 cases. This includes the laryngeal cases; many of which were intubated. There are possibly certain errors such as the non-recognition of the disease in time, the use of insufficieint dose of antitoxin, the inefficient character of the serum and mistaken diagnosis, accounting for the occasional deaths. One of the physicians thinks no patient with diphtheria should die. Zahorsky believes the statistics are not singular, but can be duplicated anywhere by physicians who believe in antitoxin and know how to use it.

7 and 8.—See abstracts, THE JOURNAL, November 28, p. 1362.

9. **Vaginal Operations.**—Moffat has been led by his observation of the work of J. Riddle Goffe to employ the vaginal method, and he reports results. He concludes from his own personal experience and study of other cases:

1. The anterior vaginal route is most useful to reach and operate on the round ligaments in cases of retroversion of the uterus or procidentia; also for removal of small fibroids, either subperitoneal or pediculated, or for conservative work on the ovaries and tubes, or for removal of these organs.
2. The posterior incision is most useful for drainage in cases of pyosalpinx, salpingitis, pelvic abscess, some cases of tubal pregnancy with hematocele and puerperal sepsis, either with or without involvement of the tubes; for oöphorosalpingectomy, when the ovary is held backward and downward by old adhesions, and even in some cases of acute general septic peritonitis.

The more I see of this work the more am I impressed with the important truth that no pus tube should be attacked by any other route than by the vagina.

He thinks that hysterectomy is attended with very serious danger in puerperal cases and better results can be obtained by posterior section and removal of the infected tubes and the opening up and draining of pus collections as they may appear. In certain desperate cases this has given him very satis-

factory results. He summarizes the cases treated during the three years in the St. Joseph Hospital.

10. **Inflammation of the Bladder.**—Spooner gives an interesting discussion of the literature as to the causes of bladder inflammation, and illustrates the conditions found. He insists on a guarded prognosis in these cases. As regards tuberculosis he finds that primary tuberculosis is very rare. It generally occurs in complication with tuberculosis of the epididymis or of the prostate and extends by continuity. It is, therefore, more frequent in men than in women and children. The prognosis is always unfavorable.

11. **Sahli's Test-Meal.**—Aronson criticises Sahli's "butter and flour soup" test meal as follows:

1. When made according to Sahli's description, the soup is not homogeneous.
2. The application of the test-meal to general practice is entirely impracticable.
3. The time consumed in determining results is incommensurable with the advantages derived from its use.
4. The lack of agreement in every case between the clinical diagnosis and the diagnosis according to the Sahli method.

15½ Dry Hot Air in the Treatment of Bright's Disease (to be concluded). Clarence Edward Skinner.
16 *The Treatment of Acute and Subacute Anterior Gonorrhea by Retrograde Injections of Stronger Solutions of Silver. (Concluded.) Hermann G. Klotz.
17 A Visit to Naha Hospital. J. A. Guthrie.

13. **Carcinoma of the Breast.**—Massey selects this case on account of its typical character and micro-diagnosis, and also from the fact that recovery seemed to occur from a single application of massive mercuric cataphoresis. There is at present an excellent and healthy scar and the patient's condition is greatly improved. He thinks the method has the advantage over other procedures in the fact that the growth with all infected cells was devitalized at once, without the loss of blood, by a process that made operative reinfection of the wound impossible. Any outlying infected cells for a short distance beyond the area of destruction were also liable to be destroyed by the diffused chemical without detriment to the healthy tissues. The cancer occupying about one-half the breast was also destroyed without the entire sacrifice of the organ.

14. **Femoral Dislocation.**—Soutter and Bradford's article is a study of a special condition of congenital femoral dislocation; that is to say, the femoral twist. The article is too detailed for abstracting.

15. **Tubercular Peritonitis.**—Lobingier discusses the literature of tubercular peritonitis noticing especially its frequency in women which has led to the belief that the appendages may be primarily involved. Even though the evidences of appendiceal tuberculosis may not be marked, it is possible that it may exist as Whitridge Williams has shown. The symptoms are not definite or constant. Kelly regards pain in the back and hypogastrium as the most frequent symptom, though it is absent in many cases. The temperature is never characteristic and a number of other conditions may be simulated. Lobingier thinks that when the history of the patient, progress of the disease, character and location of the pain, tenderness, temperature, pulse, condition of the bowels and the state of nutrition are all carefully considered, it ought to be properly diagnosticated in any of its forms. As regards prognosis, authorities are quoted, and he favors Veit's opinion that while recovery may occur spontaneously, it is not to be counted on, and laparotomy in all but the ulcerative, caseous variety is almost always rewarded by cure or substantial benefit. Failures are due to advanced general infection of other organs. Recent cases should be operated on promptly and chronic ones operated on if spontaneous cure does not seem probable. Veit favors simple section in the linea alba, mopping out the effused fluid, and closure of the wound. When the adnexa are involved they should be removed. He ascribes the cure to the antitoxic action of the serum from the wound.

16. **Gonorrhea.**—Klotz' article is concluded in this issue with reports of cases of different classes. The primary ones he thinks are the most important and convincing, and while he is aware that many prominent specialists are adverse to early local treatment he does not agree with them, but holds that we should remove or destroy the irritant and infecting microbe as early as possible. While no one method will perhaps satisfy in all cases, he regards the method here proposed of retrograde injections of the stronger solutions of silver as worthy of a fair trial.

23 *Mycotic Disease of the Ear Canal: With Report of a New Fungus. S. E. Cook.
24 The Canteen. George M. Kober.

18. **Movable Kidney.**—Aaron holds that 90 per cent. of the patients who suffer from movable kidney and associated ptoses can be relieved without operation. Of the 442 cases here summarized, 321 were females and 121 males, ranging in age from 8 to 70. The right kidney was movable in 194 cases, the left in 20. In 228 both were adrift. Only 2 patients had Dietl's crises, and these were referred to the surgeon for operation. In 9, previous operations had been without results. In 215 cases there has been absolute recovery; 168 patients were improved and 59 have been either not improved or passed out of sight. The method which he advocates is the use of bandages to hold in their proper place the displaced organs. They should be constructed for each patient out of stiff material and should fit accurately. If the intestines are in position care must be taken that the hand does not press on them, or harm may follow. It is a good plan to inflate the colon, which is apt to be prolapsed. The position of the stomach, spleen and liver must be ascertained. He is in the habit of making a mould of the abdomen with a piece of lead so as to get the exact shape of the patient just at the lower edge of the displaced kidney, where the greatest pressure must come. There should be no pressure on the kidney itself or on the upper part of the abdomen. Ready-made bands are generally failures, and it sometimes takes a number of trials to get just the right appliance. Operations have not given as good results as his method. Besides properly supporting the kidney and other displacements, diet, tonics, electricity and massage are a help in the treatment. Seven cases are briefly reported.

19. **Typhoid Fever.**—Fairbairn insists on the proper definition of typhoid fever as being based on the presence of the Eberth-Gaffky bacillus.

20. **Houston's Valves.**—Martin reports a number of cases of valvular obstipation treated by valvotomy. He points out the symptoms of hypertrophy of the rectal valves as inability to properly defecate and the acquirement of the "physic habit" with periods of constipation interrupted by short periods of diarrhea, which may later be more frequent and finally be the predominant condition. Ultimately symptoms of intestinal obstruction may become pronounced, and if relief is not afforded, the case may end fatally. The symptoms of pain, aching in the iliac region, backache and sciatica, hemorrhage, catarrhal or membranous proctocolitis, prolapse, hemorrhoids, fistula, etc., may be signs or complications of the obstructing valve. Of the 40 patients here reported, 2 were not improved and 5 were improved, 3 of these with complications; 33 were cured. He says it should be recognized that valvular obstipation may recur, even after operation, by the development of hypertrophy in valves not previously subject to the disorder. The patient should be advised in case of a period of two or three days without defecation to use saline laxatives, glycerin and water enemata at a temperature of 120 F., remaining in bed for a day or two, at no time lying on the back, but to

keep the hips elevated, and then come to the physician who can directly massage the rectal valves through the proctoscope with a cotton-guarded forceps and spray the mucosa with a weak solution of nitrate of silver.

23. **Mycotic Disease of the Ear Canal.**—In the case reported by Cook a fungus was found, identified by Dr. Pound of the University of Nebraska, with the *Sterigmatocystis candida*, a species hitherto unknown or not reported as existing in the human ear canal. In these parasitic cases the prognosis is usually good, but relapses are frequent. The treatment should be directed to the restoration of the tissues to the normal condition by removal of the processes or fungus. Water should be used sparingly. Powders are better, but alcohol is an exception to other fluids, as it rapidly penetrates the crevices of the skin and cools the inflamed surfaces by its rapid evaporation. It should be used somewhat diluted. About 2 per cent. of salicylic acid will increase its utility. Burnett claims that a powder of one part of chinolin salicylate and 8 to 16 parts of boric acid will destroy the fungus as well as the micro-organisms of suppuration. Following the destruction and removal of the fungus and the products of inflammatory reaction, use in case of severe inflammation a solution of 20 minims of subacetate of lead; 6 minims of dilute acetic acid; 20 minims of opium sedative solution and 1 ounce of distilled water. Instil 10 drops, warmed, into ear canal, as directed. His own plan is after cleansing out the ear to use a dilute solution of alcohol, 60 to 80 per cent.

Boston Medical and Surgical Journal.

28 A Case of Sarcoma of the Lower Jaw. F. B. Lund.
29 Chronic Cyanosis from Acetanilid Poisoning. J. N. Hall and H. R. McGraw.

25. **Hypernephroma.**—This form of renal tumor occurs encapsulated in the kidney substance or just below the kidney capsule, usually in the adult male. It interferes with function by destruction of the renal substance or by compression or both together. Its growth is rapid and usually malignant, though it may be benign in some instances. It usually involves the renal vein and sometimes the vena cava, and metastases are formed along the blood current, especially in the lungs, liver and bones, but they do not involve the lymphatic channels. Three cases are reported by the authors, with postmortems, which illustrate the characteristic points of both the gross and microscopic pathology of these growths. An affected kidney may not be much increased in size, but is generally large. The general outline of the organ is usually retained and the surface is always nodular. On section the tumor tissue is generally yellowish, with a firm and distinct stroma. Some of these nodules show areas of hemorrhage and degeneration.

26. **Accessory Thyroids.**—Six cases, one previously reported, are here given by Low and he discusses the literature. He remarks on the rarity of metastases, the tendency to rapid recurrence and the necessity for supposing that there is a metaplasia of the cuboidal into the cylinder cells in the growth. In the treatment the fact that these tumors show a certain malignancy should be borne in mind. They should be thoroughly and completely removed if possible without incising the capsule surrounding the growth, great care being taken to prevent scattering in the wound bits of tissue which may become the germs of recurrence. The operation is generally difficult, and when incomplete there is almost always recurrence.

27. **Appendicitis.**—Two cases of appendicitis are reported, one in which there were found to be pin worms present, and in another a lumbricoid worm was discovered half way through a perforation. He concludes that intestinal parasites cause appendicitis by their action as a foreign body. Possibly their struggles may bring about a perforation where otherwise none would have occurred. Trichocephalus dispar has been proved to cause an inflammation of the appendix by injuring the mucous membrane while sucking the blood of the host. Ascaris has been found with a material similar to that in trichocephalus in its intestinal epithelium and, therefore, is supposed to attach itself to the mucosa of the host, and thus start appendiceal inflammation. As regards *Oxyuris vermicularis*, there is no proof that it causes appendicitis other than through its action as a foreign body.

32 Surgery of Prostate, Pancreas, Diaphragm, Spleen and Thyroid. (Continued.) B. Merrill Ricketts.

31. **Typhoid Gangrene of the Limbs.**—Ricketts' article is concluded in this issue with a study of the cases from the literature and report of a case in his own observation. His conclusions are given as follows:

1. Sudden pain in extremities at any time during typhoid bad omen.
2. Nearer Poupart's ligament the more dangerous.
3. Pain does not always indicate location of clot.
4. Clot most frequently in popliteal artery.
5. Rapid progressive gangrene beginning at toes indicates occlusion of aorta, iliac or femoral artery in Scarpa's triangle.
6. Slow progressive gangrene indicates occlusion of vessels from below upwards, especially in early stage.
7. Line of demarcation forms sooner during convalescence, but femoral or even the iliac may be occluded; even when it forms in lower leg may not form for six months.
8. Partial occlusion of vessel may occur during attack or convalescence with recovery, but complete occlusion may become gradual and gangrene take place one year later, as in Estlander's case.
9. The want of collateral circulation may be due to anomalous circulation.
10. Partial occlusion of one or more vessels may occur without gangrene, even though sensibility be impaired.

Cocain used subcutaneously or by blocking the nerve trunk may become an important factor in amputating extremities during typhoid fever.

41 Tubular Pregnancy. W. E. Anderson.

35. **Malarial Neuroses.**—James calls attention to the complications produced by malaria in pregnancy especially in inducing false labor pains. He also comments on cases in which the bladder becomes irritable from malarial poisoning, producing frequent and painful micturition which is relieved by arsenic and quinin. This trouble, he thinks, is quite common. Druggists treat many cases empirically by methylene blue and often hit the mark. Other organs that may be affected by malaria are the stomach, producing nausea more or less continuous, pain and dyspeptic symptoms and intestinal trouble. It may cause decided profuse diarrhea or even dysentery. He gives illustrations of several of these conditions, especially the false labor pains which are not apparently uncommon in cases in his part of Southern Virginia.

42.—See abstract in The Journal of October 24, p. 1040.

43. **Pulmonary Gangrene.**—McArthur reports 3 cases operated on, 2 successfully; that is to say, the patients recovered. He says that since under medical treatment 80 per cent. of the patients die, and only 29 per cent. of those operated on, surgical intervention is the appropriate treatment. While it is anatomically possible to separate the pleura from the chest

wall, it is difficult and often futile, and we should not lose much valuable time attempting it. A circular suture combined with gauze pressure packing for forty-eight hours is the best means of inducing adhesions. The *x*-ray may give valuable aid in the localization. Great care, however, should be taken in the selection of cases, but when the gangrene is localized and single, the most desperate cases should be given a chance, as they frequently recover with drainage.

44. **Varices and Varicose Ulcers.**—Rodman advocates the method of circumferential incision. The incision is made at the junction of the lower and middle third of the thigh, at about the triangular junction of the flexors. Preferably here, on account of the advantages as avoiding tension and the greater ease in dissecting out the veins. This incision avoids the external saphenous vein which, though often implicated, is never culpable. He says make the incision slowly and carefully in order not to endanger the veins and to avoid cutting one or two large nerves of the skin. Carry it down to the aponeurosis or fascia. Dissect and ligate the veins above and below the incision and excise between the ligatures. Apply dry dressings. Flex the knee and bandage the limb to the hip. Elevate the foot of the bed. Keep the patient confined one week, then let him walk on crutches; keep him out-doors with a bandage to protect the cicatrix and to support and regulate the circulation. Keep on the bandage for four weeks. The omission of the bandage compromises the integrity of the scar, and edema occurs that ought to be avoided.

51 *The Release of Quarantine in Diphtheria. Thomas W. Salmon.
52 *What Is the Limit of Safety Where More Than One Operation Is Indicated? Albert Vander Veer.

51. **Quarantine in Diphtheria.**—From a study of 100 cases with special reference to the time of quarantine, Salmon concludes that the severity of the disease bears no relation to the duration of the infection and an arbitrary time-limit is not justifiable. The occurrence of positive cultures after a single negative one had been obtained is shown to be the rule, rather than the exception. The importance of taking cultures from nose as well as the throat in the pharyngeal cases is demonstrated by a number of instances included in the series in which the nose remained infected longer than the throat. He advises two negative cultures be taken on alternate days from both the nose and throat after two weeks have elapsed from the onset of the disease, a requirement which is not unfair to any, though permitting the release of only about 6 per cent. of the infected persons.

70 *On the Use of Opium in the Carditis of Children. Alexander Morrison.
71 *Infantile Colic. Alexander McAllister.
72 *Constipation in Infants and Young Children. W. J. Fenton.

70. **Opium in the Carditis of Children.**—Morrison pleads for palliative remedies as life-savers in cardiac inflammations in children, and the value of opium properly used in these cases. The younger the patient the greater the care in its use, but even young children when excited locally and generally by an actively irritative process, can tolerate larger doses than under normal circumstances. He quotes cases at length, showing the tolerance of children for considerable doses of morphin. While the personal case he relates resulted fatally the relief it gave was marked and the results of postmortem examination revealed the anatomical conditions underlying the symptoms. In combating carditis he feels disposed to give permanent place to opium.

71. **Infantile Colic.**—The dangers of the rubber nipple, especially those with a long tube, are emphasized by McAllister, who would never use any nipple continuously over two weeks. He insists on having two, one being kept in an alkaline cleansing wash, while the other is being used. The dangers of too rapid feeding are pointed out, and he remarks on the necessity of careful physical examination as to the cause of the colic. In the treatment too careful circumspection in the use of drugs can not be practiced. Many cases can be permanently relieved by a little manipulation with or without gentle massage of the abdomen. Next to this is warmth applied to the abdomen, dry or moist, or internally in the form of sips of hot water, or hot enemas. In spite of all efforts, however, some infants require medication with carminatives. In these cases the standard teas frequently prove too weak. Paragoric with opium excluded is a remedy of considerable value. The dose is easily regulated, beginning with a few drops. He quotes Rotch as advising the use of carminatives between feedings, and gives one of his favorite prescriptions. It consists of 40 grs. of sodium bicarbonate; 40 minims of aromatic spirits of ammonia; 30 minims of glycerin and 2 ounces of peppermint water. One teaspoonful to be given between feedings. When acidity is not an element requiring special treatment, asafetida is frequently of value. The use of narcotics is only exceptionally permissible.

72. **Constipation in Infants.**—The causes and treatment of constipation are reviewed by Fenton. In the majority of cases it depends on an excess of proteid and deficiency of fat in the diet. He notes that boiling and pasteurizing seem to affect the milk for infant feeding. He quotes Starr that carefully standardized laboratory milk is also liable to produce intestinal disorders and malnutrition in some cases, domestic modification of milk being freer from these dangers. In hand-fed children constipation is much more frequent and often difficult of treatment. Starchy food may be given too early and there may be a general depression of the health from other causes, such as want of fresh air or habitual use of enemata, while remedies

injudiciously given for colic may be the cause. Want of a sufficient quantity of fluid drunk may be the cause. The constipation may disclose a serious nervous disorder. He insists on a quiet, regular life for the nursing mother with sufficient rest at night, plain nourishing diet, etc. The composition of the milk varies at different times. Regularity in the infant's feeding is of importance. If medicinal treatment is also necessary, fluid magnesia, a few grains of carbonate of magnesia, manna, or an occasional dose of castor oil may be given. A small suppository of glycerin or the domestic remedy of a small cone of soap, inserted into the rectum, is useful and efficacious. It is wise to trust to the natural appetite of hand-fed infants where vomiting is absent and the food is given regularly. Sometimes the milk should be stopped and whey broth, meat juice, albumin water or a thin dextrinized gruel be substituted. Frequently, partial or complete peptonization suffices. A teaspoonful of fine oatmeal made into a paste and stirred into the morning milk is sometimes useful. The common cause of constipation in infants being excessive proteid and deficient fat, these defects must be met by a suitable addition of cream. Massage is a valuable remedy. For drugs he mentions in the simple cases a teaspoonful of manna dissolved in hot water or a few grains of phosphate of soda, either of which may be added to the milk, and usually prove sufficient. Fluid magnesia, or ½ to 1 grain of sulphur may be given. For co-existing colic and flatulence some mild cathartic is employed. The aim is to get the bowels freely open first and then keep them open by the use of drugs as little stimulating as possible. In older children regular habits should be encouraged. Enemata are of service if fecal masses have collected in the rectum, but their use should not be persisted in.

74 A Clinical Contribution to Traumatic Enophthalmus. Dr. Purtscher.
75 The So-called Embolism of the Central Artery of the Retina and of Its Branches. Max Reimar.

73. **Glaucoma.**—The long prevalent theory of increased tension as the cause of glaucoma is combated by Wahlfors. It is true that increased tension exists in the acute, inflammatory type of disease, but in the simple form it is absent. He does not, however, consider the two types as distinct. The real origin of the trouble he thinks is in atrophy of the choroidal elements. This destroys the nerve sensory apparatus and leads to increase of tension by paralysis of the muscular network of the choroid, slowing the course of the currents of liquid. The channels of exit thus become blocked and cause retention. It is here and not in the uveal region that the cause of increased tension is to be found. Excavation may occur without an increase in the tension, as it is liable in simple glaucoma where there is no increase of tension. He ascribes excavation to atrophy of the connective tissue composing the framework of the lamina cribrosa and the diminished resistance of the papillary tissues. Atrophy is probably primary and excavation secondary. As regards treatment he thinks that there is little that can be done for the processes in simple glaucoma excepting by repeated injections of strychnin, which in a certain proportion of his cases have been beneficial. By giving these injections one a day for ten or twenty days, repeated three or four times a year, he has been able to preserve vision for many years. In acute glaucoma iridectomy is of value as it prevents venous stasis—the last link in the chain of congestive glaucoma. It may also be of prophylactic value in simple glaucoma as preventing acute exacerbations.

82 The Element of Anemia in Diseases of Women. Everett S. Hicks.

76. **Tubercular Glands and Life Insurance.**—Eisendrath has studied the literature and statistics of the subject. From these as well as his own observation he concludes that tubercular glands of various regions are frequently followed by foci, mostly of the lungs (28 per cent). Next in frequency are the bones and joints. Operative treatment gives the best number of permanent recoveries (54 to 80 per cent.). Every insurance examiner should keep in mind the above figures and investigate carefully as to the possibilities of a late focus following tuberculous adenitis in early life.

77. **Intermittent Albuminuria.**—Whitridge discusses the subject and reviews the opinions of various authorities on the question. He thinks that a mere trace of albumin in the urine does not justify the turning down of an applicant for life insurance, but he should be kept under observation and repeated examinations made. In all cases it is important to know the amount of urine passed daily. If there is no history of frequent micturition, if the urine is of normal specific gravity and the urea normal, he thinks the applicant is insurable.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures, single case reports and trials of new drugs and artificial foods are omitted unless of exceptional general interest.

British Medical Journal, London.

November 28.

1 *The Treatment of Some Acute Visceral Inflammations. D. B. Lees.
2 Syphilitic Joint Disease. E. Percy Paton.
3. The Spread of Ankylostomiasis. T. H. Hendley.
4. A Case of Abdominal Hysterectomy for Retroperitoneal Cervical Fibroid. Arthur H. N. Lewers.
5 Two Cases of Retroperitoneal Cysts: One Causing Obstructive Jaundice and the Other Simulating an Ovarian Cyst. Charles A. Morton.
6 Retroperitoneal Manipulation—A Method of Separating Deep-seated, Plastic, Pericecal or Other Peritoneal Adhesions. G. Gore Gillon.
7 *Subperitoneal Lipomata. John Campbell.
8 *The Treatment of Visceral Papilloma by Injections. Herbert T. Herring.
9 Case of External Urethrotomy Treated by Continuous Retention of a Rubber Catheter Held in Position by a "Perineal Stop." C. Hamilton Whiteford.
10 The Pathology of Hallux Rigidus. J. M. Cotterill.
11 *Further Notes on Leishman's Bodies. Ronald Ross.
12 *The Etiology of One of the Heterogenous Fevers of India. C. Donovan.

1. **Pneumonia.**—Lees' second lecture is on pneumonia. He says that when the vitality is feeble or other viscera are damaged or there are old pleural adhesions, when the lungs are fibroid or emphysematous, or the patient is chronically poisoned by alcohol, tobacco or sepsis chance for recovery is small. Pneumonia kills, he says, by a paralyzing overdistension of the right heart on which the toxin seems particularly to act, as particularly distinguished from that of rheumatism which affects the left heart. Most important in treatment is constantly to watch the right heart, preventing overdistention by timely removal of a small quantity of blood, a precaution too often neglected, which fact he thinks is responsible for a large part of the mortality. The procedure should be repeated when necessary. The diet should be such as can be taken without effort and easily assimilated. Milk meets these indications and acts also as a diuretic, thus helping to carry off the toxins. We have to consider, however, that an increased amount of fluid increases the amount passing through the right heart, and he would, therefore, only give small quantities of predigested and highly nutritious elements during the intenser stages of the disease when this cardiac complication is marked. He suggests one-half ounce of sodium and potassium bicarbonate, dissolved in 2 ounces of malted milk every hour for an adult; for a child, two teaspoonfuls in an ounce. After the leech has relieved the heart it is possible to give considerable quantities of water. During the first two or three days he would give milk alone in quantities of two to three pints a day, but not later. Sleep must be obtained, and if pain demands it morphin may be necessary. Even at a late stage or in severe cases morphin may sometimes be safely given if the right heart has been relieved and the air passages cleared by venesection an hour or two previously. But if the right heart has been duly relieved by leeches and local applications of the icebag made over inflamed areas, morphin is rarely necessary unless the pleura is seriously involved. He thinks strychnin is the most useful cardiac tonic; this should be given subcutaneously in dose of ½ to 1 minim of the official solution, B. P., twice daily, in the beginning with a child; and in the adult 2 minims morning and evening at first, increasing to as much as 5 minims if necessary. Atropin by subcutaneous injection is often useful, especially in children; in adults belladonna is less convenient. Oxygen by inhalation assists aeration of the blood and improves the quality of the blood supply to the heart. It is a true cardiac tonic, but neither strychnin or oxygen will save the patient if the right heart is allowed to become paralyzed. Digitalis is most likely to be of service after the cardiac symptoms are relieved and the fever is moderate. Ammonium carbonate may be given when there is much secretion in the bronchial tubes and repeated small doses of alcohol may be of service, but large quantities are likely to do more harm than good. It is absurd to think that brandy can support the heart when the right side has become paralyzed from overdistension. Ice applications over inflamed areas are of great value, and must be used much more freely than in pericarditis. Lees suggests also that such applications lessen the proliferation of bacteria and quotes Dr. Neave, who has investigated on this point. From Washbourn's experiments he concludes that lung consolidation and pyrexia are largely due to the local effects of an albumose produced by the growth of the pneumococcus.

7. **Subperitoneal Lipomata.**—Campbell reports two cases, one of the malignant and one of the benign variety. Subperitoneal lipomata are much more frequent in women than in men—a ratio of 25 to 16, and are more frequent on the right side. The malignant variety includes retroperitoneal tumors which originate on the posterior aspect of the abdomen, difficult and almost impossible to remove, microscopically, sarcomatous in whole or in part. Those affected are at first in good health, but ultimately waste while the tumor increases. The benign variety includes lipomata of the broad ligament, omentum and appendices epiploicæ. These tumors can be safely removed. They do not cause much general deterioration of the health.

8. **Vesical Papilloma.**—Three cases are reported by Herring, who thinks they demonstrate the following facts:

1. Recurrence of papilloma after removal by suprapubic cystotomy, which, unfortunately, is very frequent, may be effectually held in check by injections of silver nitrate. 2. If injections are made, when it has been found impossible to remove the growth entirely by operation, the recurrence of the symptoms is retarded longer than could be expected without the treatment. 3. Much of a tumor may be removed by the urethra without serious hemorrhage, and a result gained equal in some cases to that of a suprapubic operation. 4. There is reason to hope that papillomatous growths may be entirely destroyed by long-continued applications of silver nitrate.

The conclusions, therefore, that may be drawn, although confirmatory evidence is needed, are: (*a*) Injections should be made after operations for the removal of the growth, whether the operator is satisfied that he has done so efficiently or not. (*b*) The urethral route should be tried, when removal of the papilloma is contemplated, before a more serious operation is undertaken.

The question whether most cases of papilloma should be operated on through the urethra before the injections are commenced, even when the diagnosis is made early and the tumor is small, or whether injections alone should be relied on, requires further investigation. I should be inclined under favorable circumstances to give the former plan another trial; for, in the first place, the operation need not be severe nor attended with serious consequences, if strict attention is paid to sterility in instrumentation; in the second, the improved instruments recently made by Leiter and the advantages derived from adrenalin in stopping hemorrhage, render manipulation more certain; and thirdly, the size of the tumor to be attacked by the injection afterwards will be less even if only small portions are removed, and consequently the time required to check the disease shortened. In the female I have no doubt that this is the proper proceeding. Suprapubic cystotomy can hardly ever be wanted when access to the bladder is more easily gained through the urethra by the means of Kelly's tubes.

11. **Leishman's Bodies.**—Ross concludes that these bodies belong to a new genus of sporozoa and that the individual bodies are spores produced in the matrices, which would appear to be relics of the parent organism. He has no scientific name to offer for the new genus, but suggests "Leishmania." If such were adopted the species would be "Leishmania donovani," as Laveran has used the name "Piroplasma donovani."

12. **Leishman's Bodies.**—Donovan briefly reports that he finds these bodies in the spleen of patients suffering from an irregular fever, with enlarged spleen and liver, paroxysmal edema of the feet, congestion of the lungs, occasional subcutaneous hemorrhages and cancrum oris. He thinks they probably are the causal factor. Medication by quinin, arsenic and sodium salicylate has proved ineffectual.

The Lancet, London.

November 28.

13 *The Administration of Chloroform to Man and to the Higher Animals. Augustus D. Waller.
14 The Present State of the Irish Poor-law Medical Service. R. F. Tobin.
15 Some Questions in Seaside Climatology. Alfred F. Street.
16 Patent Medicines. Robert Hutchison.

17 On Albuminuria as an Accompaniment of Diabetes Mellitus. (To be continued.) F. W. Pavy.
18 Fracture of the Fifth Cervical Vertebra; Recovery. W. E. F. Tinley and A. R. Jones.
19 A Confirmatory Test for the Presence of Meconic Acid. F. N. Windsor.
20 A Case of Teratoma of the Neck. F. Bolton Carter.
21 Note on a Dicephalous Monster. Alexander M. Elliot.
22 Remarkable Transposition of the Viscera. John C. Thomson.

13. **Chloroform.**—Waller insists on the importance of accurate dosage of chloroform in anesthesia; this can be obtained by Dubois' pump. Chloroform vapor should be maintained under 1 or 2 per cent. of the inspired air. He relates experiments showing the use of this method; 5 per cent. is dangerous, between 1 and 2 per cent. is the safest. Rule of thumb methods are not accurate or safe.

Journal of Tropical Medicine, London.

November 16.

23 *Calabar Swellings on the Upper Congo. Patrick Manson.
24 *Goundou: Its Relation to Yaws. A. Neli.
25 The Effect of Drainage and Other Measures on the Malaria of Klang, Federated Malay States. (To be continued.) Malcolm Watson.
26 Municipal Sewerage. (Continued.) Fred. Smith.

23. **Calabar Swellings.**—Manson reports a case in a missionary on the Congo. The disorder known under this name consists of attacks of edematous swellings of certain parts of the body with pain and loss of power. As the cases are found in association with the *Filaria loa* and appear to be especially prevalent in the area of its distribution, the conjecture that they are caused by this nematode seems not unreasonable. It occurred to him that these swellings might be provoked by the discharge into the connective tissues of embryos by a parental loa. From the connective tissue they may find their way along the lymphatics into the general circulation where their life may be limited. He thinks an examination of the blood soon after the appearance of a Calabar swelling might disclose an embryo. It seems to be a disease which specially affects males; only one woman, as far as he has known, has been attacked among the missionaries on the Congo.

24. **Goundou.**—Nell concludes that yaws bears a causal relation to goundou, which consists in symmetrical osteomata on the nasal processes of the superior maxillary bones, always congenital, either apparent at birth or to be detected on close examination. The general enlargement is always concomitant with body growth and stops with full adult life. An acute enlargement or an attack of yaws follows. Some congenital cases are not noticeable if no acute enlargement has occurred, and adults with slight ridges or bosses should be questioned regarding goundou or yaws in the family.

Australasian Medical Gazette, Sydney.

October 20.

27 Mechanism of the Paroxysmal Neuroses. Francis Hare.
28 Management of Epidemic Plague. J. Ashburton Thompson.
29 A Case of Aneurism of the Transverse Aorta. Louis Henry.
30 On Certain Pelvic and Abdominal Operations. E. T. Thring.
31 Gastric Surgery. R. Humphrey Marten.
32 Notes on Gastric Surgery. W. Anstey Giles.

Intercolonial Medical Journal of Australasia, Melbourne.

October 20.

33 Movable Kidney. G. Rothwell Adam.
34 The Surgical Aspect of Floating Kidney. H. Critchley Hinder.
35 Movable Kidney in Woman. J. A. G. Hamilton.
36 Cases of Arthritis Resembling Acute Rheumatism. G. R. Baldwin.
37 Post-nasal Growths: A Criticism and a Comparison. W. Kent Hughes.
38 Case of Malignant Disease of Face Treated by Plastic Operation. W. Moore.
39 Good Result Following Extraction of Lenses for High Myopia. James W. Barrett and W. F. Orr.

Bulletin de l'Académie de Médecine, Paris.

40 (LXVII, No. 36.) Transmission des maladies parasitaires du sang par les Tabaniens (horse flies). P. Mégnin.
41 A propos de la maladie du sommeil (sleeping sickness). Discussion.
42 Potable Water in Garrisons. Discussion.
43 (No. 37.) *La nature syphilitique et la curabilité du tabes et de la paralysie générale. Leredde.
44 Address at Inauguration of Monument to Charcot. Raymond.
45 *Antituberculosis Serum and Vaccine. A. Marmorek.

43. **Curability of Tabes and General Paralysis.**—Leredde proclaims that tabes and general paralysis are curable when antisyphilitic treatment is commenced in time with adequate dosage. He believes that it is possible to inject a healthy subject with .035 gm. of metallic mercury daily, that is, twenty times the usual dosage of Panas' biniodized oil. Inunctions are uncertain and unreliable.

45. **Marmorek's Antituberculosis Serum and Vaccine.**—Marmorek's communication read before the Académie November 17 is not published in the *Bulletin*, only the title being given, A detailed report of it was embodied in an editorial in our last issue. [Our Italian exchanges comment that the principle of the antitoxic serum and the technic of its production are identical with those of Maragliano's serum which has been in constant use for eight years and which has abundantly established its efficacy in appropriate cases. Maragliano's annual reports have been chronicled in THE JOURNAL from year to year. Marmorek's article is published in full in the *Archives Gen. de Médecine* of November 24, No. 47.—ED.]

Presse Médicale, Paris.

46 (II, No. 90.) *La circulation du liquide céphalo-rachidien. F. Cathelin.
47 (No. 91.) Exérèse du trijumeau (of the trigeminal). L. Ramonède.
48 Hydro-Dilator for Treatment of Stricture and Dilatation of Cervix. P. Bakaleinik (Kiev).—Traitement des rétrécissements de l'urètre, de l'esophage, de l'anus. Dilatation du col utérin. Instrument illustrated.
49 (No. 92.) L' enseignement technique à la clinique ophthalmique de l'Hotel-Dieu. F. de Lapersonne.
50 Atherome aortique expérimental par injections répétées d'adrénaline dans les veines. O. Josué.
51 Traitement chirurgical de l'occlusion intestinale aigue. L. Braun.

46. **Circulation of Cerebrospinal Fluid.**—Cathelin announces that we can accept as established a circulation in the cerebrospinal fluid similar to that of the lymph. It issues from the blood and returns to it through the intermediation of the lymph circulation. He describes with diagrams the mechanism as he has traced it out.

Revue de Gynécologie, Paris.

Last indexed page 1171.

52 (VII, No. 5.) Les kystes racémeux de l'ovaire. F. Jayle and X. Bender.
53 Etude anatomique et pathogénique des kystes hématiques primitifs de l'ovaire. F. Potier.
54 *Traitement opératoire de l'exstrophie de la vessie. Transplantation des urétères par le procédé de Maydl. E. Orloff (Charkov).
55 De l'occlusion au niveau de l'angle colique gauche (at left angle of colon). H. Morestin.
56 Traitement des abcès pelviens d'origine appendiculaire en particulier par l'incision rectale. L. Bérard and Patel (Lyons).

54. **Operations Performed to Date for Exstrophy of Bladder.**—Orloff includes in his comprehensive monograph all cases he has been able to find in which Maydl's method of transplanting the ureters has been followed or more or less modified. It forms an array of 61 cases including 5 from his own experience. Three of his patients did not long survive the operation. The results were excellent in the 2 others. He also reviews other operative methods with their results to date.

Semaine Médicale, Paris.

57 (XXIII, No. 46.) *Multiplicité et complexité des produits solubles développés au cours d'une infection. Charrin.
58 Letter from America. F. Munch.—L'exercice de la médecine aux Etats-Unis.
59 Les courants de haute fréquence dans le traitement de la méralgie paresthétique. H. Bordier.
60 La photothérapie des adénites et des arthrites tuberculeuses. Bellemanière.

62 (No. 47.) *La dilatation forcée du sphincter anal comme moyen de traitement de l'entérocolite muco-membraneuse. A. Roussel.
63 Letter from America. Le corps médical aux Etats-Unis. F. Munch.

57. **Products Elaborated During Infections.**— Charrin has for years been conducting experimental researches with the *Bacillus pyocyaneus*, as reported from time to time in these columns. Reviewing his own work and that of others he remarks that two principal characteristics mark the progress of medical science in late years: 1, the realization of the fact that most of the symptoms and changes that develop in the course of infections are due to the action of toxins, a multiple

and complex intoxication. Some of the toxins proceed directly from the bacteria, others indirectly from their action, either from the changes induced in the humors or tissues by the direct action of the germs or their secretions and excretions or from the reactions of the cells and organs under the influence of these elements. This mechanism of intoxication may proceed from the interior or exterior; it may be organic or inorganic, of bacterial or cellular origin. In other words, the same as in actual poisonings or autointoxications, the toxic compounds preside over the genesis of the infectious or diathetic accidents. The second characteristic of recent progress is the growing importance accorded to the organism itself, the *rôle de l'économie*, as Charrin calls it, in the genesis of pathologic conditions. We have already partially restored the "soil" to its old predominant place in the etiology of disease. We recognize the predisposition afforded by getting chilled, over-exertion, inanition, etc., and the organism is coming into its own in this respect more and more every day. For instance, in very young infants the disturbances consecutive to chronic gastro-enteritis are due in certain cases to the insufficiency of the intestinal defenses. During the acute stage the numbers or the virulence of the poisons engendered in the digestive tract are responsible for the symptoms observed, but in many cases, after this stage is past, the poisons are found to be no more active than those elaborated in the normal infantile intestine. Their peculiarly deleterious action is due to the lack of protection against them. The direct or indirect action of the tissues and of the physiologic apparatus in the mechanism of morbid phenomena is becoming more manifest every day. Cellular pathology is resuming its rights, not altogether Virchow's old cellular pathology, but a conception singularly enlarged. The idea that a microbe engenders disease by the aid of its toxin is being shown up more and more to be altogether too limited and inadequate to conform to what we are learning in regard to the multiplicity and complexity of the soluble products elaborated during the course of an infection by the interaction of bacteria and the cells of the organism. Immunity is only a special phase of nutrition, the consequence of these interactions.

62. **Dilatation of Anus as Cure for Enterocolitis.**—Roussel had occasion five years ago to treat a woman of 40 for both fissure of the anus and mucomembranous enterocolitis. He proceeded to the forcible dilatation of the anal sphincter for the first trouble and found to his surprise that the second was also favorably influenced and soon healed. He has since treated 4 other cases of mucomembranous enterocolitis alone by forcible dilatation of the sphincter, and in each case the results of this intervention have been equally satisfactory. One of the patients had two relapses, once during pregnancy and again during lactation, and in another patient the stools occasionally show a tendency to the mucomembranous form, but it is speedily dissipated by a little castor oil and oil injections. He attributes the success of the measure in these case to the action of the dilatation in arousing the contractility of the atonic colon and banishing the spasmodic contraction of the lower part of the intestine. He prefers the fingers to any instrument for the dilatation, and afterward inserts a wick in the rectum, expelled with the first discharge. Any tendency to constipation afterward is easily corrected by the ordinary drugs, previously ineffectual.

73 *Experimental Research on Action of Local Stimulation and Local Application of Heat. Wessely (Berlin).—Zur Kenntnis der Wirkung lokaler Reize und lokaler Wärmeapplikation (nach Experimenten am Auge).
74 Zur Aetiologie der Blasen-Ektopie. Enderlen (Marburg).

64. **Pseudo-Leukemia and Allied Affections.**—Pappenheim summarizes his views in the statement that multiple myeloma and malignant lymphoma as well as the spleen affection, pseudo-leukemic splenomegaly, are merely various manifestations of one and the same process, a hyperplastic-lymphosarcomatous process—pseudo-leukemia.

66. **Goiter Fistula.**—Payr has had occasion to observe 4 cases of perforating strumitis. He reports the details, with cuts, and reviews 36 similar cases which he has found in the literature. Treatment can be only the extirpation of the fistulous tract and part of the gland involved. This operative intervention is rather difficult but is imperative on account of the dangerous complications liable to set in at any moment.

67. **Perineal Cystotomy.**—By a transverse incision of the perineum followed by detachment of the rectum, the bladder is freely exposed without the interposition of urethra, etc. Frank has operated on the bladder in 3 cases by this method and has found it superior to others, as he details at length.

68. **Dangers of Raising the Pelvis.**—Kraske's communication has previously been referred to in THE JOURNAL as it was presented at the German Congress of Surgery. He reports 2 fatalities which he ascribes to the Trendelenburg position. In one case the heart was degenerated and the distension of the organ and high pressure of the blood in the inferior vena cava entailed acute and irreparable dilatation of the heart. The conditions noted in the second fatal case demonstrate that it may be dangerous to raise the pelvis in obese subjects, especially those with very fat omentum, mesentery and appendices epiploicæ, as these factors favor displacement of the intestines and consequent occlusion. Pressure against the liver may induce congestion in the portal vein and congestion and hemorrhage in the stomach lining. Postoperative gastric hematemesis may be due to this cause. He advises shortening or avoiding altogether the Trendelenburg position in operating on very corpulent subjects, suggesting that its effects should be counteracted afterward by raising the other end of the trunk as soon as possible, and avoiding the use of all constricting bandages.

70. **Tuberculosis of Posterior Segments of Spine.**—Wieting presents a careful study of 14 cases of this affection and 89 he has collected in the literature. He practices in Turkey.

72. **Complete Perforation of Chest from Side to Side by Broom Handle.**—The case described was one that caused much comment at the German Congress of Surgery. A woman fell from a step-ladder on a broom handle which entered at one axilla and emerged at the other, but without breaking the skin at the latter point. There was traumatic pneumothorax, also extensive subcutaneous emphysema which acted as a safety valve for the air accumulating in the thorax. The various organs in the chest had been pushed aside without injury. When seen five and one-half hours after the accident, each axilla was tamponed tight and constricting bandages applied. The air was soon absorbed and recovery was prompt and complete with no signs of infection.

73. **Local Irritations and Application of Heat.**—Wessely's experiments have convinced him that local application of heat attracts the immune bodies to the points where they are needed to defend against invasion of microbes. His interesting experiments were made on rabbits' eyes.

Beiträge zur klin. Chirurgie, Tübingen.

75 (XXXIX, No. 3.) *Zur akuten Osteomyelitis im Gebiete des Hüftgelenks (in hip). B. Honsell (Tübingen).

76 *Beitrag zu den extrakraniellen Aneurysmen der Carotis interna. C. Blauel (ibid).
77 *Ueber primäre Tuberkulose der quergestreiften Muskeln (of striated muscles). E. Zeller (ibid).
78 *Resultate der Exstirpation des tuberkulösen Sehnen-Scheiden-Hygroms der Hand. B. Zöppritz (ibid).
79 *Retropharyngeal Tumors. H. Hellendall (Strasburg).—Ueber retropharyngeale Geschwülste.
80 *Treatment of Fractures of Patella and Remote Results. G. Schmidt (Breslau).—Entstehung und Behandlung der Kniescheibenbrüche mit besonderer Berücksichtigung der Dauererfolge.
81 *Zur Diagnose und Therapie der Kleinhirnabszesse (cerebellar abscesses). W. Lossen (Carlsruhe).

75. **Acute Osteomyelitis in Hip.**—In early childhood this process is liable to be comparatively benign. Later in life the severer cases, with suppuration of the joint, should be treated by amply exposing and resecting the parts. Under other conditions conservative treatment is generally indicated. Including the moderately severe and the milder cases, the record in the Tübingen clinic is now 121 cases with a mortality of 14 per cent. Twelve died without any operative intervention, and 3 of the fatal cases had been treated by resection and 2 by exarticulation. The *x*-ray is the most useful aid for diagnosing the condition and its consequences, as Honsell demonstrates by numerous examples and an anatomic study of the parts involved. Recovery was complete in 89, including 38 with ankylosis, 29 with spontaneous luxation and 21 with detachment of the epiphysis. Resection was done in only 19 and exarticulation in 2 cases. Total mortality, 14 per cent.

76. **Extracranial Aneurism of Carotid.**—The patient was a woman 58 years old who had suffered for ten years from an aneurism of the internal carotid. Sudden rupture causing a false aneurism entailed severe symptoms of dyspnea, neuralgia, etc., requiring tracheotomy. The rapid increase in size of the tumor imposed further operation and the common carotid was ligated and the aneurism extirpated, with complete success.

77. **Primary Tuberculosis of Striated Muscles.**—Zeller reports 2 new cases.

78. **Tuberculous Hygromata.**—Zöppritz states that 35 cases of tuberculous hygroma in a tendon sheath on the hand have been treated by extirpation of the cyst at the Tübingen clinic. All but 14 were male subjects, and the majority were between 20 and 40 years old. The remote results in 31 cases are known; three-fourths of the patients have been completely cured during the years that have elapsed since, up to fifteen in some instances. The functional results were perfect in 11 cases and nearly perfect in 13. Recurrence was observed in 9, and 4 of the patients have succumbed to an intercurrent disease.

79. **Retropharyngeal Tumors.**—Hellendall's experience with extrapharyngeal operations has been more favorable than with the intrapharyngeal; the subsequent infection and mortality are much less with the former. He reviews 31 cases, including 23 treated by radical intervention, and confirms the assertions of others in regard to the almost exclusively connective-tissue nature of these tumors. Out of 27 examined under the microscope, only 2 were of epithelial nature and only 10 benign tumors. His article discusses the subject from various points of view, symptoms, course, location, etc.

80. **Fractures of Patella.**—Fifty-two cases of fracture of the patella have been observed at Breslau. In 31 cases the patella was sutured, while 17 were treated by massage alone. The fracture may be due to contusion or laceration, and the latter particularly requires suture as it prevents extravasation, interposition of soft parts and canting of the fragments, while it insures firm union and permits early movements of the joint. In case of a recent fracture the incision is made across, but in old cases the parts are incised lengthwise. With a recent fracture it is deemed best sometimes to suture with aluminum bronze wire the parapatellar lacerations. As a general rule, however, no suture is attempted unless asepsis is reasonably certain. Schmidt reviews the particulars of the entire series.

81. **Diagnosis and Treatment of Abscess in Cerebellum.**—Eight out of 10 cases of cerebellar abscess have been operated on at Carlsruhe by von Beck, and three have been permanently cured by the intervention. The cause of the abscess was invariably a chronic suppuration in the ear. In 8 cases there was a cholesteatoma of the tympanum, in 2 inflammatory or suppurative mastoiditis. In 6 cases the abscess was on the left side and in 1 it was bilateral. It must be opened at once and an accompanying meningitis is not an absolute contraindication unless too extensive. Prompt operation is imperative even on a presumptive diagnosis, at least opening up the sinus and dura, with exploratory puncture and incision. Beck's technic is described in detail, with brief notes on the various cases.

82. **Etiology of Dysentery.**—Jürgens denies that dysentery can be due to a single variety of bacilli and describes an epidemic of 26 cases of severe dysentery which occurred in a certain regiment during the August military maneuvers in West Prussia. He cultivated from the stools in 19 cases a bacillus resembling that of Flexner's and agglutinating with a Flexner animal serum. It differed in several respects from the Kruse-Shiga and other bacteria. The serum of the patients agglutinated the isolated bacilli.

84. **Asepsis in Catheterization and Cystoscopy.**—Casper recommends a mixture of glycerin, water and tragacanth with 1/500 mercury oxycyanate as an ideal lubricant for catheters and sounds. It is similar to the lubricants proposed by Guyon and Kraus, but has the advantage that it does not irritate the urethra, renders the instruments extraordinarily smooth and slippery, is rapidly soluble in water and dissolves as soon as the instrument is inserted in the bladder, without obscuring the view through the cystoscope. It can be kept in paint tubes, ready for use at any moment. For rinsing out the bladder he has discarded boric acid, etc., in favor of mercury oxycyanate, 1/5000, as it is limpid, does not irritate the tissues or injure the instruments and although not a strong antiseptic yet has power to inhibit the growth of microbes. He sterilizes the cystoscope and catheter by mechanically rubbing all the parts with three gauze sponges dipped in tincture of soap, using each a minute in turn. The instrument is then wrapped in a compress impregnated with tincture of soap and left in it until needed. The removable parts are boiled for five minutes.

85. **Ivory Radius.**—A little girl fell on her arm and caries developed in the radius with almost complete destruction of the diaphysis. It shelled out as a sequester and was substi-

tuted by an ivory rod fitting into the epiphysis at each end. The child goes to school and plays like other children, using her hand as before. Only active pronation and supination are a little difficult or restricted, otherwise the hand functions perfectly. Radiograms a year later show considerable proliferation from the retained periosteum and epiphyses, and the slight functional disturbances have all subsided. Vogel remarks that the experiment has thus been crowned with perfect success, and whether the ivory rod is absorbed or expelled later or tolerated as a foreign body is immaterial so far as the success of the intervention is concerned.

87. **Iodism.**—Lesser explains iodism as the effect of the iodized alkalies suddenly flooding the organism and pouring out through the mucous membranes. This afflux of alkali causes a catarrhal condition in the mucosæ which is the cause of the iodin intoxication. He suggests in prophylaxis that the iodin salts should be administered in a mucilaginous vehicle to render absorption slower and more gradual. Also that the daily quantum should be fractioned into as many doses as possible. It may be advisable sometimes to administer the iodid per rectum, which also retards absorption. Another prophylactic measure is to use the iodin in the form of iodized fats or by injections of iodipin. It might be possible to commence with small injections of iodipin to accustom the organism gradually to the action of a moderate circulation of iodin, in cases of very pronounced idiosyncrasy against it, and then gradually substitute internal administration.

89. **Sterilization of Silk by Diffusion Currents.**—Ahlfeld and Vahle announced as long ago as 1896 that alcohol and water have no disinfecting power alone, but when one is added to an article impregnated with the other, the diffusion causes currents in and around the bacteria which kill staphylococci in two minutes. Ausin has been applying this suggestion to the sterilization of silk. He first boils it in alcohol to remove all fat, impurities, etc. It is then set aside to dry and before an operation it is boiled in water for twenty minutes, then placed for five minutes in alcohol, then for five minutes in water and again boiled in alcohol for twenty minutes. He has not had a single stitch abscess or mishap of any kind since he has been using silk thus prepared.

92. **"Occult" Blood in Feces Sign of Gastric Ulcer.**—Boas is much surprised that more attention has not been paid to his previous announcements of the pathognomonic importance of minute quantities of blood in the stomach content or feces as a sign of some ulcerative lesion in the stomach lining. (See THE JOURNAL of September 20, 1902, p. 726, abstract 42.) These occult bleedings have just as much importance as pronounced hematemesis or melena, and will frequently decide a dubious diagnosis long before any physical signs of a tumor are present. This is especially the case when due attention is paid to the familiar sensitive point in the epigastrium and the other painful point in the back, near the left, twelfth dorsal vertebra, to which he has called attention. It is a simpler matter to detect this occult blood in the feces than in the stomach content, as the introduction of the stomach sound is liable to cause a slight erosion which might bleed and thus lead to erroneous deductions. Minimal amounts of blood can be readily detected in the feces with the sensitive guaiacum test, which has revealed blood in the feces after ingestion of even as small an amount as 3 c.c. Boas mentions as an instance of the delicacy of the test that in a case in which a gastric ulcer was suspected, no blood was found in the feces on repeated investigation until one day and then it was learned that the patient's gum had bled very slightly while the teeth were being brushed. Every precaution must be taken to exclude raw or partly cooked blood from the diet for two days before the test, and also to insure soft stools with Carlsbad salts or something of the kind. Menstruation, hemorrhoids, etc., must also be excluded. The occult bleeding was frequently noted when the subjects had recently complained of pains in the stomach. This was particularly the case when the patient was not on an "ulcer diet." On the other hand, after restricting the patient to a strict milk diet for several days it was usually impossible to detect any blood in the feces. When the blood persisted in the feces on a milk diet, the assumption was strongly in favor of carcinoma developing on the basis of an ulcer. The blood findings may vary from day to day and consequently repeated investigation is necessary. Boas has had his presumptive diagnosis of an ulcer confirmed by these occult blood findings in 25 cases. It has proved still more valuable, however, in the cases in which the diagnosis and consequently the justification for treatment wavered between a purely nervous cardialgia and ulcerative processes in the mucous lining of the stomach or duodenum. His doubts have been banished in many instances of this kind and appropriate treatment successfully instituted solely on the basis of the determination of these occult bleedings. They require the same critical judgment as more copious hemorrhages and, in fact, may be merely the preliminary to the latter. These occult bleedings will be found very valuable from a therapeutic point of view, as by their aid we are able to trace the results of treatment, to learn whether bismuth, silver nitrate, etc., actually improve the morbid conditions to the extent anticipated. They have already established beyond question the great value of a strict milk diet for the healing of ulcerative processes in the stomach. On such a diet the occult bleeding ceases and blood can no longer be detected in the feces, even after resumption of a mixed diet. The softer consistency of the milk may have something to do with the benefits derived, and further studies in this line are urgently needed. Boas thinks that it is impossible to treat an ulcus subject as an out-patient. The duration of treatment varies in the practice of different physicians from two to six weeks. With the aid of the occult blood we will be able to establish an individual term of treatment in each case dismissing the patient as soon as repeated tests fail to disclose further occult bleeding for several days in succession. The technic of the tests is very simple. About 20 c.c. of ether are added to .5 to 1 gm. of soft or softened stools. This removes the fats and prevents disturbing emulsions later. About 3 to 5 c.c. of glacial acetic acid are then added to the feces and the whole is poured into a test tube and extracted again with ether. There must be no admixture of alcohol as this disturbs the test. As guaiacum dissolves readily in ether it is not necessary to use the tincture. A few grains of finely pulverized guaiacum resin are added to the ether extract, the whole is carefully shaken and then 20 to 30 drops of oil of turpentine are added. The whole is shaken up again and then set aside. The color gradually changes to a violet or blue, rendered still more intense by addition of chloroform. This blue tint is sometimes masked by the brownish color of the fluid and the findings of the test can be controlled by repeating it with Klunge's aloin test. As much aloin as can be taken up on the tip of a small spatula is placed in a test-tube and lightly shaken up with 3 to 5 c.c. of 60 to 70 per cent. alcohol. The acetic-acid and ether extract of the feces or stomach content, prepared as above described, is treated with 20 to 30 drops of turpentine and then immediately afterward with 10 to 15 drops of the freshly prepared aloin solution. In the presence of blood the fluid rapidly assumes a bright red color which turns to a fairly durable cherry red as it stands. If there is no blood the fluid remains yellow for an hour or so and then becomes a light pink. The color changes may be hastened by adding a few drops of chloroform. Boas makes a practice of conducting the two tests as controls, and believes that the aloin is superior in several points to the guaiacum. It is not influenced by the presence of fats or fatty acids and is sometimes positive when the guaiacum findings are dubious. Only once in his experience was there a pronounced guaiacum reaction with no aloin response. A still further modification of the technic is the substitution of dilute hydrogen dioxid for the oil of turpentine. In both the tests the response is just as characteristic with the addition of 25 to 30 drops of this fluid as with the turpentine.

93. **Prophylaxis of Gastric Cancer.**—Katz comments on the rarity of cancer in that part of the digestive tract in which the chyme is of a soft consistency. He thinks that gastric cancer would become less frequent if the diet were restricted

more to soft foods as free as possible from solid substances. He urges that more attention should be paid to thorough mastication, to the use of soft foods and to copious ingestion of fluids while solid foods are being eaten. He believes that by approximating the conditions in the stomach to those which obtain in the duodenum, cancer in the stomach will become as much of a rarity as cancer of the small intestine.

102. **Treatment of Sarcoma of Long Bones.**—Vogel advocates resection instead of amputation or exarticulation in the treatment of sarcomata of the shafts of the long bones. In the case described the humerus was affected, with extensive involvement of the soft parts. The bone was resected its entire length except for the lower 3 cm. Recovery was smooth and the patient has been in good health—no signs of recurrence—during the four years since.

104. **Survival of Epidermis Flaps.**—Wentscher's latest series of experiments include the preservation of Thiersch flaps for seven to fourteen days in a test tube plugged with cotton. The flap was then transplanted on an exposed muscle, that is, on a tissue free from epithelial elements. In two out of the four experiments, unmistakable evidences of proliferation and regeneration were noted, with considerable mitosis. One of the experiments was negative, and in the fourth no mitosis could be detected.

105. **Foreign Bodies in Male Bladder.**—Hirsch reports 8 cases observed in his service at Vienna and tabulates the details of 103 other cases published in the literature since 1856. In 2 of his 8 cases the foreign body was extracted instrumentally. In only 4 out of the total 111 cases was the foreign body spontaneously evacuated. Rona managed to expel a piece of a catheter in the bladder by stroking it downward through the rectum. The foreign body was extracted by aspiration in 3 cases.

109. **Tuberculosis of Cranial Bones.**—Wieting reports 10 cases observed in Turkey. Six of the patients were children between 3 and 10 and the others between 14 and 40. The prognosis depends on the absence or presence of tuberculous lesions elsewhere. When primary, the affection is usually cured by radical ablation of the focus.

110. **Claudius' Iodized Catgut.**—Martina has followed Claudius' method of preparing catgut in 70 cases, and healing was by primary intention in all but two, and in these cases the suture was above reproach. No untoward symptoms from the use of the iodin were observed in any instance. It evidently enhances the strength of the catgut, but this effect is transient. After five or six days the threads become so loose that the catgut can not be safely used for suturing the skin, muscles or fascia, and hence can not be used in herniotomies. Its chief field of usefulness is for ligatures, especially in operations on goiters and in amputations. He omits the rinsing in carbolic solution which Claudius regards as indispensable. Experimental tests of the iodized catgut are described, all confirming the above statements.

112. **Acute Pancreatitis.**—Pels-Leusden had occasion to treat 2 patients who exhibited symptoms of peritonitis accompanied by violent vomiting and extreme heart weakness. The abdominal cavity was opened and the pancreas region merely drained with a strip of iodoform gauze as patches of fatty necrosis were discovered in the pancreas and, in one case, a large amount of a yellowish slightly turbid exudate was found in the abdominal cavity. The vomiting ceased at once after the operation and the patients promptly recovered. They were both women, one 21, the other 53 years old The writer is convinced that abdominal fatty tissue necrosis is invariably due to an affection in the pancreas accompanied by stagnation of the secretions in the organ.

114. **Osteomalacia Chronica Deformans Hypertrophica.**—The right tibia was involved in the case described by Schmieden, the patient a woman of 58. The bone was very much enlarged with curvature and with brown pigmented patches on the skin. After amputation it was found that the bone substance was so soft it could be indented with the fingernail. The microscope showed that the normal bone tissue had been destroyed, and that there was very little new bone formation, with almost entire absence of lime salts. A wedge of the tibia was resected at first, with rapid healing. Later, part of the knee was removed, the wound suppurating interminably until the patient begged for amputation, which freed her once and for all from her affection, which had lasted for three years.

116. **Skull Plastics.**—Kayser believes in reimplanting the bone fragments in case of traumatic defects in the skull, whenever such a course is practical. Pieces of the inner table are especially favorable for the procedure as they can be readily fitted into place and owing to their smooth inner surface do not induce formation of adhesions. The application of the fragments to close the defect must immediately follow the injury. The fragments of the inner table should be turned to fit them into place in the cancellated tissue between the tables. By this fixation all danger of pressure on the brain from any loose sequestra is prevented, as also prolapse of the brain. Secondary plastic operations are not interfered with, while it is thus possible to close the gap in the skull at once, even in case of injury of the protecting membranes and of the brain itself. In a case thus treated there was a depression in the skull, 7 by 5 cm., and 1.5 cm. deep, in the posterior half of the left parietal bone. The bone was cracked and broken into a number of pieces, the brain substance below much injured. After the fragments had been removed, the wound cleansed and hemorrhage arrested by tamponing, two of the large pieces of the inner table were reimplanted in the defect, turning them around so the longer diameter of the bones bridged the shorter diameter of the gap. No narcosis was necessary and all the symptoms gradually subsided so that the young man now considers himself well. The inner table always fractures more extensively than the outer one in such injuries, and is peculiarly adapted for autoplastics in these cases.

120. **Embolic Gangrene.**—The prompt recovery after amputation of both thighs in the case reported should encourage others to resort to operation in time. The patient was a man of 41 and the gangrene developed suddenly a week after an

attack of grippal endocarditis. The case indicates that the presence of numerous bacteria in the blood does not contraindicate amputation. The stumps should be merely tamponed at first. In a second fatal case described the gangrene developed after typhoid, and the slow, gradual course suggested thrombosis, but an embolus was found in the right iliac artery and another in the left hypogastric, with an embolic thrombus at the bifurcation of the aorta.

122. **Joint Mice.**—Boerner devotes 54 pages to a clinical and pathologic-anatomic study of loose bodies in the joints, profusely illustrated. Thirty-five cases are described in detail. He rejects the assumption of an inflammatory origin.

141 How to Live in Egypt. E. Fromherz.—Wie kann man in Aegypten leben?

123. **Psychiatry and Experimental Psychology in Germany.**—Weygandt describes tests of the memory, attention, etc., conducted on mentally affected and on healthy subjects and shows the great value of the results for psychiatry. He also reviews similar research published by other German writers. Among the facts brought out is the rapid and pronounced disturbance in the perceptive faculties entailed by paraldehyd—a fact which explains its prompt sedative action. Tests of the memory before and after an injection of morphin showed that the subject's capacity to memorize unconnected syllables diminished nearly if not quite one-half after the morphin. A still more pronounced reduction in the memorizing tests was observed on subjects purposely kept awake, and also during fasting. He thinks that the results already obtained show the necessity for a laboratory for experimental psychology in every psychiatric clinic, in charge of trained assistants.

126. **Hyperhidrosis Universalis.**—Gillet has reported a case of hyperhidrosis universalis occurring at the periods of suppressed menses and ceasing as soon as menstruation was normally resumed. This is the only case Müller has been able to find resembling at all the one he here describes. His patient was a trained nurse, who, after a strenuous winter's work, noted hyperhidrosis universalis at the time of the menses, ceasing during the intervals, finally supplanting the menses completely, and becoming continous. In six months she lost 40 pounds and became very weak, suffering besides from eczema caused by the constant sweating. The symptoms indicated exaggerated oxidation processes, and Müller explains them as the reaction of the organism to excessive functioning of the sweat centers, with the consequent great loss of warmth. The affection was probably a manifestation of neurasthenia. No treatment was effectual and the patient succumbed about eighteen months after the first symptoms had been observed. Postmortem examination was not allowed, and there is a possibility that the trouble may have been due to some brain tumor.

129. **Familial Amaurotic Idiocy.**—Mülberger relates that in a well-to-do German family, free from morbid taint of any kind, the two children are both typical specimens of familial amaurotic idiocy only that the eye findings differ a little from those hitherto recorded. The gray atrophy of the optic nerve was the first morbid process observed, and to date is the only one in the eyes of the younger child, while the other presents already the typical appearance in the region of the macula.

132. **Functional Kidney Tests.**—This communication issues from Helferich's clinic at Kiel and tabulates the findings in 7 cases of kidney trouble in which the functional tests were applied. In spite of their failings it is impossible to dispense with these tests, Göbell exclaims, but he proceeds to prove that certain preliminaries are indispensable. In the first place the patient should be put on a certain standard test diet for several days before the tests are applied. It is important, further, that the urine should be drawn at a certain interval after the meals and that the catheters should be left in the ureters for two or three hours in order that the urine corresponding to certain divisions of time may be examined. The amount of urine and its molecular concentration should both be determined during these separate periods. These points must be regarded, as a surgically affected kidney does not do its work regularly but rather spasmodically, and also because the proportions between the freezing-point and the molecular concentration of the urine from both kidneys vary during the different periods. A still further reason is the fact that the relation between the freezing-point of the urine from each kidney does not correctly represent their functional activity. In 2 of his cases the findings of the functional tests at first would have led to erroneous deductions if they had not been controlled and rectified by repetition of the tests two or three times. The composite findings of three or four tests afforded data confirmed by the operation and its results, as he shows in a comprehensive table.

133. **Ether Drop Narcosis in Gynecology.**—Fuchs extols the superiority of the ether-drop method of narcosis, especially for gynecology. Chloroform will in future maintain its place as an occasional adjuvant, especially in laparotomies, and also as an indispensable aid in obstetrics. In 300 cases in which he has used the morphin-ether drop narcosis he has had no cases of asphyxia or noticeable cyanosis and only 2 of febrile bronchial catarrh, both consecutive to a laparotomy. Chronic bronchitis is no contraindication to ether. The slightly increased expectoration after the narcosis is rather an advantage than the reverse.

134. **Ether Narcosis.**—Hofmann states the ideals of modern narcosis as the freest possible intake of atmospheric air and the smallest amount of ether, supplemented if necessary by some other substance. He also lauds the ether drop method among other reasons for its simple technic which does not require the painstaking care needed for chloroform.

135. **Ether-Drop Narcosis in Combination with Morphin-Scopolamin Injections.**—Hartog is assistant at Landau's clinic and reports very gratifying experiences with the narcosis indicated in the title. He reduced the dose very materially below those recommended by the author of the latter method, injecting subcutaneously only .5 mgm. of scopolamin and 1 cg. morphin at another point thirty minutes to an hour before the operation. In 93 cases in which this technic was followed there were none of the inconveniences of the usual narcosis, no vomiting nor agitation, etc.

136. **Morphin-Scopolamin Narcosis.**—Korff is the originator of this method and announces that a few unfavorable experiences reported by others impelled him to seek the minimum doses possible to induce narcosis. He gives the particulars of 50 important operations done under his modified technic. He does not use it on patients under 16 nor over 60 years of age, but in all other cases applies it without reserve. He has found that equally good results are attained when only .001 gm. scopolamin hydrobromate is used and .25 gm. morphin in 10 gm. distilled water. He injects one-third of a Pravaz syringe two and a half hours before the operation, another third one and a half hours, and the other third half an hour before.

THE CAUSES OF THE OCCASIONAL FAILURE OF OPERATION TO CURE GALLSTONE DISEASE.*

WILLIAM J. MAYO, A.M., M.D.
Surgeon to St. Mary's Hospital.
ROCHESTER, MINN.

Surgery of the gall bladder and bile passages is one of the most satisfactory branches of our art. The death rate, taking the cases as they come, is hardly more than 5 per cent., and in uncomplicated cases less than 2 per cent., the result depending to a large extent on the condition of the patient. Including all causes of failure to cure, either complete or partial, and such late sequelæ as adhesions and hernia, the number of such instances is small. In 631 operations on the gall bladder and bile passages we had but 19 cases, or about 3 per cent., which required a secondary operation. During this period, however, we have on a number of occasions operated a second time for symptoms arising after an operation performed elsewhere. It is fair, therefore, to presume that some of our cases have, unknown to us, been operated on at a later period by other surgeons, and that failures to establish a complete cure have been more numerous than this percentage would seem to indicate. It must be taken into consideration also that many patients have symptoms referable to uncured lesions, which are not sufficiently serious to demand operation, and these may be accounted as partial or temporary failures; but looked at even in this light, gallstone surgery is signally successful, and practically all of the patients are benefited, and few would exchange their post-operative for their previous condition. Lack of experience and poor methods made incomplete operations relatively more frequent in our early work. At the present time the accumulated knowledge of the profession has given a technic which is gradually enabling the surgeon to avoid errors and to overcome those causes which lead to subsequent troubles. Of course, in rare instances, the condition of the patient may not warrant a complete procedure at one sitting, and a two-stage operation is deliberately elected.

With a single exception, to be referred to later, all of the cases in which results were less perfect than were desirable, occurred in complicated cases, and it can be laid down as an axiom that delay in seeking surgical relief is the direct cause of the complications. It is the general experience that complicated cases have usually had symptoms during a period sufficiently prolonged to have made a diagnosis possible before the development of serious lesions, and that an operation at that time would have been safer and cure more certain.

I would here refer to the clinical fact that a small number of patients who have had a cholecystostomy performed will have a colic or two following operation, and sometimes accompanied by transient jaundice. We have seen this most often during the first month or two after discharge from the hospital. In the large majority of instances the colics do not recur and the patient remains well. The temporary trouble is probably due to a crippled gall bladder becoming filled, and by reason of recent adhesions not emptying properly, so that based on a single spell of pain shortly after closure of the fistula a second operation may not be necessary unless there are other evidences of trouble.

The most common cause of future symptoms is incomplete removal of stones. In the original work of Tait, he advocated cholecystostomy and drainage based on the frequency of overlooking stones, as it enabled spontaneous discharge. In our early experience we had in one case 55 calculi work out of the fistula during the first two weeks. There is, however, little excuse for leaving stones in the gall bladder, as by using the finger as a guide it will be rare that even a small calculus will be overlooked.

Stones in the cystic duct frequently escape attention, and it was only after several such misfortunes that we began to exercise greater care in exploring this canal. The parts are deeply situated, and as these patients are often obese it was not easy to locate such a calculus previous to the development of the Robson technic. The sand bag under the back, with the high incision, usually enables us to dislocate the liver downward and outward, exposing both the cystic and common ducts. In most of these cases of stone impacted in the cystic duct cholecystectomy is indicated. The duct and cystic vessels are caught with curved forceps just beneath the impacted stone and tied. These structures are then cut across, and the gall bladder and duct with the stone removed from below upward, almost by traction alone, with an occasional division of some more firm adhesion to the liver. The gall-bladder notch in the liver should usually be drained down to the ligated duct to guard against leakage. Should there be difficulty in tying the vessels, the forceps may be left on and lightly surrounded with gauze. The forceps should be loosened in 36 hours, but not removed until 6 hours later. By this time the compressed tissues will have softened and allow easy withdrawal. Twice we have reoperated on cases in which the gall bladder had been removed distal to the stone, leaving it in the duct to cause future trouble. This is more apt to be the case when the gall bladder is dissected out from above downward. The deep field

* Read before the Mississippi Valley Medical Association, Memphis, Tenn., 1903.

is obscured by the blood and the same vessels are cut over and over again.

One source of failure of cholecystostomy to cure is from secondary obstruction of the cystic duct, preventing free drainage of the gall bladder down through the passages. This may eventuate in a mucous fistula or repeated attacks of colics as the gall-bladder secretions are periodically forced through the strictured canal. In some cases the gall bladder will distend and finally rupture through the scar, discharging bile and mucus. In practically all of these cases the cystic duct has been obstructed by stone, causing ulceration, the healing of which induces a stricture, or kinking of the channel may occur. Other things being equal, it is better to excise the gall bladder in all cases in which the cystic duct is involved. In this way we have of late eliminated this, the most common cause of secondary trouble.

In septic cases, drainage is necessary for a long period of time, and if the fistula be allowed to close too quickly, severe symptoms may ensue. We have twice had to reopen and re-establish drainage in septic cholecystitis; both cases were colon infections. This is less liable to happen in ordinary empyema of the gall bladder in which a fistula will usually remain until sterilization has been accomplished by natural processes. In colon infections tubage should be continued until the bile becomes sterile.

Stones are often overlooked in the common duct, as they may lie quiescent for years. The jaundice may be very slight and in some cases not noticeable. The gall bladder in the meantime may become obstructed at the cystic duct, so that this organ may be enlarged and cystic, with calculus at the neck and nothing to call attention to the common duct stone. This is so contrary to the usual condition of contracted gall bladder and open cystic duct in common duct stone as to lead to error. The ducts should be explored with the fingers before opening the gall bladder in every case. After opening the gall bladder the relief of tension prevents moving the stone in the dilated duct, and escape of the cystic contents is apt to soil the field. It is well to explore a second time after tapping, especially if the gall bladder is distended, but before opening the gall bladder with the attendant possibility of infecting the deep parts. If stones are found in the common duct it will usually be sufficiently dilated to introduce the finger into the duct for exploration. In many cases in no other way can we be sure the common and hepatic ducts are clear. If only one stone be present there will probably be jaundice as the duct may contract about it, while if the duct contain several stones the bile may pass by unless there be a large or obstructing stone at the duodenal end. In all of the cases of liver duct stones we have encountered there has been a large stone at the duodenal end of the common duct and stones of the same character in the gall bladder as in the hepatic duct. In one such case we removed 120 stones from the common and hepatic ducts with recovery of the patient.

Chronic pancreatitis may exist at the time of operation, and to obtain a good result drainage must be long continued. We have twice in such cases allowed the fistula after cholecystostomy to heal too quickly. The secondary symptoms were marked by attacks of slight jaundice and occasionally fever and chills, and rather persistent stomach trouble. At the second operation the only cause for the condition found lay in a chronic pancreatitis, and both cases were cured by cholecystenterostomy. We must in every case examine as to the condition of the pancreas at the same time we explore the ducts, and if this disease is present, either drain the gall bladder for a long time or do a cholecystenterostomy with the Murphy button, in addition to removing the stones. Stones still present, or recently so, in the common duct are the most common cause of chronic pancreatitis, and in two cases we were unable to feel a small stone in the common duct on account of the great size of the head of the pancreas. Prolonged drainage in one case failed to cure the patient, and secondary operation showed a stone in the common duct, but the pancreas had in the meantime greatly reduced in size.

In the second case, cholecystenterostomy was done with perfect relief for a year; return of pain and jaundice rendered a secondary operation necessary. The pancreas was found much smaller. The fistula between the gall bladder and duodenum had completely closed and a stone was found in the common duct. If the obstruction had remained I do not think contraction would have taken place. The drainage was followed by subsidence of the pancreatitis and reopening of the lumen of the duct, rendering the fistula unnecessary, and obliteration of the anastomosis ensued. Had it not been for the stone, cure would have resulted. Before deciding that chronic pancreatitis alone is responsible for the jaundice and symptoms, the common duct should be opened and explored with the finger.

Cancer can also be said to be secondary to stone formation, and may take place after cholecystostomy or, being present, may be mistaken for inflammatory disease. All thick-walled gall bladder should be looked on as suspicious, and as they are functionally useless, cholecystectomy should be done rather than cholecystostomy, and in this way many early cancers will be found and cured.

Early in this paper I spoke of having seen only one uncomplicated case which required a secondary operation. This was a cholecystostomy with a very large gall bladder, the stones were easily removed, and the ducts were free. For weeks after operation there was occasional escape of bile from the fistula, not much but troublesome. On dissecting out the gall bladder it was found that by a low attachment to the abdominal incision this viscus had formed a channel along which, in certain positions of the body, bile would gravitate outward. After cholecystostomy, the gall bladder should be attached as high up in the incision as is convenient.

Persistent biliary fistula usually means obstruction of the common duct. I take it that every one understands the importance of not attaching the gall bladder to the skin. In the early days persistent bile fistula was usually due to a mucocutaneous suture, the evils of which obsolete practice I do not need to point out.

The turning in of the margins of the incision in the gall bladder and drawing a purse-string suture closely about the drainage tube in a similar manner to a Stamm-Kader gastrostomy enables healing of the fistula to take place most promptly after removing the drain.

There are two rather common causes of failure to effect a perfect cure that may not always be avoided. Post-operative adhesions are liable to cripple the movements of the viscera in this neighborhood. Adhesions to the stomach and duodenum are the most annoying. Secondary separation may be necessary with the use of Cargile's membrane. As a rule, like the pain of old pleuritic adhesions, in time relief comes as bands stretch out. We make a rule not to allow gauze drains

to come in contact with the stomach and duodenum on account of the development of adhesions. We always interpose a piece of rubber tissue and leave it from 6 to 8 days, until the adhesive film surrounding the drains becomes organized. Hernia following operation for gallstone disease is not usually troublesome, but long incisions in obese people may give rise to serious hernial protrusion, requiring secondary operation. We now, if practicable, in such cases make a second opening outside the working incision, close to the ribs. Through this the drainage material may be brought out and enable us to carefully close the full length of the original incision. The necessity for this is increased if the opening has been extended downward for the purpose of removing the appendix.

Secondary operations have been comparatively safe in our experience. The patient has become accustomed to the condition and the adhesions form a protective barrier. Separation of the adhesions, particularly about the liver, results in considerable hemorrhage. Rather prolonged gauze pressure usually checks the oozing as the blood pressure in the liver is very low, and enables completion of the operation. Most of these cases require a light gauze drain protected by gutta-percha tissue at points of contact with the stomach or intestine to prevent troublesome adhesion to the gauze. Deep drains should be anchored with catgut to prevent displacement by movements of the liver as affected by the diaphragm. The catgut becomes absorbed before the time for withdrawal. The drains should not be removed too early, 6 to 12 days being the usual limits as to the time of withdrawal.

INTESTINAL ANTISEPTICS; THEIR USES AND LIMITATIONS.*

J. A. STORCK, M.D., Ph.M.

Professor of Diseases of the Digestive Apparatus, New Orleans Polyclinic; Professor of Physiology and Materia Medica, New Orleans College of Pharmacy; Visiting Physician to Charity Hospital and Turo Infirmary.

NEW ORLEANS.

The multiplicity of drugs used as intestinal antiseptics make it a difficult task to classify them under appropriate headings. Though of necessity in an imperfect manner, I have nevertheless made an attempt to group them, mainly as a matter of convenience in facilitating the presentation of this vast subject. Wherever I think proper, I shall eliminate, or make scant mention of, such agents as experience or reason has shown to be ill-fitted for the purpose under discussion. I shall give more time to such drugs only as have proved to be of decided value; while, in some instances, only a type drug of the group will be taken up, in order to abbreviate matters.

The excuse which I urge for mentioning this large number of well-known drugs is that I thought this an opportune time for establishing their proper place in therapeutics, and for reaching an understanding on what are, and what are not, intestinal antiseptics.

It is well that we now glance for a few minutes at some facts of history which directly and indirectly are associated with the subject under consideration.

It is to Leuwenhoeck, Miquel, Gautier, Selmi, Tanret, Brieger, Kühne and others that we owe much of our knowledge concerning intestinal bacteria, with their powers of producing fermentative and putrefactive changes of the food, and consequent alterations of the intestinal mucosa. The work of these men culminated in the theory of auto-intoxication, as first advanced by Humbert and greatly elaborated by Bouchard, to the latter of whom is due the credit of first bringing prominently to the attention of the profession the use of intestinal antiseptics.

It is well to clearly define the term antiseptic as I intend to employ it. According to the Century Dictionary, I shall use it as implying "anything which destroys the micro-organisms of disease, putrefaction or fermentation, or which restricts their growth and multiplication."

The first antiseptics which I will consider are those of the aromatic series. In using a quick poison like carbolic acid, great care must be exercised, as doses so small as seven minims have given rise to dangerous symptoms. For my own part, I have eliminated this agent from among those which I use as intestinal antiseptics. In small doses it is not effective, while in large doses it irritates the mouth, esophagus and stomach, causes gastritis and inhibits the activity of the ptyalin and pepsin. In order that a carbolic acid solution be effective in the intestine, it must remain therein for some minutes, and experience has proved that, when this takes place, toxic symptoms are liable to supervene. I have seen such symptoms produced after using a 1:300 solution for colon irrigation in the treatment of tuberculous ulcer of the large intestine, the solution being allowed to remain in the intestine only a few minutes. In one case I used a weak solution of sodium bicarbonate after the carbolic solution, yet toxic symptoms also developed.

Creosote (beechwood) given in doses of ten to fifteen minims in capsules or emulsions, or creosote carbonate in twenty minim doses gradually increased to ninety minims, is safer than carbolic acid; but, in large doses, the symptoms of poisoning by these drugs are somewhat similar to carbolic acid. In patients who show a tolerance to it, and in whom no gastritis or toxic symptoms accompanies its use, beechwood creosote proves a valuable aid in the treatment of tubercular ulceration. A pill containing creosote and coated with keratin has answered well in some cases; whereas, again, the pill passed out with the stools unaltered.

In order to secure the best action from creosote, whether given in pill, capsule, emulsion or whiskey, I find it most satisfactory to administer it about one to one hour and a half after food, as it then finds its way into the intestine sooner than otherwise.

This mode of administration holds good also of all the creosote derivatives. When tolerated in large doses, I find creosote more valuable than its derivatives, guaiacol, guaiacol carbonate, etc.

Kuprianow[1] reports the restraining effect of guaiacol to be 1 to 500 on the cholera spirillum, and suggests its use in the treatment of cholera. When used alone in the treatment of the diarrhea of typhoid fever, I failed to get any good results, and in several cases of that disease I found that it depressed the patients very much, even in doses so small as three minims.

With guaiacol carbonate I have had an extensive experience in both hospital and private practice, using it, in tubercular enteritis, by the mouth in five to ten grain doses, at the same time using tannic acid by colon

1. Sternberg: Text-Book of Bacteriology.

irrigation. Employed in this way, I have seen good results follow. My experience with this drug, when used alone, in the treatment of the diarrhea of typhoid fever has not been very encouraging. In my own cases, only once have I seen any evidence of toxicity (smoky urine, etc.). This was in a case where I used ten grains four times daily; but I have had patients complain of slight heaviness (indigestion) in the stomach even after five-grain doses, particularly if the drug had been long continued.

As for benzosol, my limited experience with it has not proved that it possesses any superiority over guaiacol carbonate. True, I never noticed any digestive disturbances or toxic symptoms, but then I never exceeded six grains to the dose.

For a long time resorcin held high place as an intestinal antiseptic, especially in the treatment of fermentative conditions in the intestines during infancy and childhood. However, owing to its deleterious action on the kidneys, I have come to use it seldom, and then with caution.

When using salol, the fact should not be lost sight of that it contains 36 per cent. of phenol, and that its use, especially in large doses, has caused, and is liable to cause, symptoms of carbolic acid poisoning. I have seen marked symptoms of carbolic acid poisoning after the administration of two 20-grain doses ten hours apart; and also in two other cases, where the dose given was 10 grains three times daily. In one case the toxic symptoms manifested themselves after nine doses, and in the other case after fifteen doses had been taken. When used alone for the diarrhea of typhoid fever and in dysentery, it has not yielded good results; but improvement has followed its use in simple diarrhea and in the summer diarrhea of children. It is recommended in Asiatic cholera, a condition with which I have not had any experience.

Though an efficient antiseptic, salicylic acid has its limitations. Its pronounced effect on ptyalin and pepsin should be borne in mind as influencing its mode of administration; and, where possible, its sodium salt, which is not so irritating to the kidneys nor so destructive to the digestive ferments, should be substituted. I use salicylic acid in the strength of 3:100 by colon irrigation. A small quantity of sodium borate increases its solubility. In the treatment of diseased conditions of the lower bowel where antiseptic medication is indicated, it has given good results in my hands. In amebic dysentery, where quinin is objectionable for any cause, salicylic acid has often proved efficient.

All the indications are that benzoic acid possesses the same qualities as salicylic acid, and, being less irritating, it should be used more generally than it is at present.

While creolin possesses decided germicidal properties, the fact that toxic symptoms have developed after its use by colon irrigation and vaginal douches, should put us on our guard. The results obtained with creolin are about the same as with carbolic acid, but Behring has shown that, in albuminous liquids, creolin is less effective than carbolic acid

Naphthalin and naphthol are useful agents in treating intestinal conditions where the contents of the bowel are in a state of putrefaction. They are of little, if any, value in diseases of the intestines where the walls of the intestines are the primary seat of the intestinal trouble, i. e., in typhoid fever.

Benzonaphthol is inferior to naphthalin and naphthol. As for hydronaphthol, I find no difference in its action from that of the two drugs last mentioned.

Naphthalin and its derivatives should not be used in any case where the kidney, bladder or urethra are diseased. Purdy has seen a 5-grain dose produce severe burning along the whole urinary tract.

Thymol is more destructive to putrefactive organisms than carbolic acid. It has been used with some success in the treatment of tuberculous ulcer of the intestine and in chronic infectious enteritis, and is also used for the same conditions as is naphthalin, but, like naphthalin, it is very liable to produce renal irritation.

Ichthyol has a champion in Hemmeter,[2] who claims excellent results by colon irrigation in colitis; also in enteritis with the emission of offensive flatus and meteorism. He further recommends it in conjunction with bismuth subnitrate and subgallate, by colon irrigation in chronic dysentery. He uses mixtures containing from one to four grams to the liter of water.

Eucalyptol seems to be devoid of any good as an intestinal antiseptic.

Owing to the property that tannic acid possesses of causing indigestion when used in large enough doses to be of value, I have entirely discarded its use by the mouth, and now confine myself to the use of it by colon irrigation. It has proved of value in acute and chronic infectious enteritis; and in tubucular ulcer of the lower bowel it is one of the most valuable agents which we possess. Before using the colon irrigation, the bowel should be well cleansed with plain sterilized warm water, or a warm normal saline solution. One liter of warm tannic acid solution 1:500 or 2:500, should be introduced into the lower bowel and allowed to remain for 10 or 15 minutes.

When used by the mouth, tanniform is of considerable value in the treatment of tuberculous ulcer above the ileocecal valve, especially if combined with tannigen, tannalbin or other drugs of this class.

We will next consider the peroxid series. Hydrogen peroxid is indicated in any condition of the lower bowel where pus is in evidence. Another body analogous to hydrogen peroxid, and which gives much promise of efficiency, is benzoyl-acetyl-peroxid (acetozone). Drs. Freer and Novy[3] have made extensive researches into its germicidal action, and have reached results which prove it a superior germicidal agent. It has been used by Dr. Wasdin[4] and others in the diarrhea of typhoid fever; and Drs. Freer and Marshall[5] report good results in cholera and dysentery.

Dr. R. T. Strong of the Biologic Laboratory, Manila, says: "Quinin in enemata has usually given the best results in the treatment of amebic dysentery. The advantages of acetozone over quinin are quite apparent. It is capable of killing amebæ even in dilute solutions, and attacks the bacteria which are present in the intestines, greatly reducing the number of micro-organisms in the stools." My own experience is confined to the use of acetozone in six cases. In two cases of intestinal tuberculosis, the bowel condition grew better after the third day, and the patient gained in strength and weight. In one case of advanced pulmonary tuberculosis accompanied with intestinal lesions, no improvement

5. Drs. Freer and Marshall: U. S. Government Laboratories Manila.

was noticed. In three cases of typhoid fever with diarrhea, the improvement of the bowel conditions was everything that could be desired, and the patients made excellent recoveries. The stools were almost completely deodorized after 48 hours.

The group next in order is the sodium series. When I wish to give preparations of salicylic, benzoic or carbolic acid by the mouth for any condition in the duodenum, or high up in the small intestine, I prefer the sodium salts of the above mentioned acids as antiseptic agents, my preference being sodium salicylate. Holt[6] thinks well of this salt in the summer diarrhea of children.

Now we come to the bismuth, magnesium, calcium and aluminum series. Owing to the feeble antiseptic action of the salts of the last three drugs, they have not met with much favor as intestinal antiseptics.

The salicylate and subgallate of bismuth are agents of some value. When an insoluble preparation is indicated, as in the treatment of tuberculous ulcer in the lower part of the ileum and of the cecum, bismuth betanaphthol answers a good purpose.

Among the miscellaneous series, I will first consider carbon disulphid. Dujardin Beaumetz says of this agent: "I have obtained most satisfactory results from the point of view of intestinal antiseptics." He further claims it to be superior to all other medicaments in favorably modifying putrescent intestinal processes in typhoid fever. Beaumetz[7] cites M. Ckiandi-Bey and Sapelier concerning the non-toxicity of carbon disulphid.

Oil of turpentine has given marked results in the treatment of some cases of tuberculous ulcer, especially in cases with pronounced flatulence, improvement in the condition of the stools and in the general condition of the patient took place rapidly.

As for boracic acid, it has not yielded any results in my hands.

Where fermentative conditions, marked by meteorism and tympanites, are very active in the bowel, sulphurous acid is, for the most part, safe and fairly sure.

While reliable as an antiseptic, formicaldehyd causes much burning, even when used in weak solutions.

Where the seat of the disease is in sight and may be easily reached by applications, nitrate of silver proves a valuable antiseptic as well as astringent. Otherwise, owing to its rapid change, it is of doubtful antiseptic worth.

Up to this time, in the treatment of amebic dysentery, no other agent has given me as good results as quinin. I have used both the sulphate and hydrobromate, and give preference to the latter.

Owing to its easy and rapid decomposition, nothing much could be expected of such a chemical as potassium permanganate as an intestinal antiseptic.

In doses large enough to be of benefit as an antiseptic, iodoform irritates the stomach.

Lactic acid, which for a long time enjoyed a reputation in the treatment of the summer diarrhea of children, has been largely replaced by hydrochloric acid. Vaughan[8] says, in speaking of the summer diarrhea of infancy: "The only digestive secretion which is known to have any germicidal effect is the gastric juice (hydrochloric acid); therefore, if this secretion be impaired, there is at least the possibility that the living germ will pass on to the intestine, will there multiply and will, if it be capable of so doing, elaborate a chemical poison which may be absorbed." In conditions of the stomach where there is a deficiency of hydrochloric acid in the gastric juice, and where, in consequence, putrefactive changes in the intestine take place, hydrochloric acid is indicated; for, as the experiments of Hammarsten[9] show, "putrefaction does not occur in the small intestine as long as the contents are strongly acid."

Whenever an eliminant and antiseptic is required at the same time, calomel is the agent to be employed. It is one of the safest and surest agents in fermentative and putrefactive conditions existing in the small intestine. Ox gall, especially when combined with calomel, is of value in fermentative conditions due to deficient flow of bile.

While we believe that too much importance has been attached to the significance of the presence of etherial sulphate in the urine as an index to the amount of proteid decomposition going on, yet we can not agree with Boas[10] when he says that "the determination of etherial sulphates in the urine is of no value." If that be true, then the experiments of Nencke, Kühne, Jaffé, Baumann, Brieger, Hoppe-Seyler, Hirschler, T. R. Müller, Helden, Wesener, Winternitz, Carl Schmitt and others are of no value. For, if their conclusions prove anything, it is that when proteid decomposition in the intestine is active from any cause, etherial sulphates are increased in the urine.

I may state in conclusion:

1. Never lose sight of the patient.

2. Holt says that no matter how much we believe in drugs, if they continue to disturb the stomach they are worse than useless.

3. Care should be exercised in the selection of a proper antiseptic; it should be non-toxic and non-irritating.

4. Care should be exercised in the selection of the diet, that it be of such a character as not to favor bacterial growth.

DISCUSSION.

Dr. O. T. Osborne, New Haven, Conn.—Emphasis should be placed on the fact that carbolic poisoning can occur from sources easily overlooked. I am a great user of salol, but when I administer it for more than a day or two at a time, and in all typhoid cases, I have the urine constantly watched, and if I find a trace of albumin the salol is stopped. There is probably no better antiseptic for the alimentary canal unless it be calomel. The treatment of typhoid with a drop of carbolic acid with the idea that this will have an effect on the intestines, I think is almost mythical. If ulceration is going on in the intestines they should be kept as clean as possible, and the diet should be such as will leave the least possible refuse. In children with diarrhea we should stop all carbohydrates and by intestinal cleanliness and judicious purgatives render the canal as antiseptic as possible.

Dr. George F. Butler, Alma, Mich.—In every instance in which I have treated cases with acetozone the patients did better than with anything else, though in several instances I had to discontinue it temporarily on account of the accumulation of gas in the stomach, but it could be renewed later. I have noticed few untoward results. In three cases there was excessive nose bleed and it occurred to me that the acetozone might have exercised some influence in producing this. In my country I have never had occasion to use quinin as an intestinal antiseptic, but in the south where there is some malaria we must take that into consideration and might have to use quinin Irritation to the mucous membrane is a possible difficulty with the use of this drug. I prefer the benzoate of guiacol to salol, as the former breaks up into benzoic acid and guiacol, both of

10. Boas: Diseases of the Intestines, 1901.

which are good antiseptics, and with it we get fairly good results without gastric disturbance. I am still inclined to think that sterilized water and the washing out of the bowel is as good as anything. The internal administration of antiseptics has not proved of special value in my hands. Taken altogether I am inclined to think that acetozone is the best of the intestinal antiseptics.

DR. W. J. ROBINSON, New York—Most physicians think that creosote and carbolic acid act nearly alike except that creosote is somewhat milder. This is due to the fact that there is a coal tar creosote which is sometimes ignorantly or maliciously substituted, and which is for all practical purposes carbolic acid. The beechwood creosote is entirely different, and contains 75 per cent. of guaiacol and can be given in large doses, gradually increasing it up to 60 minims several times a day without any bad symptoms, while carbolic acid can not be so administered. I think this point should be emphasized; the text-books do not make this distinction sufficiently marked. I think resorcin should be entirely eliminated from our pediatric therapeutics, because in young children it produces very dangerous effects, even in small doses; it ought to be and can be replaced by safer drugs, especially in pediatrics.

DR. SOLOMON SOLIS-COHEN, Philadelphia—Ichthalbin has not been mentioned. This seems at times to be well borne by the stomach when ichthyol disturbs, and in my experience it has been efficient in certain cases. In intestinal sepsis we do not know just what drugs are indicated because we do not as yet know precisely what organisms are at work, what chemical changes are going on, and how best to neutralize them. We can, therefore, with propriety combine a number of drugs, none in sufficiently large dosage to do harm, but each, perhaps, if not sufficient to kill certain microbes or groups of microbes, sufficient at least to limit their activity; all combined thus limiting the septic action of many groups. An illustrative combination for such purpose is guaiacol carbonate, benzonaphthol, and bismuth salicylate. At times we may produce an effect indirectly. Thus castor oil and saline irrigations exert antiseptic influence by cleansing the bowel. I am perfectly satisfied that the endeavor to restrict fermentative, putrefactive and other toxicogenic processes in the intestinal canal in typhoid fever, otherwise than by the external use of cold water, is good treatment.

DR. B. C. KEISTER, Roanoke, Va.—A constant standby with me for some time has been sulphocarbolate of zinc combined with elixir lactopeptone or pepsin cordial. In treating intestinal indigestion, dysentery and typhoid, good results may be expected from a fair trial of this old friend.

DR. J. A. STORCK—I have not noticed hemophilia occurring after the use of acetozone in any of my patients. I have found the hydrobromate of quinin less irritating than the sulphate. In the case of poisoning following creosote I had used Morrison's beechwood creosote, and I had every guarantee of its genuineness. I have entirely discarded the use of mercuric bichlorid and copper arsenate. I do not believe drugs of that kind ought to be used.

NOTES ON PULP TECHNIC.*

MARTHA ANDERSON, M.D.
MOLINE, ILL.

The comparative value of methods and stains used for nerve tissues in other parts of the body has never to my knowledge, been demonstrated on the pulps of teeth. Our studies for the past four years have been along this line. While this work has not been complete, yet we are able to show some results. A complete summary of this work however, remains for the future. This line of research is to be continued. I herewith submit the results of my investigations for the past year.

In the work of preparing pulps for the demonstration of nerve tissue the following methods of procedure have been carried out:

Fresh pulps have been hardened in a weak solution of formalin, in Müller's fluid, Ehrlich's fluid and in Weigert's chrome alum solution. The formula of the latter is as follows:

Chrome alum	2½ per cent.
Copper acetate (neutral)	5 " "
Acetic acid	5 " "
Formalin	2 to 4 " "

Dissolve the alum in the necessary water, add acetic acid, then copper acetate. Filter, and when cold add formalin.

Sections were cut by the freezing method, then stained by one of the following methods:

(A) WEIGERT'S METHOD FOR MEDULLATED NERVES.
Copper acetate neutral sat. Aq. sol. + aq. dist., āā (warm), 24 hours.
Wash.
Weigert's hematoxylin, 24 to 48 hours.
Weigert's differentiating sol., few minutes.
Wash.
Dehydrate, clear and mount in balsam.

(B) OSMIC ACID AND HEMATOXYLIN.
OsO_4, 1 per cent., ½ to 1 hour (dark).
Wash.
Pyrogallic acid, 5 per cent., 2 to 4 minutes.
Wash.
K permanganate, ¼ per cent., 3 to 4 minutes.
Wash.
Oxalic acid, 1 per cent., ½ minute.
Wash.
Counterstain in hematoxylin.
Wash, dehydrate, clear and mount.

(C) MUMMERY'S IRON AND TANNIN.
Wash sections in distilled water.
Liquor ferri perchlor., B. P., 24 hours.
Wash quickly in distilled water.
Tannic acid, gr. ii in 3iss aq., 5 to 10 minutes.
Wash, dehydrate, clear and mount.

(D) IRON AND HEMATOXYLIN.
Zenker's fluid.
Wash.
Mordant—liquor ferri chlor., 24 hours.
Wash thoroughly.
Hematoxylin, ½ to 1 per cent. aq.
Wash well.
Decolorize weak mordant till pale straw.
Wash thoroughly (or will fade).
Dehydrate, clear and mount.

(E) FREUND'S GOLD.
Wash water.
$AuCl_3$, 1 per cent., 3 to 5 hours (dark).
Wash.
Caustic soda, 1 to 5 or 6 water, 3 minutes.
Drain.
KI, 10 to 12 per cent., 5 to 15 minutes.
Wash, dehydrate, clear and mount.

(F) UNDERWOOD'S GOLD.
Wash in Na bicarb. sol. gr. v in ʒi aq.
$AuCl_3$, neutralized by Na bicarb. sol. gtt. by gtt., ½ hour (dark).
Wash dist. water.
Formic acid, 1 per cent., warm and keep rather hot till crimson, ½ to 1 hour (dark).
Dist. water, cold, ½ hour.
Dry.
Mount in glycerin jelly.
Avoid Canada balsam.

(G) LEMON JUICE AND GOLD.
Lemon juice strained several times through flannel 10 to 15 minutes.
$AuCl_3$, 1 per cent. (dark), 1 hour.
Wash rapidly.
Formic acid 25 per cent. (dark), 24 hours.
Transfer to glycerin and mount in glycerin.

Weigert's stain for medullated nerves was used on tissues hardened in Müller's fluid, formalin and Weig-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. M. L. Rhein, M. H. Fletcher and Wm. E. Walker.

ert's chrome alum, and good results were obtained with both Müller's and formalin hardened tissues, the medullated sheaths of the nerves taking the stain.

The osmic acid method was used similarly to the above, and gave good results following Weigert's chrome alum solution.

Mummery's iron and tannin used after Müller's fluid stained the nerve fibers, but the results were not so good as with the two previous stains. Mr. Howard Mummery, however, has been able by this stain to trace fine nerve fibers from the nerve bundles.

Iron and hematoxylin gave good results, the fibers in some places being traced to the apex of the pulp.

Of the different gold methods, Freund's has given me the best results, although some of the results of staining tissues hardened by all the methods have been good. Gold staining, on the whole, has been unsatisfactory. The staining has been unreliable. In carrying a number of sections through together by the same process some will be acted on, the stain showing a good result; others will be unaffected. The tissues that turned out well yesterday will be a failure to-day and from no apparent reason.

With certain of the nerve stains the pulp stones have taken the same stain as the nerve tissues. The osmic acid method is an exception, the stain reacting differently on the stones.

A SIMPLE METHOD OF TREATMENT OF HEMANGIOMA.

CARL BECK, M.D.
Professor of Surgery and Surgical Pathology, Post-Graduate Medical School and Medical School of the University of Illinois.
CHICAGO.

During the last few years the treatment of hemangioma (nevus) has received considerable attention. The excision of the tumor as a whole, which has been practiced universally, has not proved a very satisfactory procedure. It is only of use when the angioma is small, so that primary union of the wound is possible. Whenever the tumor is large in area or very deep it is of very little value. Especially the treatment of angioma of the face is a difficult task, as it seldom appears as a tumor which could be removed *in toto*. Injections of hot water, lately recommended by Wyeth, if done properly and carefully, are satisfactory, and are a valuable addition to the therapy, but we have no means to limit the fluid in its action, and when once injected it will flow in the direction of the least resistance and is beyond our control. The introduction of magnesium nails (Payr) is another new and highly recommended method, but its use will be limited to small tumors.

It seems to me, therefore, advisable to publish a method which I have used a number of times, and of which I exhibited a very successful case at the November meeting of the Chicago Medical Society. The case is remarkable in many respects, but instead of describing it in detail, I shall give only a few brief notes, and from the two pictures added it can be seen how far the angioma extended and what the result of the treatment is. When three months old (Fig. 1) this child was brought to me with a very extensive hemangioma of the face (variety, hemangioma arterio-venosum). It was composed of several different growths, with small islands of normal epidermis between them, and its extent was such that some surgeons declared it inoperable. This it was certainly for the ordinary method of excision, but with the method which I describe below, it proved curable, and even the cosmetic result is good, as Figure 2 shows.

The method consists in the general principle of transforming the masses of vessels gradually into connective tissue. Gradually means in several sittings. This is done by a subcutaneous suture. A thread of catgut is passed in a zigzag manner, first below the skin, then underneath the base of the tumor; then, again, underneath the skin, underneath the tumor, etc., until the tumor mass is included in this continuous suture. This suture is drawn tight and closed at the point of the entrance of the needle. In this manner the circulation is shut off within the tumor, but no gangrene follows, inasmuch as some blood can yet reach the parts not included in the suture. After about a week the mass of the tumor seems much smaller. The normal epidermis, however, outside of it, which had been stretched, sometimes to considerable tension, becomes soft and elastic again and grows. This procedure is repeated until the tumor has been diminished to the smallest possible nodule of

Fig. 1.—After a few sittings, showing small islands of normal skin between angiomatous growth.

Fig. 2.—Photograph, four years after operation, no trace of angioma, a small nodule of connective tissue in the left nasolabial fold.

connective tissue, and the healthy skin enlarged to the utmost. Then the hard connective masses are excised and the borders united in fine linear union. If the tumor is growing in patches, as often happens, one will see the islands of normal skin enlarge within a few weeks to twice and three times their size.

This treatment applies to all varieties of hemangioma, but in the arterial and mixed varieties it is necessary to ligate the largest afferent vessels. Only in this way is one able to check the often rapid growth of these tumors.

In this way we had to proceed in the case published herein, and had to excise a portion of the common carotid artery, otherwise we should never have checked the growth of the tumor.

New Appliance.

A NEW TENT FOR THE TREATMENT OF TUBERCULOSIS.

IRVING FISHER.

Professor of Political Economy at Yale University, and Secretary of the New Haven County Anti-Tuberculosis Association.

NEW HAVEN, CONN.

VARIOUS DEVICES FOR OUTDOOR SLEEPING.

In the United States the vogue and the wonderful success of sleeping out of doors as a means of curing tuberculosis has led to a number of different devices, such as tents, sleeping balconies, etc. In Colorado and California, during the rainless months, sleeping on the ground is often practiced, in which case only a cowboy's tarpaulin, a sleeping bag or a camp mattress may be used. A more comfortable arrangement is a sleeping veranda built next to the house, so that the patient may easily step from his dressing room to his bed and back again. A simpler plan is to project the head of the bed out of the patient's bedroom window, protection from the weather being secured by canvas awnings and curtains. This method has been perfected by Dr. T. M. Bull of Naugatuck, Conn., although previously employed by Dunham.[1] It has the great advantage of being cheap and easily applied to tenement houses and flats where there is no room for any larger structure. A "shack" has been used by Dr. Millet in his sanatorium at East Bridgewater, Mass. This is a small wooden building open to the air on three sides and fitted with windows and curtains which may be closed in bad weather.

Finally, there are various types of tents. Beside the ordinary "A" tent or wall tent there are the up-draught tents of Sibley, Munson, Holmes and Gardiner. The last named is modeled after the Indian tepee, the air entering through a slit around the circular floor and being vented through a hole in the top. Of these various devices, the sleeping balcony, the Millet shack and the Gardiner tent seem to me the best.

THE PRINCIPLE OF VENTILATION.

The tent described below is an attempt to combine the advantages of these. The object is to provide pure air to the occupant under all conditions of weather, without sensible draught. The essential idea is to force a gentle current of air vertically upward through the tent. The breath of the occupant naturally rises, and is then caught in this upward draught and carried out, so that there can be no possibility of its being rebreathed.

The rapidity of change of air to effect this result need not be great. Ventilating engineers usually make a fundamental mistake in treating the problem of ventilation as though it were to add pure air to a room, whereas the principal problem is to remove the impure air. Ordinary ventilation simply dilutes this impure air instead of removing it systematically as fast as formed and preventing its return to the nose. The quantity of air passing through this tent is considerably less than what passes through an ordinary tent with horizontal air currents; but the air breathed by the occupant is absolutely pure, instead of slightly contaminated, as it is in the ordinary tent.

DESCRIPTION OF THE AUTHOR'S TENT.

The tent floor is 10x14 feet, the walls of the tent are 8 feet high under the eaves, from which rises a pitched roof to a central cupola, which is 4x5½ feet in horizontal dimensions and three feet in height. A smaller size, capable of holding one bed only, is 9x9 feet; height, 7 feet; cupola, 3x3x2½ feet.

The tent is raised a yard above the ground. The air enters the space beneath the floor through louvre-boards or "luffer-boards" or "flaps" of cloth, which are simply like clapboards hinged at the upper edges and hanging one over the other. These flaps are hung at their upper edges by cords on the inside of a wire netting surrounding the base of the tent. Thus they open inward at the slightest wind pressure, allowing every breeze to enter the space beneath the floor, but not allowing it to escape, since the pressure from the inside against the flaps closes them. The air is thus forced up through the tent. Similarly, the sides of the cupola are provided with flaps of the opposite kind; that is, they are hung on the outside of a wire netting and yield to any effort of the air to escape from the tent, but close against any wind from the outside. The effect, therefore, is to produce "wind pump ventilation," and to transform the slightest breeze into an upward current.

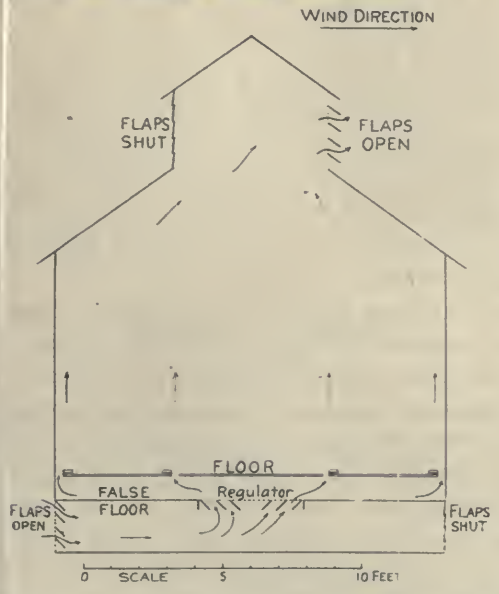
Free passage of air through the floor is provided by a space three inches wide between the tent floor and the walls of the tent and also by two slits two inches wide in the floor, four feet from each end. These slits, as well as the openings on the four sides, may be closed by trap doors so that the tent may be temporarily heated in the morning when the patient wishes to dress.

The length of the tent runs in an east and west direction. The entire south wall consists of curtains which roll from the bottom on Hartshorn rollers and may be put down in the day time to sun out the tent, or on hot, close summer nights when the air is absolutely still. In cold weather, even when the air is still, the curtains need not be lowered, as the difference in temperature between the breath exhaled and the surrounding atmosphere is enough to cause the exhalations to rise and pass out of the cupola openings. To provide for this there is a small space above the flaps in the cupola always open, and also above the flaps around the base of the tent.

One other device needs to be explained. This is a "regulator" under the floor of the tent and in the center. It performs two functions: the first and most important is to distribute the air evenly to all four sides of the tent; the second is to check the motion of the air when it is excessive, as in a gale. A false floor of canvas is constructed a foot below the real floor, and in the center of this false floor is an opening 5x7 feet, covered with wire netting and provided with flaps like those already referred to but hanging down from the wire netting at an angle of less than 45 degrees. Half of them, namely, those toward the east, are hung at their east edges; the other half, namely, those toward the west, are hung at their west edges. The consequence of this arrangement is that the air, passing through these flaps, is distributed half toward the east and half toward the west, so that each end of the tent is supplied with its share of air, whatever the direction from which the wind is blowing. It is found that without this distributing apparatus the air is apt to come up on the side of the tent most remote from the direction of the wind, and even in some cases to produce a revolving motion of the air in the tent, causing a down current on the windward side. With the regulator, however, this never happens.

In case of a gale the flaps in the regulator, which usually hang open, are blown shut and keep out an excessive quantity of air. The flaps at the extreme east and west are lightest and close first. The weights of the remaining flaps are graduated, so as to close successively in proportion to the severity of the wind.

The wire netting to which these flaps are attached is surrounded by canvas screens projecting seven inches downward



1. Observations on Tuberculosis, Dr. Henry B. Dunham, American Medicine, Dec. 28, 1901.

from the false floor, so as to constitute a short shaft, as it were, thus compelling the air, before reaching the flaps, to already have a general upward direction.

The mechanism which has been described thus performs four functions:

1. The flaps surrounding the base of the tent act like in-draught fans.

2. Those in the cupola act like suction fans.

3. Those in the central opening in the false floor distribute the air evenly.

4. The latter also check excessive draughts.

The result is that the tent automatically provides pure air for its occupants, without draughts, and in all conditions of weather, with the single exception of weather which is both hot and still, in which case it becomes necessary to lower the curtains.

The tent has been put to several severe tests. In one of these tests a stove was placed in the center, with the stovepipe extending only a foot above the head. It was found that the smoke thus vented into the tent itself was all carried out through the cupola without even producing any odor perceptible to those in the tent.

COMPARISON WITH THE GARDINER TENT.

The tent is simply a combination of the main features of the Gardiner tent, devised by Dr. Charles F. Gardiner of Colorado Springs,[2] the Millet shack, employed by Dr. Charles S. Millet at his sanatorium at East Bridgewater, near Brockton, Mass., and the movable cloth flaps frequently employed by heating engineers in cold air boxes. The combination of these three devices avoids some of the objections which apply to the Gardiner or Millet structures. Those points in which it is thought to be superior to the Gardiner tent are:

1. One side can be made entirely open in still, hot weather or in the daytime for the purpose of sunning the tent. This is important in damp climates. The Gardiner tent has been chiefly used in Colorado where there is never need of opening it up to dry it out.

2. The very slightest breeze is caught by the flaps and forced through the tent.

3. The flaps prevent automatically any possible down-draught, which sometimes occurs with the Gardiner tent when overtopped by a building or tree to the windward.

4. The regulator prevents any possible draught across the floor.

COMPARISON WITH THE MILLET SHACK.

The points in which the tent aims also to overcome objections to the Millet shack are:

1. The patient is not subjected to strong or variable winds.

2. He is not forced to sleep with the glare of the sky in his eyes.

3. There is no need of any adjustment by the patient at night in case of a storm or a change in the direction of the wind, as the tent adjusts itself automatically.

As yet, only a few of these tents have been made. Those who have used them have been greatly benefited. Some are to be employed at the new sanatorium of the New Haven County Anti-Tuberculosis Association at Wallingford, Conn., and one will be exhibited at the meeting at Baltimore, in January, 1904, of the Tuberculosis Commission of Maryland.

SOME DETAILS.

There is a double roof to prevent leaking.

The flaps in the cupola must be waterproof.

All flaps have the corners cut off obliquely, as square corners will whip and make a troublesome noise.

The flaps are tied by cords running obliquely downward. The cords must be loose enough to provide for shrinkage in damp weather, and yet tight enough to prevent the flaps from fluttering in the wind.

The false floor is made in sections easily detached and cleaned.

The cupola and the window in the false floor are lined with mosquito netting.

The curtains run between guides constructed of soft rope, so as to act as noiseless cushions. Cords from the curtains pass over pulleys at the northeast or northwest corner of the tent and thence to cleats on the east or west wall, so that the patient may operate the curtains without leaving his bed.

The curtains must be so adjusted in length that when they are pulled entirely up the Hartshorn metal rollers have the slit downward; otherwise the rain will percolate inside the rollers and injure them.

There is always an open space of one inch above the flaps in the cupola.

There is no patent on the tent. Anyone is free to construct one on the basis of the foregoing description.

2. This tent is fully described by Dr. Gardiner in his pamphlet entitled "The Sanatory Tent and Its Use in the Treatment of Pulmonary Tuberculosis." (Reprinted from Transactions of the American Climatological Assn., London, 1902, John Bale, Sons & Danielson, Ltd.)

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

103 Dearborn Avenue . . . . Chicago, Ill.

Cable Address . . . "Medic, Chicago"

Subscription price . . . . . Five dollars per annum in advance

SATURDAY, DECEMBER 26, 1903.

The large amount of space occupied by the index in this issue compels us to omit several departments and to curtail others.

A WORD AS TO THE INDEX.

This issue completes Volume XLI of The Journal and contains the index. Since this index is peculiar to this journal, requires an immense amount of work and expense in its preparation and production, and is, we believe, of great value to those who desire a ready reference to medical literature, we again call special attention to it. We do so because we are afraid that few of our readers realize that this is anything more than "just an index"; consequently its value is limited.

The index is in two parts; the first running to page 1603. This is simply the ordinary index to the contents of The Journal itself, such as usually accompanies other journals, except that, we believe, ours is fuller and more complete. The second part of the index, commencing on page 1604, is that which is unique to our journal and to which we wish to call attention. As our readers know, we give each week the titles of original articles which appear in the leading medical journals of this and other countries. The index to the "Current Medical Literature" is an index to these articles. In other words, it is an index to the important literature of the world for the six months covered. To those who desire to look up any subject it is therefore invaluable.

The important articles are abstracted, but if these are not full enough, or if the article is not abstracted, the original article can nearly always be had by writing to the publisher, if in this country, or by referring to some of the leading libraries if it is a foreign journal.

A matter of minor importance to the possessor of a bound volume of The Journal but of great moment to him who has his journals loose, is the awkwardness and the annoyance of turning to the copy and to the page to find the titles. To do away with this, we issue, at the nominal price of fifty cents, a reprint of this index to which is added all the titles above referred to taken from The Journal week by week. Thus is provided in a compact and convenient form a reference to the literature contained in the leading medical journals of the world.

THE DETERMINATION OF SEX.

Many theories of the possible determination of sex in the lower animals have been broached in the last quarter of the century. At times it has seemed that influences could be brought to bear on the fertilized ovum that would artificially determine its sex, or at least so influence a number of ova that the majority of the offspring would be of one sex rather than the other. Prof. Thomas Hunt Morgan,[1] the director of the biologic department of Bryn Mawr College, and very well known for scientific work of a high order in embryology, and in the subject of regeneration, has made a review of all the recent investigations with regard to the determination of sex, and concludes that so far nothing definite has been discovered, and that very probably the sex of the embryo is in most cases determined in the ovum or during the process of fertilization, after which no subsequent influences can change this determination.

There have been apparently good reasons for thinking that in some cases sex might be determined after the fertilization of the ovum. Statistics of population seem to show that after long and severe wars in which many men are killed and the male part of a country's population is greatly decreased, there is for several years a preponderating birth of male children until the normal proportion between the sexes is restored. This seems to have been noted after the Thirty Years War in Germany, after the Napoleonic wars in France, and even in more recent times, after the Siege of Paris. It was thought that the increase of male births supposed to be noticed after such times of calamity, was due to the fact that the female population suffered hardships and that such a condition of hardship had a biologic effect in the production of males rather than of females. This theory seemed to be borne out some twenty years ago by experiments on frogs. The feeding of tadpoles very abundantly was reported to lead to an over-production of females, while the starving of tadpoles led to the production of males. Unfortunately, subsequent observation showed that this investigation was incomplete. As a rule, in any brood of tadpoles a great majority of them will turn out to be of one sex or the other. There is not the equal division of sexes that might be expected. Accordingly, the supposed conditions of the experiment are quite different from what the original investigator considered them to be.

Cuenot, who has perhaps done the best original work on this subject of the possible determination of sex, says that "the classic examples of insects and frogs, in which it was supposed that external conditions acting on the later embryo determined the sex, have been shown to be capable of a different interpretation. It has especially been made clear that a meager or an abundant supply of food has no influence on the determination of the sex of the embryo." It is the egg, in his opinion, and not the spermatozoön that determines the sex of the individual. This is true beyond all doubt in many insects, in pigeons, and in certain of the lower animals. In some animals, as the rotifera and in the social hymenoptera, the

1. Popular Science Monthly, December.

spermatozoön appears, however, to have a determining influence.

As a general conclusion Professor Morgan considers that it may be a futile attempt to try to discover any one influence that has a deciding influence for all kinds of eggs. "Here, as elsewhere in organic nature, different stimuli may determine indifferent species which of the possibilities that exist shall become realized." In a word, instead of a simple, it is a very complex problem, and all our supposed knowledge on the subject fails to stand the rigid test of scientific examination by the trained, modern biologists, whose wider knowledge of the lower animals has enabled them to recognize sources of error in previously suggested solutions of this attractive but inscrutable mystery.

Medical News.

CONNECTICUT.

November Infectious Diseases.—During November one case of smallpox was reported; 643 cases of measles, with 2 deaths; 132 cases of scarlet fever, with one death; 182 cases of diphtheria, with 4 deaths; 86 cases of whooping cough, with one death; 79 cases of typhoid fever, with one death, and 29 cases of consumption, with 20 deaths.

National Guard Changes Suggested.—At an informal meeting of the surgeons of the Connecticut National Guard, New Haven, December 9, it was decided to recommend to the military authorities that a medical department independent of the regimental medical officers be formed, that an additional surgeon be added to each regiment, and that the hospital corps consist of ten men to a regiment.

November Deaths.—During November 1,167 deaths were reported, 43 more than in the previous month, 84 more than in November, 1902, and 109 more than the average for the last ten Novembers. The death-rate was equivalent to an annual mortality of 15.1 per 1,000 for the large towns, 14.2 per 1,000 for the small towns, or 14.9 per 1,000 for the entire state. Deaths from infectious diseases were 236, or 20.2 per cent. of the total mortality.

ILLINOIS.

Student Dies.—Miss Caroline Beardsley, Highland Park, a student in the medical department of the University of Illinois, died suddenly from kidney disease, December 14.

New Buildings.—The building committee of the county board has decided to erect at Dunning a cottage for working patients and a new morgue and pathologic laboratory; and at the Cook County Hospital a children's building.

Appointments.—The Board of County Commissioners of Cook County has approved the appointment of Dr. Charles Whalen to the County Hospital, and the reappointment of Dr. Vaclav H. Podstata, as superintendent of the Cook County Institutions, Dunning, and of Dr. Warren H. Hunter as county physician.

Personal.—Dr. William J. Cheaney, Petersburg, has been appointed county physician of Menard County.——Dr. John T. Miller, Decatur, has been re-elected county physician of Macon County.——Dr. G. W. Rohr, Rockford, will be the guest of honor at the annual banquet of the Winnebago County Medical Society in February next.——Dr. Herman J. Huyett, Milan, is the dean of the profession of Rock Island County.——Dr. Frank B. Lucas, Peoria, has been elected county physician of Peoria County.

KENTUCKY.

District Physicians Elected.—Drs. Palmer G. Keeney, Edwin Wendt and Oscar A. Frickman have been elected district physicians of Newport.

Diphtheria and Smallpox.—Cave City reports 10 or 15 cases of smallpox, and at Richmond the public and private schools have been closed on account of the disease.——Diphtheria is said to be raging in Bellville, near Owensboro, and in the southern portion of Bracken County.

College Hospital Must Pay Taxes.—As a result of the decision by Judge Miller of the Jefferson Circuit Court, the hospital of the Kentucky School of Medicine must pay taxes. It was the contention of the college authorities that the hospital should be exempt because of the large number of charity patients cared for annually.

NEW YORK.

Smallpox.—The state health department reports on December 16 that smallpox was present at 12 places not noted in the report of December 5, when a list of 33 localities was published, in which smallpox existed.

Steel Company to Erect Hospital.—The Lackawanna Steel Company is about to erect in connection with the steel plant at Stony Point, a suburb of Buffalo, a hospital for the treatment of the maimed and wounded in their employ.

Dr. Chapin Sentenced.—On November 24, Dr. Henry W. Chapin, Findley Lake, convicted of having caused death by a criminal operation, was sentenced to imprisonment for a term of not less than one year, nor more than three years in the state penitentiary at Auburn.

Buffalo Deaths.—The monthly report of the department of health for November shows an annual death rate of 12 per 1,000. The principal causes of death were as follows: Consumption, 36; diphtheria, 11; typhoid fever, 8; debility, 28; alcoholism, 10; cancer, 22; apoplexy, 19; meningitis, 9; endocarditis, 7; vulvular heart disease, 25; pneumonia, 41; appendicitis, 6; cirrhosis of the liver, 6; gastritis, 8; gastroenteritis, 8; diabetes, 3; nephritis, 23; uremia, 5, and violence, 41. The total deaths for November were 438, as compared to 396 for November, 1902.

New York City.

Pneumonia and Tuberculosis.—The vital statistics for the year show 9,260 deaths from pneumonia, 13 per cent. of the total mortality, and 7,570 deaths from tuberculosis.

Alcohol and Opium Inebriety.—Dr. T. D. Crothers of Hartford, Conn., will deliver a course of four lectures on "Inebriety from Alcohol, Opium and Other Narcotics," at the New York School of Clinical Medicine, Jan. 5 and 6, 1904, to which the public is invited.

Gifts and Bequests.—President Abraham Abraham of the Jewish Hospital announced at a recent meeting that he had received a donation of $25,000 from an individual too modest to give his name, dependent on the raising of a similar sum within a year.——By the will of the late James Gracie, $5,000 is devised to the Orthopedic Hospital of Manhattan for the endowment of a bed, and $25,000 for the general endowment fund.

SOUTH DAKOTA.

Optician, Not Physician.—H. S. Fish, an optician of Sioux Falls, who was recently arrested on the charge of practicing medicine without a license, was discharged without trial, as it was shown that he had not violated the medical practice act.

Diphtheria.—The diphtheria epidemic at Parker is subsiding. Fourteen cases occurred, with three deaths. The quarantine against the city has been raised.——Diphtheria has appeared among the Indian children at the reservation day school at Ironwood Creek, Rosebud Agency, and the school has been closed.

Medical Society Elections.—The Watertown District Medical Society held its annual meeting in Watertown, December 8, and elected the following officers: President, Dr. Edwin T. Ramsey, Clark; vice-president, Dr. Oscar G. Frink, South Shore; secretary-treasurer, Dr. James B. Vaughan, Castlewood, and censors, Drs. Hans M. Finnerud, Henry H. Clark and Robert F. Campbell, all of Watertown. The next meeting will be held Feb. 9, 1904.——Mitchell District Medical Society met at Chamberlain, December 3, and elected the following officers: President, Dr. Wellington J. Mayhim; vice-president, Dr. Frederick Treon, Chamberlain; secretary, Dr. E. Frank Reamer, Mitchell; treasurer, Dr. William R. Ball, Mitchell; censor for the year, Dr. Thomas B. Smiley, Mount Vernon, and delegate to the state society, Dr. Roscoe H. Goodrich, Chamberlain.

TENNESSEE.

Banquet to Dr. Hill.—The Chattanooga Medical Association gave a banquet, November 6, in honor of Dr. T. S. Hill of Montgomery, Ala.

Smallpox.—Four new cases are reported in one family living near Mikle's Mill, Knox County.——Franklin reports 2 cases and has quarantine regulations in force.——Knox County has 15 cases under treatment at the isolation hospital.——From June 27 to the end of November there were 1,839 cases in the state, with 36 deaths. Hamilton County had 783 cases, and Knox County 186 cases.

Elections.—Henderson County Medical Society met at Lexington, December 1, elected Dr. James C. Stinson, Center Point, president; Dr. Daniel W. Bradfield, Poplar Spring, second vice-president, and James M. Arnold, Lexington, treasurer, and re-elected Dr. John H. Howard, Lexington, first vice-president; Dr. C. H. Johnston, Lexington, secretary, and Drs. John R. Muse, John L. Murray and R. H. Davidson, all of Lexington, censors.——At its December meeting the Jefferson County Medical Society elected the following officers: President, Dr. Isaac McC. Tittsworth, Jefferson City, president; Dr. Samuel W. Fain, Dandridge, vice-president; Dr. B. F. Brown, Mount Horeb, secretary, and Dr. Payne A. Tinsley, Dandridge, treasurer.

GENERAL.

Congress of Arts and Science of the St. Louis Exposition.—The following medical men of Europe have accepted an invitation to attend and take part in the above congress: T. Clifford Allbutt, Cambridge (internal medicine); Professor Richelot, Paris (gynecology); Sir Felix Semon, London (otology and laryngology); Sir Lauder Brunton, London (therapeutics); Major F. W. Ross, Liverpool (tropical medicine); Professor Theodor Escherisch, Vienna (pediatrics).

FOREIGN.

Celebration of the Decennial of the Roentgen Rays.—The tenth anniversary of the discovery of the Röntgen rays will be celebrated next spring at Berlin by a special Röntgen congress and exhibition, at which Röntgen will be the guest of honor. Further particulars may be learned by application to Dr. Immelmann, Lützowstr, 72 Berlin, W. Germany.

LONDON LETTER.

The Health of Bombay.

The annual report of the executive health officer for the year 1902 contains much information of interest. The statistics are based on the census return of 1901. The birth rate was 22.67 per 1,000 against 17.42 during 1901. The mortality from plague began its seasonal rise in January and reached its maximum on April 3 and then declined. There was a decrease in the number of deaths from plague in all communities except Europeans and negro Africans. From August the plague mortality rose gradually to the end of the year. The government has, after careful consideration, done away with the compulsory measures and introduced voluntary ones directing the health department to follow a persuasive policy. Inoculation is not in favor, the people of Bombay have lost all faith in its protective effects. During the year 288 deaths from smallpox occurred, as compared with 159 in 1901. The increase is accounted for by the number of unvaccinated people who went to Bombay from the Portugese territory and soon after arrival were found to be suffering from the disease. Four thousand, five hundred and eighteen deaths were due to fevers; the highest number, viz., 3,847, is attributed to remittent fever. This is 3,419 less than in the previous year and 1,938 less than the average of the preceding 5 years. To typhoid fever 89 deaths were ascribed, being 27 more than during the previous year and 42 more than the average of the last 5 years; 483 deaths were due to ague, and 190 more than the average of the last 5 years. The mortality from fever rose and fell with the mortality from plague. The divisional health officers instructed their staffs in the methods of distinguishing the various mosquitoes and larvæ and a list of places was made out where anopheles larvæ were found. The *Anopheles culicifacies* and *Alopeles Listoni* are said to be the only malaria-bearing mosquitoes known in Bombay at present. Advice is being given as to the best-known means of preventing the breeding of anopheles.

PARIS LETTER.

Congress of School Hygiene.

A congress was held in Paris, November 1, through the efforts of physicians and families, who are desirous of ameliorating the conditions of school life, and changing some of the methods followed in the interests of school hygiene. Dr. Legendre, who is deeply interested in all such questions, described the characteristics that a school physician should possess. It should be noted that every large school in France has a physician of its own, and Legendre would like to see the rôle of the latter made more important; he said the construction of a school should not be undertaken until a medical man has been consulted. Special rooms should be reserved for contagious diseases. All such diseases that are of parasitic origin, adenoids, eye or ear troubles, scoliosis, dental decay, various nervous diseases should be inquired into by the physician. A large number of cases of deficient intellectual development are due to ill health. The hours of study and recreation should be inquired into also.

Correspondence.

A New Operation for Retrodisplacements.

COLUMBUS, OHIO, Dec. 15, 1903.

To the Editor:—In a recent issue of THE JOURNAL you publish a brief abstract of a paper by Alexandroff describing "A new operation for retroflexion or retroversion." The operation is one which I have been doing for the past eight years, and which I have described or referred to during discussions in the Section on Obstetrics and Diseases of Women, first at the meeting at Philadelphia, again at Denver, and again at New Orleans. I have no doubt the work of Alexandroff is entirely independent of mine, at the same time I do not believe there can be any question as to the priority of the operation.

328 E. State Street. F. F. LAWRENCE.

Deaths.

Edward Fridenberg, M.D. College of Physicians and Surgeons, New York, 1878, a member of the American Medical Association; New York State Medical Association; American Laryngological, Rhinological and Otological Society; American Otological Society; New York Academy of Medicine; New York County Medical Society, New York Ophthalmological Society and New York Otological Society; ophthalmologic and aural surgeon to the German Hospital, president of the Harlem Medical Society, died from apoplexy at his residence in New York City, December 9, aged 48.

Israel B. Washburn, M.D. Rush Medical College, Chicago, 1861, of Rensselaer, Ind., one of the most prominent physicians of Northern Indiana, a member of the American Medical Association, Kankakee Valley Medical Society, a surgeon in the Civil War, and in 1872 a member of the state legislature, died at Valparaiso, Ind., from malignant disease of the liver, after a surgical operation, December 11, aged 65.

Hugh Burford, M.D. Savannah (Ga.) Medical College, 1879, a member of the American Medical Association, and the Medical Association of Georgia, acting assistant surgeon U. S. P. H. and M.-H. Service; surgeon for the Southern Railway, and member of the Association of Southern Railway Surgeons, died at his home in Brunswick, Ga., December 7.

Alfred H. Brundage, M.D. Albany (N. Y.) Medical College, 1856, a member of the American Medical Association, surgeon of the Thirty-second Ohio Volunteer Infantry in the Civil War, died at his home in Xenia, December 10, from uremia, after a short illness, aged 68.

Lewis A. Frost, M.D. Detroit Medical College, 1875, from 1881 to 1895, assistant physician at the Illinois Central Hospital for the Insane, Jacksonville, Ill., died at his home in that city, December 14, from paralysis, after an invalidism of five years, aged 61.

Elisha Hall Bridges, M.D. Bellevue Hospital Medical College, New York, 1866, for many years president of the St. Lawrence County Medical Society, died at his home in Ogdensburg, N. Y., October 9, from acute Bright's disease, aged 62.

Edward F. C. Rembe, M.D. St. Louis College of Physicians and Surgeons, 1891, of Lincoln, Ill., died at the Deaconess' Hospital in that city, December 14, after an illness of three weeks, from septicemia, aged 49.

Albert Moser, M.D. Harvard University Medical School, Boston, 1899, who served throughout the Spanish-American War in China and the Philippines, died at his home in Lima, December 9, aged 33.

Wilfred Stedman Fisher, M.D. University of Michigan, Ann Arbor, 1903, house surgeon at the University Hospital, Ann Arbor, died November 30 at Ann Arbor, from typhoid fever, aged 26.

Timothy O'Connor, M.D. College of Medicine and Surgery of the University of Minnesota, Minneapolis, 1890, of Maple Lake, Minn., died in Denver, from consumption, December 11, aged 45.

T. M. Gwin, M.D., assistant surgeon in the Confederate service during the Civil War, died at his home in Blacksburg, S. C., from dropsy, December 9, after a long illness, aged 64.

James L. Patty, M.D. Louisville Medical College, 1872, of Bigbee Valley, Miss., was found dead in his buggy, near Brooksville, Miss., December 12. Death was due to apoplexy.

Watkins W. Griffiths, M.D. University of Vermont, Burlington, 1895, of Hillsborough Bridge, N. H., died recently at the Margaret Pillsbury Hospital, Concord, N. H., aged 35.

Josiah W. Willis, M.D. Homeopathic Medical College of Missouri, St. Louis, 1875, died at his home in Galesburg, Ill., December 14, from paralysis, after a short illness, aged 68.

Earl Evans, M.D. Berkshire Medical College, Pittsfield, Mass., 1856, a member of the American Medical Association, died at his home in Winchester, N. H., November 28.

Henry P. Peebles, M.D. Miami Medical College, Cincinnati, 1873, formerly of New Castle, Pa., died at Chihuahua, Mexico, November 30, after a long illness, aged 51.

George A. Hollister, M.D. Ohio Medical University, Columbus, 1895, of Toledo, Ohio, died at Bellevue, Ohio, December 9, from general paresis, after a long illness.

George Horine, M.D. Kentucky School of Medicine, Louisville, 1879, died at his home in Americus, Ga., December 8, after a long illness from lung disease, aged 47.

George Horace Brown, M.D. University of Vermont, Burlington, 1882, died suddenly at his home in Gilmanton, N. H., December 5, from apoplexy, aged 50.

A. L. Kline, M.D. Louisville Medical College, 1874, died at his home in West Enterprise, Miss., December 12, after an illness of several months, aged 57.

Hugh P. Whiteside, M.D. Kentucky School of Medicine, Louisville, 1875, of Pe Ell, Wash., died recently from typhoid fever at the Centralia Hospital.

Cornelius M. O'Leary, M.D. New York University, of New York City, 1864, was killed by a motor train in Brooklyn, December 12, aged 64.

Charles B. Ridley, M.D. New Orleans School of Medicine, 1868, died at his home in La Grange, Ga., December 14, after a prolonged illness.

Sophronia Nichols, M.D. Boston University School of Medicine, 1874, died in Barona, Cal., after a long illness, November 12, aged 68.

Henry James Ward, M.D., of Coaling, Tuskaloosa County, Ala., died in Birmingham, Ala., December 13, from paralysis, aged 61.

John Taliaferro Jones, M.D., of Charlottesville, Va., died at his home in that city, December 10, after a brief illness, aged 78.

Samuel M. C. Hawthorne, M.D. Medical College of Alabama, Mobile, 1889, died at his home in Pineapple, Ala., December 9.

Fred J. Rothacher, M.D. Detroit College of Medicine, 1902, died suddenly in his office at Detroit, December 8, aged 36.

Edward A. Everitt, M.D. Albany (N. Y.) Medical College, 1856, died recently at his home in Burlington, Pa., aged 72.

Alvinzi G. Thomas, M.D. Atlanta Medical College, 1858, died at his home in West End, Atlanta, December 14, aged 70.

Otto Fuls, M.D. Miami Medical College, Cincinnati, 1870, died at his home in Cumminsville, Cincinnati, December 10.

Charles E. Stewart, M.D. Hahnemann Medical College, Chicago, 1878, died recently at his home in Streator, Ill.

N. B. Ridgway, M.D. Starling Medical College, Columbus, 1870, died at his home in Galion, Ohio, December 12.

Frank W. Burlingame, M.D. Homeopathic Hospital College, Cleveland, 1882, of McKeesport, Pa., died recently.

J. A. Williamson, M.D. Vanderbilt University, Nashville, 1884, died recently at his home in Newark, Ark.

Lincoln C. Sappington, M.D., died from hemorrhage at his home in St. Louis, December 14, aged 46.

Carlton D. Ashley, M.D., died at his home in Cleveland, Ohio, December 9, aged 81.

Medical Organization.

Indiana.

GENERAL REPORT.—Dr. Paul J. Barcus, Crawfordsville, councilor for the Ninth District, reports that all of the counties in his district have been reorganized and have adopted the new constitution and by-laws. Each of the societies has an increased membership, some having increased more than 100 per cent. during 1903. He says that he has visited nearly all of the societies, and that while some are not doing much at present, "there is a splendid prospect for a general revival of interest in all the counties of this district."

Maryland.

GENERAL REPORT.—Dr. Henry O. Reik, Baltimore, reports that the work of reorganization in Maryland is progressing steadily and satisfactorily; that twelve county societies have been organized during the past month. Since there are only twenty-four counties in Maryland, this report is very encouraging.

GARRETT COUNTY MEDICAL SOCIETY.—The physicians of Garrett County organized at Oakland, December 10, with the following officers: President, Dr. William H. Ravenscroft; vice-president, Dr. Henry W. McComas; secretary and treasurer, Dr. John E. Legge, all of Oakland, and censors, Drs. Mahlon C. Hinebaugh, Oakland, W. G. Drinkwater and H. R. Boyer.

DORCHESTER COUNTY MEDICAL SOCIETY.—The physicians of Dorchester County, Eastern Shore, organized a society at Cambridge, December 5, with the following officers: Dr. Benjamin L. Smith, Madison, president; Dr. Thomas H. Williams, Cambridge, vice-president; Dr. Guy Steele, Cambridge, secretary; Dr. John Mace, Cambridge, treasurer, and Drs. Robert J. Price, Vienna, Sidney A. Stokes, Cornersville, and Eldridge E. Wolff, Cambridge, censors.

North Carolina.

JACKSON COUNTY MEDICAL SOCIETY.—On November 18 the physicians of the county met at Dillsboro and organized on the standard plan with all the licensed physicians as charter members. Dr. J. M. Candler, Dillsboro, was elected president, and Dr. George P. Edwards, Sylva, secretary. A charter has been granted by the Medical Society of the State of North Carolina.

Therapeutics.

[Our readers are invited to send favorite prescriptions—such as have been tried and found useful—for publication in these columns. In each case the name of the sender must accompany the prescription, but the name will be published or omitted, as the sender may prefer.]

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Injection in Syphilis.

The following combination is recommended by Anthony in the treatment of syphilis:

R.	Hydrarg. biniodidi	gr. iss .	09
	Potass. iodidi	gr. ix	60
	Sodii phos.	gr. xv	1
	Aquæ destil.	ʒii	60
	Sol. sodii chloridi (decinormal)	ʒii	60

M. Sig.: Sixteen drops by hypodermic injection once daily

Caffein Hypodermically.

Caffein, according to *Merck's Archives,* is not suitable, as a rule, for hypodermic injection owing to its comparative insolubility—being soluble in not less than eighty parts of water. Its solubility is greatly increased by the addition of equal parts of sodium benzoate or sodium salicylate or perhaps antipyrin. The following combinations are consequently suitable for hypodermic use:

R.	Caffeinæ		
	Sodium salicylatis, āā	3i	4
	Aquæ destil.	3ii	8

M. Sig.: Five to ten drops hypodermically; or:

R.	Caffeinæ	3iii	12
	Sodii benzoatis	3ii	8
	Aquæ destil	3v	20

M. Sig.: Five to ten drops hypodermically.

Caffein in Alcoholic Toxemia.

Caffein is of value as a diuretic and in cases of venous congestion; it refreshes and stimulates the nervous system and is a vasomotor tonic. It is of great use in attacks of dyspnea caused by sclerosis of the coronary arteries, governing to some

extent the caliber of the blood vessels and so sustains the circulation. It increases the loss of carbon by the organism and does not restrain the loss of nitrogen. Caffein seems to take the place of alcohol and to quench the desire for it.

It is, therefore, of service, according to A. J. Hall in *Med. News*, in the treatment of alcoholic toxemia because it increases the kidney secretion, corrects the insomnia, corrects the defective circulation, stimulates the heart and promotes the elimination of the toxins.

Medicolegal.

Expert Evidence with Regard to Time of Death.—The Supreme Court of Utah holds, in the murder case of State vs. Mortensen, that there was no error in admitting the testimony of a physician relating to the probable length of time which intervened from the time the deceased had eaten his supper until his death, as indicated by the appearance of the contents of the stomach and the stage of digestion, the witness, as an expert, having made an examination of the stomach of the deceased.

Damages for Fracture of the Coccyx and a Sprain.—The United States District Court holds, in the case of the City of Portsmouth, a disembarking passenger having sprained her ankle and fractured the coccyx by falling between the boat and dock, that an award of $4,000 damages was only reasonable and would be allowed, medical experts having testified that the injuries sustained were all permanent in character, and that from same she would suffer all of her life, their tendency being to make her an invalid and a nervous wreck.

Physical Examinations in Oklahoma.—The Supreme Court of Oklahoma holds, in City of Kingfisher vs. Altizer, that the courts of that territory can not order a party bringing an action for an injury to the person to submit to a surgical examination in advance of or during the trial of the cause. It says that one may expose his body, if he chooses, with due regard to decency, and with the permission of the court; but he can not be compelled to do so in a civil action without his consent. Where a person unreasonably refuses to show his injuries when requested to do so, that fact may be considered by the jury as bearing on his good faith, as in any other case of a party declining to produce the best evidence in his power and under his control.

Furnishing of Medical Treatment by Employers.—The Court of Civil Appeals of Texas says, in Galveston, Harrisburg & San Antonio Railway Company vs. Hennigan, that while, independent of a contract, no duty rests on a master to furnish his servants with medical and surgical treatment, yet, if he undertakes to furnish such treatment, the law imposes on him the duty to use reasonable care in engaging the services of a competent and skillful physician and surgeon for that purpose. And if, through his failure so to do, the physician employed is incompetent and unskillful, and through such incompetency, etc., in the treatment of the servant injures him, the law holds the master responsible for his failure to discharge the aforesaid legal duty. Such liability is independent of any duty arising from a contract.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.

December 12.

1 *The Function of Maternal Milk in Developing the Stomach; a Factor Hitherto Overlooked in Artificial Infant Feeding. Henry Dwight Chapin.
2 *Cyclical Albuminuria. Arthur R. Elliott.
3 *Muscle Tonus and Tendon Phenomena. Joseph Fraenkel and Joseph Collins.
4 A Rare Case of Patent Diverticulum Ilei. August A. Strasser.
5 *The Treatment of Cancer by Caustic Paste. Charles W. Allen.

1. **Maternal Milk.**—Chapin reviews the comparative anatomy of the stomach and shows that infants and their mothers are adapted to each other functionally as well as anatomically. Cow's milk is what we have to use where mother's milk fails. As the proteid does not fit the baby's stomach it must be altered in some way or other. In the cow, digestion is principally gastric and food slowly leaves the stomach. Cow's milk curdles in large masses that can not readily pass onward, while human milk does not form solid curds. An alteration of this character of cow's milk may be brought about by various methods, one succeeding where another fails. He makes use of the alkalies, the dilution of cow's milk with the plain gruels and dextrinized gruels and points out that no one rule, but only a perfect adaptation to the condition of the individual infant can be followed. Experience and study will enable the infant feeder to do what nature does automatically.

2. **Cyclical Albuminuria.**—Elliott considers this anomaly an evidence of defective glomerular condition, a few leaky glomerules as yet imperfectly repaired, after some localized glomerulitis, permitting under the high interglomerular blood-pressure of the upright position the passage of albumin into the urine. Every cyclical albuminuria must be looked on as simply a phase or a mild degree of true nephritis which has preceded it. This may have been latent and escaped detection. The view does not necessarily imply a serious prognosis. The disease is not active and progressing, but tends to disappearance under proper care.

3. **Muscle Tonus and Tendon Phenomena.**—The conclusions of Fraenkel and Collins' studies are: 1. That disease of the posterior columns causes hypotonia and decrease of reflexes, and that the tendon phenomena are absent or diminished unless additional disease of the descending tracts counterbalance this influence. (Return of knee-jerks in cases of tabes after hemiplegic attacks.) 2. That disease of the pyramidal tracts causes hypertonia and increase of reflexes, including the tendon jerks unless additional disease of the ascending tracts, anterior horns or peripheral neurons, neutralizes this influence. 3. Histologic hypertonia and hypotonia modify the above-stated relations to a slight degree when the disease has not advanced to its full clinical representation. 4. There is a large group of more or less normotonic registrations found in their lists with approximately normal behavior of the tendon phenomena. 5. There is also a smaller group with more or less marked hypotonic registrations, the tendon phenomena being mostly diminished, not easily elicited, and the muscular contraction is sluggish and vermicular and quickly exhausted. This is not influenced by a well-executed reinforcement.

5. **Cancer.**—Allen objects to the statement by Campbell White that the caustic treatment of cancer has been rejected except by charlatans. He thinks Dr. White would not mean to class him among charlatans, though he still uses this method. In looking over his records he finds that the final results of the caustic treatment and of the *x*-ray are almost identical.

6 *The Relative Importance to the Community of Pneumonia and Tuberculosis. Arnold C. Klebs.
7 *Address on Hernia. John B. Deaver.
8 *Amputations. Thomas H. Manley.
9 Amyotrophic Lateral Sclerosis. Alexander McPhedran.
10 *Infections of the Knee-Joint. I. R. Trimble.
11 *Care of the Uterine Cervix. H. Wellington Yates.
12 The Brain of Children and Some Suggestions from the Standpoint of the Physician as to How It Should Be Regarded by the Teacher. Henry L. Swain.

6. **Pneumonia and Tuberculosis.**—Klebs' paper (which has been published in the *Illinois Medical Journal*, December, page 486) ends with the following conclusions:

1. The relative economic importance of pneumonia and tuberculosis can not be estimated by a mere comparison of total mortality figures for each disease.

2. The apparently high mortality figure and its increase of late, for pneumonia is produced by the enormous death rate and its increase attributed to this disease, in early childhood.

3. Therefore, the high mortality from pneumonia and to a certain extent its increase is due to a classification of different ill-defined pathologic conditions under one name, while that from tuberculosis represents that of a well-defined morbid entity.

4. For this reason and on account of the relative shortness of disabling sickness and frequent recovery in pneumonia, the great length of disabling sickness and infrequent recovery in tuberculosis, the relative importance of the two diseases is so vastly different, that a comparison on economic grounds reveals the overpowering danger from tuberculosis.

5. The steady decrease of the tuberculosis death rate can be explained on the grounds of increasing improvement of hygienic conditions in late years and as the result of specific prophylactic measures.

6. The increase of the pneumonia death rate occurring in a time of improving hygienic and sanitary conditions and of a general application of antiseptic principles, shows its independence of these features.

7. Therefore, and in view of the still enormous mortality from tuberculosis, its demonstrated preventability and the possibility of its arrest only in its earliest stages, the institution of educational measures in regard to personal and public hygiene widely and specifically applied, for the prevention of this disease, seems to be distinctly indicated.

8. Since for pneumonia, as pointed out by E. F. Wells, "the fundamental information on which prophylactic rules may be formulated is not yet at hand" this subject needs further investigation from a bacteriologic and epidemiologic standpoint as well, before "exaggerated and irrational notions in regard to its dangers and its avoidance" are communicated to the public, which in view of the facts given are out of all proportion.

7. **Hernia.**—Deaver's article is a general review, pointing out the methods he employs under various conditions.

8. **Amputations.**—Manley insists on the modern tendency to conservatism in amputations.

10. **Knee-Joint Infections.**—The points emphasized by Trimble are the need of careful diagnosis in every case of inflammation in or about the joint, and, when purulent inflammation is present, the early opening of the joint and means taken to prevent the formation of pockets of pus.

11. **Care of the Uterine Cervix.**—Yates insists on the importance of thorough excision of scars in trachelorrhaphy, not the mere denuding of the surfaces and suturing, but the complete removal of foreign tissues. We should be careful in ascribing symptoms to cervical laceration, for not all the reflex symptoms that occur can be properly so referred.

Medical News, New York.

December 12.

13 *The Home in Its Relation to the Tuberculosis Problem. William Osler.
14 *Syphilis and Divorce. Prince A. Morrow.
15 *Some Practical Suggestions on Physical Education in the Public Schools. Richard C. Newton.
16 *Report of Cases with Exhibition of Specimens Diagnosed by the Cystoscope. John R. Wathen.
17 *Hysteria. William B. Young.
18 *Enlarged Bronchial Glands. J. R. Clemens.
19 *A Humble Sterilizer. Douglas H. Stewart.

13.—See editorial last week.

14. **Syphilis and Divorce.**—Morrow gives a digest of the legal status of syphilis and divorce, and advises that under the present conditions of law, syphilis should never be invoked as the cause of action, unless it constitutes the chief or only phase of cruelty that can be alleged. The proceedings had better by far be based on charges of infidelity if they can be sustained. The inconveniences to the applicant to prove the facts for divorce are very serious and should be avoided if possible. Still there are many cases of marital infection of such aggravating character that it may be the only resource. There are so many loopholes of escape for the guilty party from the interpretation of what constitutes "willful and knowing" communication, and so many extenuating circumstances that may be pleaded, that the existing laws are not adequate. He would advise the physician not to appear in the interest of the patient, but let the proof of the communication of the disease be furnished by a medical expert appointed by the court, and especially, he says, should the attending physician avoid giving a letter or certificate as to the existence of syphilis in the plaintiff and his treatment of it. Certificates of this character are looked on with suspicion and may be rejected by the courts.

15. **Physical Education in Public Schools.**—Newton advocates dispensing with the teachers of superfluous and ornamental branches if necessary, using the money thus saved for hiring necessary medical inspectors and the obtaining of proper facilities, etc., for physical education. The evils of forcing children in schools in an ignorant way are hardly less, he thinks, than those of child labor.

16. **Cystoscopic Examinations.**—Five cases are reported to illustrate the necessity of cystoscopic examination, showing the morbid disease, calculus, foreign bodies, etc., in the bladder. Wathen insists on the importance of more thorough and accurate methods of diagnosis in this field.

17. **Hysteria.**—Young considers hysteria a psychosis due largely to the unconscious impressions of infancy and childhood in neurotic subjects. The pathology, he thinks, will be located in the adrenal system, and the treatment should be psychic. Suitable resorts should be erected for the poor. With such methods he believes hysteria would be on the decrease instead of on the increase. He accounts for the greater amount of hysteria among women than among men by the fact that female children are more under the influence of hysterical mothers than are boys.

18. **Enlarged Bronchial Glands.**—The importance of these glands, their frequent oversight and their potential toward tubercle and the danger of neglect are pointed out by Clemens.

19. **A Home-Made Sterilizer.**—Stewart suggests the use of an ordinary wash boiler. Through the flange of the boiler cover holes are punched, passing a string through each. To sterilize heavy bed linen, sheets, etc., make a criss-cross network over the fabrics after packing the cover in the inverted position; put the instruments in the boiler itself, covering with about six inches of water and add one heaping tablespoonful of washing soda, put on the cover, place the whole on a stove and boil hard for ten minutes. Then let the apparatus cool. He says there is a distinct advantage in commencing the operation with cold water and again gradually lowering the temperature after boiling. When the cover is finally lifted it is a sterile tray and should be stood bottom upward on a convenient table, the strings severed, and its contents be allowed to remain undisturbed until each is required. He suggests care in disinfecting oily instruments by boiling, as water covered with a layer of oil may be raised to about 120 C. when it begins to boil explosively; it is then safer to be out of doors than in the kitchen.

20 *General Peritonitis Complicating Scarlet Fever. John H. McCollom and John B. Blake.
21 Was He Insane? A Study in Mental Diagnosis. (To be continued.) C. A. Drew.
22 *A New Method of Closing the Abdomen After Laparotomy. Frank A. Higgins.
23 *Albuminuric Retinitis. Allen Greenwood.
24 As to Pope Leo's Case—Pleuro-Pneumonia. Samuel Delano.
25 Rupture of the Tendon of the Extensor Longus Pollicis; Tendon Transplantation. C. L. Scudder and W. E. Paul.

20. **Peritonitis Complicating Scarlet Fever.**—Two cases are reported by McCollom and Blake, who regard them as interesting on account of the fact that this complication is not referred to at any length in text-books. In both the peritonitis occurred late in the course of the scarlatina, due to streptococcus, and without any apparent local inciting cause. It seemed to be only a part of the widely distributed general infection involving other serous cavities, excretory organs, special sense organs and part of the circulatory system. The peritoneum, they think, was affected through the blood; there is no more obvious explanation. In the treatment palliative means may do if the signs of peritoneal infection are slight, but if the pulse rises, and pain, tenderness and spasm increase, drainage is imperative. The condition of the kidneys is the most definite contraindication to anesthesia, and whenever possible cocain should be substituted for ether. The operation should consist of a rapid celiotomy, thorough irrigation with hot salt solution and drainage. The incision should be in the middle line unless there are definite local symptoms. Hot moist dressings, frequently changed, are desirable. Salt solution hypodermically or by rectum, and water by the mouth if the patient does not vomit are indicated. Stimulation should be free. Alcohol may be contraindicated by the kidney condition. Caffein, strychnia and digitalis may be used energetically. The prognosis is always grave.

22. **Closure of Laparotomy Wounds.**—Higgins uses a thin metal strip or plate over which he ties his mass suture, this underlaid by an antiseptic gauze, with a small pad of the gauze inserted under each end, thus keeping out infection. He is now testing a glass plate through which the healing of the wound can be watched.

23. **Albuminuric Retinitis.**—Two groups of this condition are recognized by Greenwood, one including those cases where endarteritis of the chorioretinal vessels is largely a part of a general arterial degeneration of which the chronic interstitial nephritis is also only a part. These cases occur in the old and middle-aged. The second group includes those cases due to uremic poisoning of the blood from acute or chronic lesions of the kidney, usually parenchymatous or diffuse. They occur mostly in youth and early adult life, showing a greater retinal destruction with consequent greater impairment of vision. The prognosis is bad in all but the cases resulting from scarlet fever and pregnancy. In the first group the chances of life are rather better. He reports briefly a number of cases of each group and gives the results. Of the 16 cases of the first group, 4 died within a year, 4 within two years, 4 within three years, and 1 lived nearly four years. One was lost sight of. Of the 2 living patients neither dates back over two and a half years. Of the 10 cases of the second group, 4 died within eight months, 1 within two years, 1 after four years and seven months, and 1 was known to be alive two and a half years after first being seen. The 2 cases occurring from pregnancy recovered, and the tenth case has been lost sight of.

New York Medical Journal.

26 *The Administration of Antitoxin in Diphtheria by the Department of Health During 1902. J. S. Billings, Jr.
27 The Roentgen Rays in Therapeutics. Mihran K. Kassabian.
28 Report of a Case of Rupture of the Uterus in Which Hysterectomy Was Followed by Recovery. Francis T. Stewart.
29 Some of the More Infrequent Causes of Obstruction of the Common Bile Duct. Levi J. Hammond.
30 Dry Hot Air in the Treatment of Bright's Disease. (Concluded.) Clarence E. Skinner.
31 The Element of Faith in Healing. P. C. Kalloch.
32 A Case of Poisoning by Hyoscin Hydrobromate. Frederick Krauss.
33 The Treatment of Habitual Abortion. Anna S. Wilner, Frances Bradley and Eugene R. Corson.

26. **Diphtheria Antitoxin.**—Billings analyzes and tabulates the statistics of the use of diphtheria antitoxin by the health department of New York during the year 1902. In 15,792 cases injected, 1,860 died, a case fatality of 11.8 per cent.; 722 of these, however, were moribund when injected and deducting these reduces the mortality to 7.5 per cent. One fact brought out and especially emphasized in the report is the imperative necessity of the earliest possible administration of antitoxin. Of the 1,702 cases injected the first day of the disease, only 85 patients died, including the moribund cases, or less than 5 per cent.

Cincinnati Lancet-Clinic.

December 13.

34 Only a Step—Sanitation. H. H. Speers.
35 *Treatment of Lupus with Local Applications of Turpentine. W. S. Hoy.
36 Surgery of Prostate, Pancreas, Diaphragm, Spleen and Thyroid. (Continued.) B. Merrill Ricketts.

35. **Lupus.**—Hoy advocates the use of turpentine in lupus and reports three cases in his experience where it succeeded. The method was in keeping the ulcer more or less saturated with turpentine all the while. In all of the applications, picric acid gauze or cotton was used to keep the parts moistened with the turpentine.

FOREIGN.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures, single case reports and trials of new drugs and artificial foods are omitted unless of exceptional general interest.

Deutsche medicinische Wochenschrift, Berlin and Leipsic.

1 (XXIX, No. 48.) *Zur Behandlung der akuten Mittelohrentzündung (otitis media). Heine (Lucae's clinic, Berlin).
2 *Zur Frage der Indikation und des Erfolges der Talma'schen Operation bei der atrophischen Leber-Cirrhose. R. Lenzmann.
3 Lubarsch's Technic of Rapid Hardening and Embedding. O. Lubarsch (Posen).—Ueber meine Schnellhärtungs- und Schnelleinbettungsmethode.
4 *Zur Aetiologie der Endometritis exfoliativa. S. Gottschalk.
5 *Attempt to Produce an Antibody with Aid of Blood Serum of Cancer Subjects. C. S. Engel (Berlin).—Ueber einen Versuch, mit hilfe des Blutserums Carcinomatöser einen Antikörper herzustellen.
6 Adrenalin in Severe Hemorrhage. R. Kirch.—Ueber Adrenalin und seine Anwendung bei schweren Blutungen.
7 Physiologic Requisites for a Comfortable Reclining Position. T. Schrohe.—Ueber die phys. Bedingungen einer bequemen Ruhelage.
8 Ankylostomiasis in Dortmund. G. Helmann (Berlin).—Das Auftreten der Wurmkrankheit im Oberbergamtsbezirk Dortmund.
9 Das Honorar der Spezial-Aerzte.

1. **Acute Otitis Media.**—Heine describes the principles that prevail at Lucae's clinic in the treatment of this affection. Rest and application of warmth are first advised when there is little if any pain and no fever, and also sometimes in the case of children when an exudate in the middle ear may be assumed, but the color and general aspect of the tympanum indicate that the exudate is serous. Paracentesis is done at once when the pains are very intense and interfere with sleep at night, or even in the absence of intense spontaneous pain when the mastoid process is sensitive to pressure. Paracentesis is of course indicated at once on the first suspicion of meningeal inflammation. He reports a case in which the patient died five weeks after the commencement of a sudden and acute otitis media. He was a healthy young workman, and he continued at work for three weeks before seeking a physician. The necropsy showed recent basilar meningitis originating in the ear trouble. The suppuration in the middle ear had been unable to force a way out through the peculiarly thick tympanum and had penetrated through the oval fenestra into the labyrinth. Paracentesis in time would have undoubtedly saved this patient's life, but after the third week the damage had already been done.

2. **Talma's Operation in Atrophic Cirrhosis of the Liver.**—Lenzmann adds another to the list of entirely successful operations of this class. From his experience and that of others he advocates the operation in every case of atrophic cirrhosis of the liver when the organ is not yet perceptibly shrunken, but the signs of congestion in the portal vein, development of ascites, etc., are noticeable. Also when the liver is somewhat shriveled and there is more or less ascites, but the liver tissue is still functioning to a certain extent, as shown by the absence or slight degree of icterus. On the other hand, he thinks there is little prospect of success when the icterus is pronounced or when there is urobilinuria or when hemorrhages from the mucosæ, delirium, etc., indicate complete or considerable insufficiency of the liver function responsible for the production of bile. The heart action must still be good to insure the development of collateral circulation.

4. **Etiology of Exfoliating Endometritis.**—Gottschalk describes a case in which he discovered numerous thrombi in the veins of the uterine mucosa. The membranes had become detached from their foundation by a dissecting effusion of blood, the same as in premature detachment of the placenta. The thrombi were evidently due to stagnation of the blood from weak heart action. No micro-organisms were found in the tissues. The findings in this case suggest that the routine method of treatment by abrasio is irrational.

5. **Serum Treatment of Cancer.**—Engel drew 10 to 15 c.c. of blood twice a week from each of two subjects with inoperable cancer of the stomach or esophagus and injected the serum into rabbits. His aim was to induce the production of antibodies without antialexins. To eliminate the alexins the serum was heated to 58 C. before injecting. He describes his tests of the rabbit serum thus produced. It was injected into the cancer subjects with a further supply of alexins in the form of normal serum from healthy human subjects. Tests of the serum *in vitro* indicated that antibodies had been generated in the serum of one of the rabbits, while the tests were negative with the serum from another rabbit. One of the cancer subjects showed considerable improvement after this serum treatment and became able to swallow solid foods previously impossible. He returned twice a week for the withdrawal of blood and injection of the prepared serum, but the disease continued its course, and he died in less than four months. The other patient showed no improvement and died in a little more than two months. Engel thinks that serumtherapy founded on injections of cancer tissue is more promising than that founded on injections of serum. Further researches at present under way indicate that the prospects are much better for the production of an effective animal serum by injection of human blood serum from subjects with constitutional diseases other than cancer.

GENERAL INDEX.

Use of the index will be facilitated by bearing in mind that subjects are frequently given under two or more headings, e. g., brain, cerebral, tumors, etc.; heart and cardiac; cirrhosis, liver and hepatic; child, children and infant; gland, thyroid, etc. Often, too, writers treat of the eye, ear, nose and throat under one title, and the titles do not always permit of indexing under the several headings. The "General Index" contains only titles of articles and the *subjects* of: editorials, society proceedings, abstracts, medicolegal, and miscellaneous matter appearing in THE JOURNAL; the titles of: "Editorials," "Book Notices," "Deaths," "Societies," "Association News," and "State Boards of Registration" are indexed and arranged under their separate headings in the "Index of Departments," instead of in the body of the "General Index." The "General Index" contains the subjects of articles in other journals which have been abstracted in THE JOURNAL. The titles and authors of all other articles from other journals are under the "Current Medical Literature Index."

THERAPEUTICS.

Acne, 127, 513, 874
Adenitis, tuberculous, 1555
Adrenalin and atropin, 1294
Alcoholic excess, 1431
Alkalies in atony of stomach, 572
for relieving pain, 983
Alkalinity of urine, to reduce, 1294
Anal fissure, 628
Anesthesia, local, 627
Antiseptic and cleansing sprays, 1431
Antisepsis of mouth, 513
Aperient for pregnant women, 202
Argyrol in gonorrhea, 1293
Arterial tension, high, 1362
Arteriosclerosis, cerebral, 875
Arthritis, gonorrheal, 201
Aspirin, toxic symptoms of, 1555
Atony of stomach, alkalies in, 572
Baldness, prophylaxis and treatment of, 330
Barber's itch, 1430
Bedbugs, to kill, 1362, 1494
Benzoin preparations, 803
Bromipin by the bowel, 982
Bronchitis, chronic, 331, 513
Burns, 1494
Caffein hypodermically, 1581
in alcoholic toxemia, 1581
Calcium chlorid as a hemostatic, 1042
Cancer, 628
Chapped hands, 1363
Chloroform as a teniafuge, 681, 1555
Chlorosis with phlebitis, 331
Cholera infantum, sulphocarbolate of zinc in, 127, 1225
Chorea, 54, 875, 1161
Coma, diabetic, 331
Constipation, chronic, and hemorrhoids, rectal dilatation for, 803
Copper arsenite in enteric diseases, 573
Coryza, 466
Cough in pneumonia, 1109
syrup, a good, 1362
treatment of, 513
Croup, spasmodic, 1363
Cystitis, 1109
Delirium tremens, 1226
Diabetes, uranium nitrate in, 1109
Diarrhea, 127, 388, 804
in typhoid fever, 1494
methylene blue in, 1494
Digitalis, administration of, 1431
leaves, variation in strength of, 513
Diphtheria, 1494
Dipsomania, 573
Drug eruptions, 875
Dysentery, 332
Dysmenorrhea, 446, 927
Dyspnea in chronic bronchitis, 513
Eczema, 741, 1363
of the eyelids, 1430
Empyroform in diseases of the skin, 573
Enteritis, mucomembranous, 681
Enuresis, 275
Epicarin in tinea tonsurans and circinata, 688
Epilepsy, 1494
Epistaxis, 1294
Erysipelas, 628, 1161, 1225
Eye bruises, 1161
Formaldehyd in acute tonsilitis, 466
Formalin, inhalations of, 1554
Furuncles, 387, 573, 927
Furunculosis, 1430
Gastric secretion, disturbances in, 331
Gastroenteritis of nurslings, acute, 1109
Gastrointestinal atony, 275
Gelatin, administration of, 983
Glycoheroin for cough, 681
Goiter, exophthalmic, injections of iodo-ether in, 1294
Gonorrhea, acute, treatment of, 1554
Gonorrhea, treatment of, 1160, 1293
Headache, 332
Heart tonics, employment of, before an anesthetic, 1295
Hemorrhages in typhoid fever, 1554
Hemorrhoids, 572
Hyperchlorhydria, medicinal treatment of, 387
Hyperidrosis, local, 682
Ichthyol in chronic bronchitis, 331
Insanity, puerperal, 1160
Intolerance of milk, 275
Iodo-ether in exophthalmic goiter, injections of, 1294
La grippe, 1363
Laxative combinations, 874
Lead colic, 1160
Lecithin in tuberculosis, 331
Leg ulcers, 926
Lichen pilaris, 1109
Lumbago, 1494
Menstruation, painful, 573
Menthol, aqueous preparations of, 1295
Methylene blue in diarrhea, 1494
Mercury, hypodermically, 466
Migraine, 513, 1161
Milk, intolerance of, 275
Mouth, antisepsis of, 513
Neuralgia, trigeminal, 984
Neurasthenia, 127
gastric, 1431
Night sweats, 387, 681
Nitrites and nitroglycerin, 54
Oculist's practice, new remedies in, 1493
Ointment of adrenalin, 388
Opium habit, 513
Otitis media, chronic purulent, 874, 1225
Ozena, 201
Pertussis, 202, 276
Pharyngitis, chronic, 927, 1494
Phlegmasia alba dolens, 465
Phosphaturia, 1042
Phthisis, symptomatic treatment of, 1294
Pneumonia, 1554
Pruritus, 983, 1161
Rectal dilatation for chronic constipation and hemorrhoids, 803
Rheumatism, 275, 387, 1043, 1161
Ringworm, 387
Round worms (ascarides), 573
Salicylic acid externally in rheumatism, 331
Scalp wounds, treatment of, 276
Scrofula, sodium chlorid in, 983
Seborrhea of scalp, 804
Sodium cacodylate, 388
chlorid in scrofula, 983
Stomach, ulcer of, 513
Stye, treatment of, 1108
Sulphocarbolate of zinc in cholera infantum, 127
Sunburn and prickly heat, 681
Suprarenal extract in diseases of the skin, 465
Sweating of the feet, 1109
Syphilis, injection in, 1581
Syrup of iodid of iron, 1042, 1363
Tabes and neuritis, pains of, 1363
Terpin hydrate, 1042
Tonic for children, a, 1363
Toxemia, alcoholic, caffein in, 1581
Trachoma, 276
Tuberculosis, laryngeal, 983
Turpentine in pneumonia, 741
Ulcer, gastric, 1042
Uranium nitrate in diabetes, 1109
Uremic dyspnea, 1363
Urotropin, toxic action of, 1108
Urticaria, 202, 628
Vaginal douche, the 1363
Valerian, 741
in tuberculosis, 983
Vomiting during the administration of chloroform, 1431
Whitehead's treatment of gonorrhea, 1293
X-ray burns, acute, 572
Zinc sulphocarbolate in cholera infantum, 1225

CURRENT MEDICAL LITERATURE

INDEX OF TITLES

Explanation: This index includes the titles and the subjects of original articles published in the leading medical journals of the world during the past six months. The titles and the names of the journals in which they appeared were published weekly in the Current Medical Literature department, to which references are made. The figures in parentheses refer to the paragraph; the number following, to the page in THE JOURNAL. For instance, "Abdomen after laparotomy, new method of closing, (22) 1583," refers to page 1583 of THE JOURNAL, on which is found, opposite paragraph 22, the title of paper and name of author, viz., "A New Method of Closing the Abdomen after Laparotomy. Frank A. Higgins." This title is listed under the journal in which the article appeared: "Boston Medical and Surgical Journal, December 10." Titles of articles which appeared in THE JOURNAL are indicated in the index below by an asterisk (*) before the page number.

Abdomen after laparotomy, new method of closing, (22) 1583
importance of physical examination of, as routine procedure, (3) 1296
precision in diagnosis of surgical lesions in right half of, (98) 1502
stab and bullet wounds of, (95) 755
upper, plea for accurate diagnosis in diseases of, (124) 1050, (58) 1167
vocal fremitus of, (46) 1505
Abdominal auscultation, note on, (47) 686
closures, 1,000, by new method, (54) 1436
contusions, principles for treatment of, (132) 68
diseases, surgical treatment of, (60) 933
gestation, secondary, in rabbit, (64) 1172
gynecological operations, history of, (130) 528
massage, (105) 1057
muscles, congenital defects in, (81) 754
operations, (101) 1049
pain, causes of, in healthy, (4) 469
pain in pleurisy and pneumonia, *535
pulsation for diagnosis, case of, (72½) 1168
section for emergencies during pregnancy, cases of, (23) 1052
sections, observations on eighteen, (28) 685
sections, report of seven rare, (45) 1367
surgery, brief experience in, (15) 1504
surgery, evolution of, from personal reminiscences, (3, 6) 524
surgery, Fowler's position in, (6) 389
surgery in private practice, (80) 339
surgery, personal experiences in, (41) 1435
surgery, rubber-jawed instrument for, *1091
surgery, ten years of, by I. Tansini, (96) 942
surgery, timeliness in, (32) 745
surgical diseases, some points in, (13) 884
tumor, diagnosis of, (79) 471
wall, improved filigree for repair of defects of, (34) 392
wounds, including hernia, deviation from usual methods of closing, *904
Aberrant tissue from prostate, (64) 288
Abortion and premature labor, some indications for inducing, (41) 686
attitude of profession toward, (105) 339
bacillus, (96) 66
criminal, Colorado laws relating to, (104) 339
criminal, practical working of law against, (107) 339
Abortion, criminal, remedies for, (106) 339
habitual, treatment of, (33) 1584
hemorrhage, (151) 1371
histologic diagnosis of, (110) 1378
suggested amendments to law concerning, (108) 339
treatment of, (103) 688, (97) 1056, (108) 1117, (92) 1377 (45) 1505
unusual causes of (92) 1445
Abscess, cerebral, case of, (117) 637
cerebellar, mastoid disease and, (23) 1498
diagnosed as brain tumor, (151) 689
double mammary, (134) 1117
hyphophosphites in treatment of, (43) 1435
in liver, method of reaching, (26) 639
of cerebellum, diagnosis and treatment of, (81) 1565
of left temporosphenoidal lobe, of otitic origin, (10) 743
of the spleen, *304, (75) 471
production, artificial, in intoxications, (53) 64
suburethral, or incomplete internal urethral fistula, (41) 807
Abscesses, modern non-surgical treatment of, (159) 1371
Absorption and elimination, (127) 284
Acanthosis nigricans, (92) 1056
Accessorius, paralysis of, in tabes, (58) 1442
Accessory cavities, protection of, against bacterial invasion by ciliary movements, (71) 290
Accidents and neuropathology, relations between, (85) 400
Accommodation in man, mechanism of, (16) 991, (101) 1370
Accouchement forcé, (45) 519
Acetanilid poisoning, chronic cyanosis from, (29) 1559
Acetone and diacetic acid as cause of persistent recurring vomiting in children, (63) 520
Acetozone poisoning after application of a celluloid cast, (78) 994
Achilles-jerk and the front-tap, contribution to study of, (49) 58
Achylia gastrica and pernicious anemia, (73) 692
Acne rosacea, practical management of, (144) 62
vulgaris, (137) 210
æ-ray treatment of, (79) 339
Acoin cocain for local anesthesia, (101) 755
in surgery, (81) 1506
Aconite and veratrum viride, limitations in use of, *1459
Aconitum napellus, (131) 1371
Acoustic speech center, inhibiting function of, (92) 1121
Acquired characters, impressions of non-heredity of, (20) 57
Acromegaly, (7) 396, (92) 995, (7) 1503
chemical pathology of, (59) 58
Acroparesthesia, vascular and toxic, (17) 64
Actinomyces in sections, staining of, (103) 66
Actinomycosis, (29) 937
and the vermiform appendix, (55) 1171
at Tübingen, results of treatment of, (37) 1236
cases, (78, 79) 65, (29) 639, (45) 753, (73) 754, (88) 818
human, in France and elsewhere, (19) 397
in man, method of infection of, (61) 809
Adams-Stokes disease, new phenomenon in case of, (109) 643
syndrome, case of, (1) 743
Addison's disease, results of organotherapy in, (19) 1118
Address, Alumni Assn. Cent. Coll. P. and S., (112) 1117
Amer. Assn. Obst. and Gynec., (160) 1371
Amer. Elect.-ther. Assn., (122) 1303
Amer. Laryng. Rhin. and Otol. Soc., (69) 746, (97) 990
Amer. Med.-Psych. Assn., (81) 284, (43) 808
Amer. Neur. Assn., (47) 58
Assn. Med. Officers Army and Navy of Confederacy, (102) 210
Brit. Med. Assn., (1) 523
at inauguration of monument to Charcot, (44) 1563
Brit. Columbia Med. Assn., (90) 1561
by W. W. Keen on receiving degree of LL.D., from Univ. of Toronto, (121) 1371
Canadian Med. Assn., (123) 935, (124) 990
Eastern Ore. Dist. Med. Soc., (136) 1050
Graduates of Agnew Sanitarium, (135) 812
Ill. State Med. Soc., (68) 59
in medicine, (108) 1233
Jackson Co. Med. Soc., (113) 1371
Jenner Med. Coll., (137) 750
London School of Med. for Women, (20) 1052
Med. and Chirurg. Faculty of Md., (8) 1228
Med. Assn. Ind. Terr., (124) 812
Med. Assn. of Ala., (179) 936
Med. Dept. Univ. of Louisville, (40) 1046
Med. Soc. of Co. of Albany, (49) 1560
Med. Soc. of N. C., (151) 211
Med. Soc. of Penn., (102) 1233
Med. Soc. of Va. (116) 990
Med. Soc. of Va., (116) 990
Med.-Chirurg. Coll., (139) 1168
Med.-Chirurg. Soc., (31) 336
Neb. Med. Assn., (136) 210
N. Y. State Med. Assn., (155) 62, (59) 1501
Ohio Med. Assn., (26) 57
Ontario Med. Assn., (146) 211, (110, 129) 284
Pediatric Clinic, (50) 1505
Address, Rocky Mt. Interstate Med. Assn., (44) 1231
School of Pharmacy, (21) 1052
South Australian Branch of Brit. Med. Assn., (24) 690
State Soc. Iowa Med. Women, (84) 687
to Nurses of Lakeside Hosp., (22) 1366
Toronto Gen. Hosp. Training Sch. for Nurses, (100) 1561
Tri-State Med. Soc., (112) 61, (115) 523
Tri-State Med. Soc. of Ia., Ill. and Mo., (1) 1162
Univ. of Toronto, (86) 1502
Wash. State Med. Assn., (86) 1049
Wis. Med. Soc., (161) 750
Adenitis and arthritis, tubercular, light treatment of, (60) 1563
cervical, due to tonsillar infection, treatment of, (15) 1497
Adenocarcinoma of liver in childhood, (114) 1439
of nose, case, (73) 1232
Adenocarcinomata, relation, to atrophic scirrhus of breast, (87) 934
Adenocystoma, papillary, of thyroid and accessory thyroid glands, (26) 1559
Adenoid deafness, insufficiency of stenosal theory of (8) 1303
growths, (40) 1499
Adenoids, (38) 132, (118) 396, (168) 750, (11) 883, (33) 1170, (87, 123) 1233
adrenalin chlorid in operation, (110) 637
and thorax deformities, connection between, (89) 526
as cause of enlarged tonsils, etc., (42) 988
dangers of, (146) 750
in relation to audition and cerebration, (15) 576
relation to deaf-mutism, (28) 336
Adenoma, circumscribed sebaceous, (39) 992
of liver with cirrhosis, solitary, (59) 526
of thyroid, (125) 1168
Adenomata, ovarian, etiology of, (119) 1508
Adenomyoma of uterus, (70) 642, (48) 1053
of uterus, unrecognized form, with critical discussion of the Urnieren hypothesis of Von Recklinghausen, (124) 1508
pyloric, (31) 470
Adenotome, modified, (80) 1308
Adiposis dolorosa, (98) 1439
dolorosa with report of case, (116) 1439
dolorosa in boy, (112) 1123
Adnexa, conservative surgery of, (37) 398
experiences in treatment of suppurative affections of, and of pelvic connective tissue, (38) 885
ocular, traumatic lesions of, *959

Adnexitis, clinical treatment of (109) 1378
Adrenal extract, urticaria after nasal use of, (56) 1441
sufficiency, longevity a question of, (92) 990
Adrenalin and local anesthesia, (61) 641
chlorid and hydrochlorate of cocain in dentistry, (81) 1233
chlorid in asthmatic attacks, (19) 1164
chlorid in snake bite, (154) 1050
chlorid, physiologic action of, (78) 209
in anesthetizing the tissues, (56) 492
in eye, ear and nose work, (34) 280
in gynecology, (35) 814
in ophthalmology, (28) 1305
in severe hemorrhage, (6) 1584
in spinal cocainization, (100) 755
in surgical shock, (20) 1434
internal administration of, for control of hemorrhage, (63) 1167
action of on living organism, (98) 819
Adrenalized vaselin, (58) 64
Adrenals containing cells resembling those of liver, (94) 637
Adulterated and unhealthy foods, tests of, (55) 691
Age of man, the normal, (88) 811
Aerogenes capsulatus infection of neck, case of *1009
Aerztetag, XXXI deutsche, (63) 1120
Afterbirth, abnormal site of, (38) 1441
Agglutinating and bacteriolytic effect exerted by the sera of patients suffering from or preventively inoculated against typhoid fever, Malta fever and tuberculous affections, testing of, (16) 470
Agglutination of blood, (64) 585
Agglutinins, influencing of, by specific absorption, (85) 343
non-identity of, acting on flagella and body of bacteria, (103) 749
Agricultural implements, wounds inflicted by, (111) 61
Air, dry superheated, in treatment of septic infection, (19) 279
in veins during operations, (25) 1235
passages, non-tubercular hemorrhages of, *1462
Akatama, observations on, a West Central African disease, (24) 885
Albargin in treatment of gonorrheal vulvovaginitis in children, (150) 1510
Albumin and casts in surgical patients, significance of (21) 806
diet, (94) 1378
for subcutaneous feeding, (50) 1441
in urine, significance of, (179) 813
in urine, formaldehyd test for, (88) 1239
insoluble, from albumose during gastric digestion (140) 758
metabolism in anemia, (134) 143
"Albuminoids," conception of, (84) 343
Albuminous foods, new method of preparing, (94) 400
Albuminuria, (152) 1510
alimentary, (68) 1238
as accompaniment of diabetes mellitus, (17) 1562
clinical importance of, (2) 333
cyclical, (2) 1582
curable, (20) 937
cyclic, dependence of, on circulation, (98) 888
functional, (130) 1168
in diabetes mellitus, *354
orthostatic, (53) 634, (91) 934, (51) 1441
significance of, (126) 63 7
significance of intermittent, in life insurance work, (77) 1561
so-called febrile (112) 1508
value of, in differentiating pyelitis from cystitis, (24) 1113
Albuminuria with insufficiency of aortic valve, (129) 695
Albumose in feces, determination of, (77) 692
Albumosuria, experimental, (63) 887
Alcohol, (104) 210, (143) 211
and muscular effort, (134) 529
and public health, (58) 580
as therapeutic agent, (99) 688, (63) 817
compress treatment, modified, (83) 526
demonstrated pathologic changes from, *1383
human evolution with special reference to, (12) 1051
in alimentation, (22) 937
in disease, action of, especially in circulation, (2) 389, (8) 390
in relation to mental disorders, (11) 1051
influence of on size of heart, (70) 1238
legitimate therapeutic uses of, *1385
physiologic action of, (123) 528
physiologic and therapeutic actions of, (60) 1501
subjects refractory to, (36) 752
vapor, disinfecting properties of, (104) 1240
Alcoholics, present status of, (148) 812
Alcoholism and alcoholic insanity, boundary line between, (49) 988
and beer, (98) 755
changes in spinal cord, in chronic, (122) 143
crime and insanity, correlation of, (10) 56, (60) 580
in women, (10) 390
in working classes in Stockholm, (123) 1123
infantile, (59) 580
national congress against, (24) 1440
social factors that tend to degeneration of race and, (96) 990
Alexander's operation, (23) 524, (52) 1300
Alexins, origin and composition of, (50) 1374
plurality of, (26) 752
Alga study of physiology of, (28) 752
Alienists and neurologists, report of French Congress of, (70) 692
Alkalies, influence of, on experimental infections, (108) 1122
Alkalinity of blood, (159) 347, (32) 814
of blood in leucocytosis and infections, (117) 1057
of certain bacterial filtrates, connection between and their hemolytic power, (99) 749
Alkaptonuria, (75) 1442
Allantois, embryologic study of formation of, (49) 584
Alopecia areata, histologic studies on the action of chrysarobin in, (108) 890
from use of thallium, (45) 1441
of dental origin, cases of, (191) 70
Altitude on heart disease, influence of, (2) 515
relation of neuralgia to, (76) 989
treatment, who may benefit by, (6) 1432
Amber yellow glass in examination and treatment of eyes, (11) 631
Amblyopia, hysterical, cured by hypnotism, (96) 1378
Amebic enteritis, (115) 401
Amenorrhea, usually unrecognized cause of, (114) 1168
Amentia, (3) 813
America, letter from, (57) 64, (61, 63, 65) 65, (57, 59) 213, (52) 1171, (29) 1236, (40) 1305, (58, 63) 1563
American Med. Assn., some random comments on, (121) 210
medicine, progress of, and its relation to public affairs, *1379
Pediat. Soc., review of work of, (78) 59
Pediatrics before 1800, history of, (137) 403
American university, relation of, to professional schools, (104) 1050
Ammonia elimination in human urine, (64) 1442
Amnesic aphasia, abscess presenting symptoms of, (9) 937
state, homicide committed while in, (61) 338
"Amorphous agglutination," a peculiar sero-diagnostic phenomenon in "Friedlander" reconvalescent serum, (123) 757
Amputating in presence of suppuration, gangrene or mortification, (28) 1230
necessity of shortening large nerves when, (6) 340
Amputation after traumatisms, (120) 284
in diseases of women, (82) 1561
of both thighs for gangrene, recovery after, (120) 1567
technic of, (141) 135, (82) 581
Amputations, (8) 1582
Amyloid kidney, clinical studies of, (109) 1057
tumors, multiple, of larynx and lungs, (32) 1504
Anaërobe cultures, apparatus for, (87) 290
Anaërobic bacteria in intestinal affections, (71) 1055
Anal and rectal diseases treated without general anesthesia (31) 132, (147) 750
Analgesia, local, improvements in method of, (12) 469
Anastomosis formation of vas deferens after resection of epididymis, experimental studies of, (46) 886
internal, simple method of, (89) 990
intestinal, by elastic ligature, (77) 1048
intestinal, for prolapsed small intestine, (10) 689
intestinal, practical consideration of, (7) 985
intestinal, recent methods of, (21) 279
omental, for establishing collateral circulation of portal blood, (90) 990
portal, anatomy of, (2) 203
Anastomotic circulation of heart, (107) 527
specimens, preservation of, (21) 137, (105) 1445, (34) 1504
table, an adjustable (56) 58
Anatomy, clinical, problems of, (6) 468
instruction in, (145) 758
of some of lower species compared with that of man, differential characteristics in, (153) 62
Anchylostoma anemia, (105) 643
And then, (55) 208
Anemia, albumin metabolism in, (134) 143
Biermer's progressive, symptoms and pathology of, (67) 1376
fatty degenerative changes in, an attempt of nature to nourish patient, (57) 1501
in disease of women, (82) 1561
infantile postvaccination, (76) 585
idiopathic pernicious, (68) 343
infantum pseudoleukemica (89) 1439, (38) 1499
pernicious, (111) 210, (72) 988
pernicious, conditions that simulate, (1) 1439
pernicious, following parturition, (7) 582
pernicious, with marked ptosis of abdominal viscera, (7) 278
splenic, (18) 884, (119) 997, (49) 1505
splenic, discussion on pathology of, (4) 883
splenic, malignant disease following, (11) 937
Anemias of infancy, the, (11) 1504
secondary, organic iron medication in, (69) 1502
Anemic conditions, practical experiments in treatment of, (133) 396, (153) 637, (125) 1050
Anesthesia and anesthetics, (92) 395, (115) 750, (173) 936
Anesthesia by conduction, (43) 1374
consideration of general, with presentation of instruments, (25) 1434
general surgical, *1398, *1465
of upper air passages in tuberculous cases, (103) 1508
on body temperature, effects of, (80) 1048, (30) 1236, (47) 1367
pulmonary, (66) 988
with reference to Schleich principle, (106) 883
Anesthesin hydrochlorate for local anesthesia, (60) 1505
Anesthetic in children, selection of, (17) 986
in ophthalmology, choice of general, (37) 987
method of administration of, in Brooklyn hospitals, (73) 1048
personal experience regarding, (5) 683
precautions to be observed in selection of, (147) 1050
recent work in field of, (7) 813
selection of, (2) 277
some experiences with local and general, (101) 522
Anesthetist relation of, to patient and surgeon, (26) 633
Anesthol, (78) 642
advantages of, for making frozen sections, (58) 342
Aneurism, arteriovenous traumatic, cases of, (60) 470
etiology and pathologic anatomy of, (120) 750, (131) 1117
extracranial, of carotid, (76) 1565
femoral, (128) 210
fusiform, case of, treated by Matas' operation, (61) 1300
gelatin treatment in, (15) 340, (122) 750, (145) 812
of abdominal aorta treated by introduction of silver wire, (10) 937
of aorta, (35) 579, (86) 586, (99) 819
of aorta, Brazilian method of treating, (104) 1310
of aorta, Oliver's sign in, (103) 1057
of arteria carotis cerebri, (46) 1299
of external iliac artery, treatment of, by digital compression, (63) 1300
of gluteal artery, traumatic, treated by incision of sac and ligature of artery during intraperitoneal compression of internal iliac, (16) 752
of hepatic artery, (85) 1377
of innominate artery, case of, (77) 1368
of left subclavian artery, traumatic, produced by fracture of clavicle, (52) 1436
of root of aorta involving walls of heart, demonstration of dissecting, (47) 880
of thoracic aorta, rupture of, (116) 637
of transverse aorta, case of, (29) 1563
of transverse arch, (21) 1045
popliteal, in boy, (89) 1168
racemosum, case of, (62) 1300
thoracic, case of, of unusual size, (138) 340
thoracic, treatment of, by introduction of wire and galvanism, (163) 637
Aneurisms, Matas' treatment of, (18) 684, (132) 689
statistics of operative-treated, (100) 290
thoracic, concerning the symptomatology of, (121) 750, (132) 1117
thoracic, successful treatment of, by iodid of potassium, (14) 689
Angina, complications of, with acute thyroiditis, (57) 1441
diphtheritica und follicularis, (72) 1120
pectoris, infectious (17) 1504
pectoris practical points in treatment of, (32) 280
pectoris, treatment of, (78) 1502
pultaceous, (103) 1502
ulcerative, and stomatitis, cases of, associated with spirillum of Vincent, (88) 934

Angina, Vincent's, (47) 1306
Angioma of placenta, (133) 1508
spinal, (66) 399
Angiomata, multiple, (59) 1368
non-operative treatment of, (95) 996
Anguish, neurosis of, (46) 212
Aniliu dyes as therapeutic agents, (12) 63
Animal extracts, therapeutic value of, (152) 1050
magnetism, exaltation of, (146) 812
suture, the, (97) 637
Ankle, congenital luxation of, (68) 1300
dislocation, (86) 1506
Ankylosis, cicatricial, operative treatment of bilateral, of jaws, *1311
Ankylostomiasis, danger of in coal mines, (77) 139
in Dortmund, (8) 1584
in Scotland, case of, (7) 469
spread of, (3) 1562
treatment of, (105) 693
Ankylostomum, immigration of, through the skin, (80) 290
Anomalies and monstrosities, (30) 1113
Anopheles fuliginosus and sporozoits, note on, (27) 525

Bothriocephalus latus in woman immigrant, case of, (11) 468
Botryomycosis, is there a, (37) 525
Bottini operation, remarks on new modification of, (62) 58
Bottle-fed babies, care of, (35) 132
Bougie-catheter, the, (116) 812.
Bowel, laceration of, without external evidence of injury, (64) 988
obstruction of, relieved by inguinal colostomy, (92) 339
ulceration of, (137) 883
Bowels and anus, benign ulcerations of, (64) 933
and peritonitis, obstruction of, due to strangulated Meckel's diverticulum, (72) 1368
gunshot wound of, (121) 990
obstruction of, (101) 581
Boy's venereal peril, the, *4
Brachial plexus, importance of accurate muscular analysis in lesions of, (2) 1234

Brachymetropia and hypometropia in place of myopia, concerning the terms, (82) 810
Bradycardia as a symptom, (17) 468
extreme case of, (12) 1433
in health, (15) 639
Brain abscess, (65) 1560
abscess, diagnosis of, by means of encephaloscope, (98) 1049
bullet wounds of, (133) 68, (67) 520, (61) 1167
centers, voluntary and involuntary controlling ocular muscles, *1185
diseases, cases of pyogenic and nasal suppuration, (48) 1047
fag and its effect on health, (17) 1433
history of evolution of (56) 133
loss, extensive, without mental impairment, (18) 1112
method for relief of pain in tumor of, (34) 1298
of children, the, (12) 1582
of the Japanese, weight of (109) 291
power in history, influence of, (12) 884
sinuses, hemorrhage from arrosion of, in suppuration of temporal bones, (45) 1299
surgery in epilepsy and congenital mental defect, results of, (3) 876
syphilis, (134) 689
tissue, autolysis of, (64) 1232
tumor with unusual localizing symptoms, (131) 284
tumors, surgical treatment of, (57) 281
Brand, a predecessor of, (171) 69
Bra's neurococcus in epileptic blood, (108) 942
Bread and fruit diet and its effects on high blood pressure, (21) 1229
Breast, climacteric, tumefaction of, (100) 284
milk and cow's milk, comparative examinations of, (23) 517
milk, dosage of, (45) 1119
versus bottle in infant feeding, (95) 1439
Breathing, correct, (157) 812
Breech presentations, management of, (25) 279, (10) 631
Brigg's Infirmary, cases at, (130) 1117
Bright, Richard, (129) 1168
Bright's disease and diabetes mellitus, chronic, (79) 881
disease, chronic, operative treatment of, (2) 1296, (21) 1366
disease, chronic, terminal symptoms of, (66) 1114
disease, dry hot air in, (15½) 1558
disease, dry hot air in treatment of, (30) 1584
disease from clinical standpoint, (9) 285
disease, medical and surgical treatment of, (65) 580
disease, pathology and surgical treatment of, (40) 1435
disease, renal decapsulation in, (88) 1049
disease, terminal symptoms of chronic, (87) 1561
disease, urinary analysis in, (65) 1114
Broad ligaments, cuneiform shortening of, (79) 636
ligaments, pathology of, (99) 586
Brometone, (75) 59
Bromid of ethyl as general anesthetic and preliminary to ether, (15) 884
Bromids, the, (73) 209
Bromoderma pustuio-tuberosum, case of, (50) 207
Bromoform poisoning, fatal, *1540
Bronchial asthma in children, (115) 997
glands, enlarged, (18) 1583
secretions, differential significance of, (141) 529
tubes after measles, dilatation of, (16) 1304
Bronchiectasis in the tuberculous, (8) 1112
Bronchitis in infants, treatment of acute, (116) 1371
Bronchopneumonia, continuous, (53) 212
Bronchopneumonia following throat operations, pathogenesis of, (138) 891
Brother's keeper, am I my? (64) 687
Brown-Séquard paralysis, (76) 881
Brucin, new antidote for morphin, (11) 527
Buboes, suppurating, ablation of, (37) 286
Buccal disorders, general pathology of, (22) 211
expressions of constitutional states, (36) 1367
Budapest, post-graduate work in, (18) 930
Building laws, reform needed in, (25) 137
Bulbo-protuberantial schema, (29) 885
Bullet in knee located by *x*-ray and its removal, (134) 340
in thigh for two and half years, retention of, (21) 341
wounds in modern warfare, (36) 633
wounds of lungs, treatment of, (71) 887
Bulling's inhalation treatment, (87) 343
Bumm, Anton, obituary of, (113) 527
Buphthalmos in subject of congenital dislocation of crystalline lens, (57) 880
Buried animal suture, the, (81) 882
Burn, psychosis after, (85) 818
pathology of, (108) 693
toxins in, (104) 643
treatment of, (161) 1051, (87) 1259
Bursa, suppuration of, over the trochanter major and its occasional imitation of hip disease, (13) 1440
Business aspects of medical practice, (128) 61, (125) 750, (129) 935
methods for a physician, (128) 1168
Buttermilk in infant feeding, (89) 995

Cacodylic medication, (134) 891
Caffein in alcoholic toxemia, (26) 1230
injection as adjunct to bleeding, (21) 1504
Calabar swellings on upper Congo, (23) 1563
Calcareous degeneration of corneal cicatrices, *1084
Calcified bodies, presence of peculiar, in lupus-like tissues, (84) 1116
Calculi, biliary, in cystic, common duct and in anterior wall of gall-bladder, (31) 639
urinary, 292 operations, for, (28) 583
urinary, spontaneous fracture of, (65) 343
Calculus, renal, case of, (154) 936
umbilical, case of, (17) 884
vesical, (18) 286
Caldwell, W. B., biograpical sketch of, (114) 750
California resorts, impressions of, (51) 1501
Callus formation after fractures, (103) 1567
Calorisator in hot-air treatment, (109) 1508
Cambridge Springs, Pa., (104) 1439
Camphor, poisoning by, (40) 579
Canaliculi, ligation of, for extraction of cataract complicated with dacryocystitis (133) 210
Canaliculus, polypus of lower, (88) 521
Cancer, abdominal hysterectomy plus vaginectomy for, (114) 693
and consumption, shall we eliminate, from family history in our application blanks, (85) 1302
cases cured by the cancroin of Prof. Adamklewicz, (38) 691
cases, group of, (14) 1440
causation of, (22) 1118
causation of, and its treatment without operation, (25) 578
caustic paste for, (5) 1582
chemical hypothesis for etiology of, (60) 809
Cancer, choice of methods in, (73) 635
combined pyloric, and phlegmonous gastritis, case of, (22) 1045
cutaneous, treatment of, by Czerny-Trunecek method, (103) 890
electricity for, (128) 284
excision of tongue for, (75) 988
gastric, diagnosis of, (100) 1117
gastric, operative treatment of, (113) 883, (62) 887, (77) 1172, (35) 1236
gastric, prophylaxis of, (93) 1565
heredity of, (106) 1057
in animals, (91) 400, (45) 886
inquiry in Spain, (88) 941
laryngeal, surgical treatment of, (9) 1303
late recurrences of, (130) 347
mammary, (189) 70
mammary, prospects of operative treatment of, (59) 288
of cervix, vaginal cesarean section with, (148) 529
of intestine, (24) 807
of lung, primary, (33) 1230
of omentum, (153) 75 0
of prostrate, (40) 286, (151) 750, (2) 1162
of prostate and selection of cases of suprapubic prostatectomy, (1) 285
of pylorus, case of, (97) 811
of the lip, autoplastic procedure for removal of, (57) 64
of uterine cervix, clinical diagnosis of, (102) 339
of uterine cervix, destructive sterilization by cataphoresis of, *1263
of uterus, stomach and kidney, operations for, (11) 997
pathology and treatment of, (13) 1288
primary, of extremities, (68) 213, (37) 640
primary pancreatic, with multiple cerebral embolism followed by autopsy, (112) 1378
problems of, (4) 396
pyloric, treatment of, (97) 586
rectal, (2) 62, (32) 336, (34) 518
research, (60) 342, (127) 529, (52) 584
Roentgen rays as palliative in, (7) 1496
serum treatment of, (5) 1584
treatment of, by electric osmose, (20) 884
treatment of, by *x*-ray, (15) 205, (93) 339, (47) 393, (43) 1166
treatment of, in pregnant uterus, (91) 586
uterine, (88) 284
uterine, changes in bladder in, (82) 1443
uterine, hysterectomy in, (49) 133
uterine, latest operative efforts directed against, (88) 755
uterine, Wertheim operation for, (39) 207
uterine, relationship of abdominal and pelvic lymphatics to, (50) 1300
uterine, treatment of, (25) 1298
uterine, *x*-ray treatment of, (28) 1366
ventriculi, diagnosis of, (135) 529
vital and toxic theories of, (64) 580
what can be done for, (91) 1561
Cancers, two distinct on same breast, (27) 212
Canteen, the, (24) 1558
Capital operations at St. Vincent's Hospital, (82) 1502
Capsulated bacilli, (61) 754
Capsule, how shall we open the, (79) 810
Caput obstipum, treatment of, (48) 992
Carbohydrates, metabolism of, (101) 643
Carbolic acid in treatment of smallpox, (19) 1235
Carbon dioxid narcosis, (71) 213
monoxid, poisoning by, (71) 933
Carbonated saline waters, action of, (65) 1238
Carbonic oxid poisoning, alteration of central and peripheral nervous elements by, (119) 291
Carbuncle, (143) 936
Carcinoma, advanced, of breast, operative possibilities in, (43) 932
development of, on inflammatory processes, (49) 470
and tuberculosis treated by Roentgen rays, *1406
epitome of history of, (60) 1437
gastric, (56) 337, (122) 1233
hypothesis of Cohnheim concerning (75) 1048
in Munich, frequency of, (91) 1056
in rectum, high, combined method of extirpating, (52) 1306
of appendix, primary, (90) 209
of breast, (33) 1367
of breast successfully treated by *x*-ray, (24) 814
of cecum, columnar-celled, (32) 1052
of cervix, spreading of, (49) 1053
of cervix uteri, (84) 134
of choroid metastatic from prostate, (26) 807
of colon, (11) 1304
of esophagus, etiology of, (141) 68
of intestines, surgical experiences with, (36) 470
of large intestine, operative treatment of (58) 887
of lungs, (118) 142
of pancreas and its diagnosis, (145) 1168
of the tongue, (15) 64, (31) 690
of vagina, etiology of, (85) 642
mammary, treated by mercuric cataphoresis, (13) 1558
parasitic, etiology of, (31) 1504
primary hepatic, (85) 934
primary, of vulva, (85) 135
pyloric, (29) 1046
recurrent mammary, resection of chest wall for, (169) 750
uterine, condition of pelvic lymphatics in, (80) 636
uteri, comparison of vaginal and abdominal methods in, (128) 1508
uterine, operative treatment of, (126) 67
uterine, study of glands in case of, (101) 1378
ventriculi, diagnosis of, (106) 693
ventriculi, notable complications of, (125) 1568
Carcinomata and fibromata, early, of uterus, (157) 936
Carcinosis, universal, hyper and metaplastic hematopoiesis in, (91) 215
with secondary nodule in eye, (27) 807
Card system in gynecology, (42) 807
system in medical practice, (92) 1233, (108) 1371
Cardia closure, muscular, (100) 1173
Cardiac disease, secondary results of, (92) 1439
disturbances, some symptoms by which they can be detected clinically, (129) 812
tonics, (123) 637
Cardiolysis, indications for (45) 1374
Cardioptosis, (9) 631
and its connection with hepatoptosis, (54) 1441
Cardiopulmonary diastolic souffle, (110) 942
murmur, significance of, (18)
Cardiovascular fascia, radioscopy 205
of (102) 942
lesions in children of tuberculous parents, (50) 212
Carditis, case of, (60) 988
of children, opium in, (70) 1560
Carlyle, Jane Welsh, ill health of, (22) 517
Carotid, common, ligature of, in firearm wound of lower jaw region, (137) 758
Carpal scaphoid, dislocation of, (37) 392

Cartilages, growth disorders of, (92) 215
Casein eremata and phosphorus metabolism, (138) 143
Castration, influence of, on blood of female animals (121) 757
Casts in urine, food producing and not producing, (86) 1168
Cataract, clinical lecture on art of extracting the, (76) 810
complicated with dacrocystitis, ligation of canaliculi for extraction of, (133) 210
extraction of, in capsule, (9) 991
extraction of, in Government Ophthalmic Hospital, Madras, (16) 937
extraction, to prevent infection after, (93) 1049
extraction, variations in technic of, (18) 582
in the young, (106) 1050
operations, 1,100, (121) 347
operations, atrophic nasal, (68) 1502
chronic, of large intestines, treatment of, (82) 400
postnasal, (28) 57
spring, (85) 59
Catarrhal affections of upper air passages in children, subacute and chronic, (5) 876
Catatonic symptoms, importance of for prognosis, (84) 755
Catgut ligature and suture material, sterilization of, (10) 129
results with, prepared by very simple method, (65) 817
Catheter, case of retained (109) 990
drainage on function of kidneys, effect of, in interstitial nephritis and pyelonephritis, (27) 1434
Catheterism, retrograde, modification of syringe for (80) 1239
Catheterization of both ureters, simultaneous, (85) 747
Catheterizing both ureters in male subject, method of, (124) 688
Cat's blood, differential counts of leucocytes, (68) 1232
Cauda equina, secondary tuberculosis affections of, (112) 216
Causes of death, co-operative methods for improving usefulness of statistical classifications of, *410
Cavernitis gonorrhoica, (119) 890
Cavities in tibia, treatment of, (40) 470
Cecum, acute inflammation of, (63) 1238
cases of excision of, (15) 639
fecal impaction of, (74) 1502
Celiotomy, vaginal exploratory puncture and, *1404
Cellulitis, acute pelvic, (132) 750
Celluloid as material for flat-foot plates, (7) 743
Centenarianism, studies in, (174) 936
Center for writing, arguments in favor of existence of separate, (95) 934
Central bodies in glioma, (76) 65
nervous system, surgery of, (96) 643
Centrifugalization as test of milk, (18) 813
Centrifugalizing, modified burette as tube for (72) 1308
Cerebellar abscess, case of, (13) 14) 524
abscess of otitic origin, notes on case of, (12) 524
Cerebellum, tumor of, (96) 135, (28) 931
Cerebral abscess, intradural and lateral double, complicating chronic tympanic suppuration, (59) 208
abscess, some points of interest in clinical manifestations of, (20) 64
affections after carbonic oxid poisoning, (129) 143
affections reducing space, symptomatic treatment of, (84) 140
bladder disturbances, (84) 994
cortex, studies on, in normal human brain and dementia paralytica, (101) 990, (36) 1299
Cerebrospinal fluid, circulation of, (22) 1504, (46) 1563
fluid, diagnostic significance of color of, (26) 1236
Cerevisine in treatment of gonorrheal ophthalmia, (173) 62
Cervical dislocation and its reduction, further observations on, (11) 1163
incisions in labor, (47) 519
ribs, clinical significance of, (109) 141, (106) 757
tumors, use of weak cocain solutions in, (1) 1496
vertebræ, traumatism of, (140) 347
Cervicovaginal fistula, case of, (87) 642
Cervix, aseptic dilator for, (59) 139
hydrodilator for treatment of stricture and dilatation of, (48) 1563
dilatation of, according to Bonnaire, (84) 1173
instrumental dilatation of, in last months of pregnancy, (79) 1048
malignant degeneration of stump of, (22) 1440
pathologic changes following lacerations of, (68) 881
uteri, artificial dilatation of, with new instrument, *1338
uteri, circular laceration of, (11) 1296
uteri, laceration and congenital split and erosion of, (131) 1234
uterine, care of, (11) 1582
Cesarean section, abdominal and vaginal, as means of accomplishing accouchement forcé, (46) 519
section and basiotripsy, cases of, (158) 936
section, case of radical, in pregnancy with cervical myoma, (72) 1506
section on dwarf, (105) 637, (9) 1051
section in face presentation, (139) 637
section, limitations of, (163) 1371
section, repeated fundus incision in, (93) 642
section, repetition of, on same patient, (83) 134, (96) 819, (54) 1300
section, six favorable cases of, (48) 1237
section, some curiosities of, (73) 395
section, vaginal, in puerperal eclampsia, (77) 1506
section, vaginal, value of, (162) 1371
section vs. abortion or miscarriage in women with deformed pelves, (115) 812
Chancres and chancroids, (112) 1561
Chancroid bacillus, distribution and culture of, (60) 282
Chancroids, septic infections and nervous lesions following, (19) 286
Changes in ovaries accompanying uterine tumors and vesicular mole, (34) 885
Charcot-Marie-Hoffman type of neurotic atrophy, (51) 58
Charity Hospital, New Orleans, clinic at *238
Charlatanism, (30) 879
Chat with the brotherhood, a, (155) 1371
Cheerfulness in the sick-room, (101) 395
Chemical property, modification of, by partial decomposition of albumin in body, (44) 1441
rays in ophthalmology, theoretical study of possibility of applying, (89) 586
synthesis, process of, in living things, (4) 135
Chenopodium, fatal poisoning by oil of, (116) 883
Chest cases, some clinical, (162) 637
perforation of, from side to side by broom handle, (72) 1564
physical examination of upper regions of, (3) 1234
Chilblains, are they a tuberculid, (35) 137
Child labor, medical and social aspects of, (75) 936
Child life or responsibility to offspring, (109) 523
Childbirths, repeated, in women with contracted pelves, (134) 1508
Children and their teeth, (168) 936
diseases of, due to faulty nutrition, (70) 687
in Colorado, growth and development of, (23) 1434
of what value are drugs in treatment of, (71) 687
rights of, (140) 750
diseases, fresh air in treatment of, (55) 394
Chloral hydrate, large dose of, (62) 1501
Chlorid of sodium, (37) 207, (124) 284
Chloridemia and treatment of Bright's disease by dechloridation, (44) 1171
Chlorids in nephritis, (48) 525
Chloroform administration to man and higher animals, (13) 1562
death or acute uremia, (63) 994
fatal effects of, in children suffering from fatty liver, (12) 285
habit acquired by hysterical woman resulting in death, (14) 397
inhaler, a new, (50) 1368
nose mask, (79) 139
prevention or amelioration of vomiting during the administration of, (60) 338
vapor, rapid estimation of quantity of, present in mixtures of chloroform vapor and air, (2) 135
Chloroma, case of (16) 397
to leukemia, relations of, (91) 65
Chlorosis, (4½) 55, (149) 750
Chloruria, in its relations with pleurisy, (12) 813
Choked disc, (119) 527
Cholecystectomy, cases of, (15) 211
Cholecystitis, acute infections, operation for, in acute stage, (64) 470
typhoid, with calculi, (89) 1116
Cholecystenterostomy, case of, with Murphy button, (28) 987
together with enteroanastomosis, (52) 992
Cholecystotomy, ideal method for drainage in, (20) 468
Choledochotomy, retroduodenal, (62) 641, (40) 1236
retroduodenal, proposed method of, for removal of impacted calculi, (59) 809
Choledochus obstruction, surgical treatment of acute and chronic, (63) 139
Cholelithiasis, (85) 284, (98) 586, (86) 811, (160) 936, (152) 1168
Glaser's chologen treatment of, (153) 1510
oil treatment of, (110) 66
surgical treatment of, (45) 932
value of mineral waters in, (105) 586
with glycosuria, (76) 343
Cholera, diagnosis of, (101) 693
immune bodies, amount of, contained in separate albuminoid elements of the serum, (66) 754
in Manila, fighting, (70) 1168
infantum, atropin in, (169) 936
vaccine, new, (7) 575
Cholesteatoma of cranial bones, (121) 1567
of middle ear, case of, (121) 396
Chondrodystrophia fetalis, case of (35) 1165
Chorea, acute, (82) 747
and athetosis, relations between, (138) 347
complicated by pneumonia, (64) 520
gravidarum treated by inducing abortion, (13) 136
hysterica traumatica, (101) 527
minor, treatment of certain forms of with antistreptococcus serum, (95) 586
Chorea mollis, choreic epilepsy and pseudoparalytic myasthenia, (111) 643
pathology and treatment of, (1) 750
rheumatism, etc., relations between, (67) 887
treatment of, (73) 339, (116) 396
treated by aspirin, (12) 689
treatment of, by ergot of rye, (8) 396
Chorio-epithelioma, (127) 347, (61) 994
and ovarian tumor, (71) 1506
malignum, (96) 1445
Chorionic villi, (29) 1230, (46) 1306
villi, normal anatomy of, (38) 1505
Choroid plexus, pathologic histology of, (93) 1121
Chrobak Festschrift, 1903, detailed abstracts of articles in, (78) 1506
Chromidrosis, black, with hysterical paralysis, (29) 205
Chronic disease, medication in, (59) 691
diseases, treatment of, by physical therapeutics, (157) 1051
Chylous and chyliform effusions, (99) 996
Chyluria, (119) 990, (57) 1114
European, nature of, (120) 143
Chyme analysis, why not absolute precision in, (29) 1366
Cicatrices, new treatment of, (49) 1166
Cicatricial constriction of abdominal wall and left thigh by compression of umbilical cord, (9) 582
deformities in respiratory tract not due to syphilis, (39) 1299
Circular suture of vessels, (70) 526
Circulation, new theory of, and suggestions for treatment based thereon, (71) 1376
of uterus, oviducts and ovaries by x-rays and bromid method, illustration of, (55) 580
Circulus vitiosus after gastroenterostomy, (31) 1309
Circumcision in infancy, (20) 930

Drug addiction, treatment of, (103) 396
business in Atlanta, status of, (98) 990
eruption of iodoform type, (85) 1116
Drugs, abuse of, (54) 208
and their adulterations and laws relating thereto, (93) 811
and whisky habit, (123) 523
of what value are, in treatment of children, (71) 687
pharmacologic action of, *1252, *1255
proper administration of, (122) 1117
Drum membrane in certain diseases of middle ear, exploratory puncture of, (104) 811
Dry hot air in Bright's disease, (15½) 1558
hot air in treatment of Bright's disease, (30) 1584
Dual personality, case of, (53) 393, (140) 523
Dunbar's antitoxin in hay fever, efficiency of Professor, (2) 396
Duodenal fistula, (67) 526
stenosis and tetany treated by gastroenterostomy, (23) 137
Duodenitis, (99) 339
Duodenum, mobilization of, for intervention on biliary system, (54) 641
perforating ulcer of, (61) 635
unilateral excision of, in perforating ulceration of posterior wall of descending portion of duodenum, (55, 60) 641
Dupuytren's finger contraction, (47) 288, (52) 342
Duty of state to unborn generations, (135) 689
Dwarf growth to-day and in the past, (29) 1305
Dyes of aromatic series, study of influence of on digestion, (145) 529
Dysemia, clinical notes on, (66) 580
Dysentery, (129) 637, (76) 747, (126) 812, (42) 992
acute, associated with bacillus dysenteriæ of Shiga, (37) 745
acute, in which death occurred from acute cardiac dilatation, (26) 64
acute, treatment of, *488, (109) 637, (86) 883
amebic, (89) 135, (31) 1367
amebic, in Illinois, with reference to acetozone treatment, (116) 523, (62) 635
amebic, pathology and clinical history of, *476
amebic, study of cases of, occurring at Johns Hopkins Hospital, *480
and intestinal hemorrhage, (11) 285
bacillus in cases of infantile diarrhea, (97) 749
bacillus, the, (3) 1556
bacillary (Shiga's) *242
bacteriologic study of outbreaks of, (83) 636
epidemic, (146) 689, (32) 752, (126) 1233
epidemic, etiology in, (47) 64
etiology of, (82) 1565
malarial, *246
sporadic, successful treatment of, by Aplopappus baylahuen, (8) 638
Dyskeratoses, congenital, and their morbid association, (37) 341
Dysmenorrhea, (161) 637
etiology of, (24) 632
medical treatment of, (19) 684
membranous, (166) 1439
nasal relation of, (55) 1374
new treatment of, (93) 1370
operative, (73) 59

Dyspepsia, pathogenesis and treatment of nervous, (41) 138
surgical treatment of, (20) 524
treatment of, (154) 1371
Dystocia, (74) 581
abnormalities of umbilical cord giving rise to, (55) 988
caused by double congenital cystic kidneys in newborn, *1537
with lacerated perineum, (160) 1051
Dystrophy, progressive muscular, three cases of, occurring in male members of single family, (50) 58

Ear canal, mycotic disease of, (23) 1558
and throat, report of foreign bodies in, (114) 990
cases, everyday, (61) 746
cases, remarks on, (42) 518
diseases in general practice, (39) 987
diseases, suggestions concerning prevention of serious complications in, (54) 988
foreign bodies in, (150) 1050
sclerosis, Trunecek's serum in, (64) 691
speculum with adjustable lens, (109) 66
spontaneous, bilateral hemorrhage from, (102) 811
Early surgical operation, general practitioner and his relation to, (106) 935
Echinacea, (110) 1561
Echinococcus cyst in ovary, primary, (127) 1174
membrane, staining faculty of, (107) 1567
Eclampsia, (142) 211, (5) 805, (45) 1237
etiology of, (139) 1371, (131) 1508
hemorrhagica, (5) 1432
infantile, practical notes on diagnosis of, (75) 687
pathology of, (91) 1502
postpartum, (92) 1502
puerperal, (88) 395, (173) 813
puerperal, before delivery, (8) 1372
puerperal, Bossi method in treatment of, (125) 688
puerperal, cases of, (155) 211, (2) 469, (41) 633
puerperal, consideration of treatment of, (76) 1502
puerperal enormous placenta, (44) 1237
puerperal, immediate delivery, best treatment of, (52) 138
puerperal, threatened, case of, (23) 582
puerperal, treatment of, (28) (132) (60) 520
puerperal, veratrum viride in, (67) 687, (74) 818
studies of cases of death in, (35) 885
treated by hypodermic injections of morphin, (9) 1372
treatment of, (18) 334, (63) 1114, (88) 1561
Economics of the practice of medicine, (127) 61
Ectopia cordis, case of, (14) 752
vesicæ, etiology of, (74) 1564
Ectropion, (134) 135
and entropion, electrocautery incision for, (114) 1371
Eczema, (135) 210, (118) 581
and erythema as seen by general practitioner, (154) 1168
and pruritus, (139) 1050
cured by measles, (19) 1112
infantile acute, (18) 1170
infantile, internal affections and sudden death after healing of, (83) 941
treatment of, (115) 637
Edebohl's operation of decapsulation of kidney, (6) 1044
Edema, case of malignant, (59) 1300
idiopathic, (135) 217
of glottis, (24) 391
Edenberg (von), Karl Langer, obituary of, (78) 343
Editorial work of medical journals, remediable faults in, (71) 338, (139) 812
Education, (115) 135
Education of nurses independent of hospitals, need of institution for, (12) 56
public, relation of medical profession to, (7) 1111
relation of academic to medical (62) 988
Egg, fable of the, (18) 1366
Egypt, how to live in, (141) 1568
the invalid's, (10) 683
Ehrlich's diazo reaction in diagnosis, (127) 757
dimethylamidobenzaldehyd reaction in urine, occurrence of, (92) 934
indol test, (76) 692
toxin theory, new result from, (100) 344
Elastin of infant intestine (70) 1120
stain for, (73) 399
Elbow fractures, straight splints in, (14) 806
Elective studies in the medical course, (111) 1233
Electric baths, (52) 64
baths, influence of on pulse, temperature, etc., (116) 1057
continued current apparatus, portable, (143) 758
currents of high frequency and high tension in chronic pulmonary tuberculosis, (11) 524
light bath, clinical indications for use of, (103) 1117
light, improved, for examining, (73) 1308
light treatment of gynecologic affections, (153) 529
osmose in treatment of cancer, (20) 884
wet packs, (123) 347
Electrical currents of high potential and frequency, therapeutic use of, (120) 339
methods, treatment of malignant disease by, (10) 1234
methods, treatment of tuberculous disease by, (11) 1234
outfit, the physician's and its daily use, (94) 688
Electricity as a therapeutic agent, (128) 1371
in general practice, (13) 1497
in nervous diseases, therapeutics of, (121) 1303
in treatment of diseases of stomach, (26) 517
principles on which is based the therapeutics of, in nervous disease, (6) 1296
Electrocution, accidental, case of, *967
Electrolytic bougie, possibilities and limitations of, in treatment of chronic catarrhal otitis, (81) 395
Electrolysis in urethral strictures, (100) 935
Electromagnet, application of, for removal of foreign iron bodies in bladder, (86) 213
Electrotherapeutics, (106) 1561
proper recognition of, (18) 57
recent advances in, (15) 1045
some obstacles to progress of, (118) 339
Electrothermic angiotribe in removal of hemorrhoids, (1) 1044
angiotribe in removal of large suppurative tubo-ovarian mass, (81) 636
hemostasis with Downes' instruments, preliminary report on, (90) 748
Elephantiasis, case of, (55) 337
of scrotum, operative treatment of, (48) 753
Elevated scapula, defect in trapezius as cause of, (89) 1121
Embolism of aorta as complication of typhoid, (94) 819
Embryo, very young pathologic human, (125) 217
Embryomata and other tumors, (66) 887
Embryotomy, contribution to technic of as applied in transverse dystocia, (38) 1367
Emotions as symptoms, (18) 517
Emphysema, vesicular, (143) 936
Empiricism and medical commercialism, (61) 933
Empyema, (14) 1297
case of neglected, (169) 62
chronic, treatment of, (42) 579
Empyema in children, surgical treatment of, (102) 688
in infants, after-treatment of, (20) 582
long-continued and tuberculous, resection of thorax for, (44) 1374
new method of drainage in, (28) 205
of frontal sinus, *1209, *1265
of frontal sinus with complications, (108) 811
of sphenoidal sinus, intracranial affections in, (52) 288
proposed apparatus for treatment of, (17) 806
report of case of, (98) 581
setonage in, (97) 1302
Emulsion-albuminuria, (4) 1364
Endocarditis, acute ulcerative, (10) 516
cases of, in connection with otitis media, (62) 208
Encephalocele, congenital sincipital, (63) 635
Encephalomalacia, cerebral softening or, (45) 280, (109) 1117
Encephalomyelitis, case of acute disseminated, *1015
Endarteritis obliterans in man of 35, (55) 584
Endocarditis, acute ulcerative, (51) 1114
acute ulcerative, caused by the meningococcus, (38) 745
malignant, (141) 637
malignant, with meningitis, case of, (29) 280
septic, (20) 205
Endogenic infection as origin for eye affections, (97) 819
Endometritis dolorosa, differentiation of, (92) 586
exfoliative, etiology of, (4) 1584
hemorrhagica treated by galvanic current, (79) 818
Endometrium in cases of uterine myomata, condition of, *367
Endothelioma cervicis, (116) 1508
of lymph glands and lymphatics, (64) 399
of mammary gland, (6) 129
Endo-urethral injections, new instrument for, (70) 817
Enemata, nutritive, influence of, on peristalsis, (100) 1309
Energy quotient in newborn, (110) 527
English discovery, the great, (156) 1169
Enophthalmus, traumatic, clinical contribution to, (74) 1561
Enteric fever and infected blankets, (24) 582
fever, dissemination of by dust, (28) 525
fever, generally unknown source of, (27) 1305
fever, spread of, by sewage-polluted shell-fish, (3) 582
fever, value of saline infusion in treatment of, (21) 1235
Enteritis and bacteriuria, (27) 286
chronic, gastric digestion in, (100) 1122
mercurialis, prophylaxis of, (113) 890
Enteroanastomosis, (100) 996
Enterocolitis of infants, (129) 688
Enterocystoma as a cause of ileus, (125) 143
Enterolith, case of, (134) 1050
Enteroptosis, (6) 575, (21) 632, (17) 684
Enterostomy, (20) 632
in selected cases of peritonitis, value of, *74
Entropion, modern treatment of, (118) 210
slight modification of Van Milligen and Hotz-Anagnostakis operations for, (11) 396
Enuresis, contribution to therapy of, (100) 522
epidural injections in treatment of, (124) 757
nocturnal, and adenoids, (139) 891
Enzymes in tumors, (21) 470
mycotic, (3) 389
Eosinophiles, behavior of, in various diseases, (69) 1376
in diagnosis of trichinosis, value of, (5) 929
Eosinophilia associated with dracontiasis, (21) 690
pleural, (10) 813
Epicarin in tinea tonsurans and tinea circinata, employment of, (94) 60
Epidemics, (93) 1302
of contagious and infectious diseases, management of, (93) 1233
Epidermization, methods to hasten, skin grafting, (118) 990, (78) 1302
Epidermis cells in transplanted flaps, survival of, (104) 1567
Epididymis, anastomosis after resection of, (46) 886
experimental tuberculosis of, (106) 942
sterility from obstruction of, cured by operative means, (4) 1044
Epididymitis, acute, in undescended testicle, case of, (27) 280
gonorrheal, treatment of, (60) 1120
Epidural injections, (117) 527
injections, improved technic for, (38) 286
Epigastric pain, causes of, (142) 1371
vessels during puncture, injury of, (83) 1506
Epiglottic abscess, case of, (66) 746
Epilepsia rotatoria, (123) 67
Epilepsy and congenital mental defect, results of brain surgery in, (45) 808, (10) 929
bromid and salt starvation treatment of, (32) 137
daily rhythm of, (23) 335
following a five-grain dose of camphor or monobromate, (116) 581
hereditary factors in, (47) 808
idiopathic, significance of the convulsion in, (26) 744
masked, (135) 1371, (70) 1502
modern treatment of, (72) 1439
operation for, with transplantation of part of ovaries, (27) 470
pathogenesis of multiple angioma of brain with ossification), (69½) 1238
pathology of, (24) 335
statistical inquiry into prognosis and curability of, (9) 63
tendon reflexes in post-paroxysmal phase of, (106) 1174
traumatic, (110) 883
treatment of, (113) 637
what constitutes cures in, (67) 338
what is, (8) 575
Epileptic aura, nature, frequency and possible significance of various forms of, (22) 335
dream conditions, (123) 67
legal and social standing of the (25) 335
seizures, frequency wave of, (10) 1163
Epileptics, care of, (21) 335
state control of, (141) 689
tonic treatment of, (115) 346
Epiphora as initial symptom of Basedow's disease, (54) 880
Epiphysis, deformities and disabilities resulting from injuries or diseases of, (101) 1561
lower, of humerus, traumatic separations of, (3) 1364
upper tibial and lower femoral, growth and architecture of, (49) 887
upper tibial, injuries of tongue-shaped process of, (67) 1054
Epiphysitis, acute, causing a condition subsequently simulating congenital hip misplacement, *305
Epispadias, *297
Epithelioma, (148) 135
conditions that influence *x*-ray in treatment of, (42) 1367
mastoid suppuration accompanied by, (46) 1047
of larynx, two cases of, remaining well two years after operation, (3) 1303
of penis, (104) 1168
of tongue, (103) 522
treated by *x*-ray, (85) 1502
under the *x*-ray, study of histologic changes in, *158

Epithelium cysts, ciliated, in suprarenal capsule and pelvic lymph gland, (73) 399
Eponyms, evil of, *893
Ergot intoxication, eye disturbances in experimental, (147) 529
pharmacologic study of aseptic preparation of, (41) 579
uses of, (39) 686
Erotopath in society, the, (152) 637
Eruption, intermediate between pityriasis rosea of Gibert and psoriasiform seborrheids, (54) 525
Erysipelas, (113) 1508
and erysipeloid conditions, (127) 396, (87) 1302
effect of, on atrophic rhinitis, (29) 685
intravenous injections of colloidal silver in, (8) 1433
migrans, two cases of, (168) 62
migrans universalis in infant ten weeks of age, case of, (166) 62
treatment of, (114) 997, (109) 1174
treatment of by potassium permanganate, (120) 997
Erythema, purpuric, case of, (52) 281
Erythemata as indicators of disease, address on, (1) 396
Erythrea, note on climate of, (20) 286
Erythropleum, (7) 129
Esophagoscopy, (30) 685
Esophagotomy for dental plate, *1410
for foreign body, (130) 1174
Esophagus and stomach, atmospheric pressure in, (116) 401
and stomach, differential diagnosis of affections of, (57) 342
brief summary of surgery of, (12) 683
case of idiopathic dilatation of, (4) 62
dilatation of, (124) 143, (111) 757
diverticula, (26) 1441
diverticula and sound injuries of, (74) 1442
epiphrenal diverticulum of, (74) 692
foreign bodies in, (60) 887
invagination of, into anterior wall of stomach, (74) 754
musculature, idiopathic hypertrophy of, (77) 399
perforation, non-traumatic, (71) 1120
removal of five-cent piece from strictured, (48) 1500
rupture of, from accident, (19) 884
superior results of electrolysis in treatment of cicatricial strictures of, (152) 529
syringe, new, (158) 69
Estivoautumnal malarial fevers, latent and masked, (97) 1561
Ether administration, influence of, on nitrogenous metabolism, (3) 135
drop narcosis in combination with morphin-scopolamin injections, (135) 1568
drop narcosis in gynecology, (133) 1568
improved mask for, (93) 527
instructions to students administering, (114) 812
narcosis, (134) 1568
narcosis, which mask is best for, (84) 642
operating during first whiffs of, (85) 213
vapor, ignition of, in presence of closed electric light, (21) 130
Ethics, medical, (82) 687
Ethmoiditis, acute suppurative, (124) 883
pathology of, reconsidered, (79) 395
Ethyl bromid and somnoform, physiologic action of, (7) 135
chlorid apparatus and method, new, (20) 1170
chlorid in surgery of infants, (125) 1174
chlorid narcosis, statistics of, (52) 641
Ethyl chlorid refrigeration, case of lupus cured with, (34) 137
Ethylendiamine trikresol, disinfectant value of, (157) 637
Eucain, A., intoxication with, (122) 890
Euphthalmin as a mydriatic for the general practitioner, (46) 337
which caused acute glaucoma, (10) 1296
European hospitals, some observations in, (162) 62
trip, medical notes of a, (137) 1371
Eustachian catheter, use of, (126) 340, (80) 395
Exaggerations in medicine, (153) 68
Examinations, systematic, relating to nervous troubles, (142) 689
Excochleatio prostatæ, (75) 1370
Excreta in tropics, disposal of, (1) 936
Exercise, (147) 1371
as mode of treating diseases of the heart, *1197
Exophthalmus and pressure on brain, (61) 1442
pulsans, (104) 290
Exostosis bursata with loose bodies in joints, (22) 814
Experience vs. theory, (48) 580
Experimenta magistri Gilliberti, Cancellarii Montispessulan, (152) 403
Expert evidence, medical, (100) 395, (112) 688
witness, the medical, (105) 1233
Exsection, trigeminal, (47) 1563
Extension apparatus, improvements in, (82) 284
Extensor longus pollicis, rupture of tendon of, (25) 1583
External recti muscles, paralysis of, appearing after blow on skull, (150) 62
Extra- and intra-uterine pregnancy combined, two cases of, (76) 1506
Extracts of organs and malignant tumors, hemolytic property of, (101) 1057
Extradural abscess, mastoid disease and, (7) 1296
Extramedian symphysiotomy, (120) 757
Extra-uterine gestation, clinical lecture on, (21) 1373
Extremities, chronic cyanosis of, associated with polycythemia and splenomegaly, (9) 1433
Eye affections caused by flies, (147) 759
affections, congenital, (65) 1120
and ear service of Memphis City Hospital, notes from, (98) 883
and sympathetic ophthalmia, serious penetrating wounds of, (128) 396
bacteria in, *822
carcinosis with secondary nodule in, (27) 807
changes in relation to renal disease, (12) 991
clinic, an, (151) 285
clinic at St. Mary's Hospital, 1903, (49) 1436
complications attending measles, (54) 1047
complications of smallpox, *645
control of suppuration of anterior segment of, *364
diagnosis and treatment of obscure syphilitic lesions of, (77) 1115
disturbances in experimental ergot intoxication, (147) 529
doctor, an old-time quack, *1142
evisceration of, with implantation of glass vitreous vs. enucleation, (76) 934
experiments on endogenous infection of, (55) 880
experiments to determine value of formalin in infected wounds of, (1) 1432
fixation of, during operation, (19) 991
hitherto undescribed membrane of, (15) 1163
hysterical affections of, (57) 337
inflammations, bacteria concerned in production of, *821
Eye influence of heredity on, (24) 517
injuries, cases of, (31) 1119
injuries of, and their complications, (95) 395
injuries, remarks on, (118) 883
injuries, treatment of, (110) 935
lesions in heart and kidney disease, (7, 8) 1557
localization of foreign bodies in, (73) 521
muscles, traumatic paralyses of, of orbital origin, (24) 397
nerve destruction in, treated by hypodermic strychnia injections, (98) 637
of the needle, modification of, *1413
operations in ancient Babylonia, (54) 342
preparations, gross various methods of preserving and mounting, *761
recent advancement in therapeutics of the, (13) 1044
symptoms, significance of, to general practitioner, (73) 1439
thoughts concerning syphilis of, (150) 812
treatment of syphilitic diseases of, (11) 991
syphilitic affections of, (41) 57
traumas, estimation of working capacity of, (144) 529
Eyeball, congenital cysts of, (84) 521
enucleation of, irritated by piece of steel, (153) 936
prominence of, as method for measuring it, (72) 521
will certain occupations in time affect the cylindrical curvature of, (70) 988
Eyes, care of, during school life, (105) 1439
Eyestrain and civilization, (33) 1046
and functional disorders, (38) 987
and its results, (31) 633
and the literary life, (115) 1117
cramp of ciliary muscle due to, *648
disorders from, (97) 1049
from standpoint of neurologist, (33) 633
from standpoint of physician, (32) 633, (116) 935
lesions in heart and kidney disease, (7, 8) 1557
obscure cases of, (13) 929
some remote effects of, (102) 61

Face, malignant disease of, treated by plastic operation, (38) 1563
pathognomonics of, (93) 141
plastics of, (65) 1054
presentations, treatment of, (91) 527
Facial deformities, injection of paraffin wax in, (19) 524
muscles, irritability of, (21) 391
Faith in healing, element of, (31) 1584
Fall catarrh, (53) 753
Fallopian tubes, concerning nature of small cysts frequently found in peritoneum covering, (53) 519
Family physician, the (43) 393
physician, the specialist and the patient, (33) 932
Farm colonies and sanatoria for tuberculous on Madeira Islands, possibility of, (62) 1120
physician, the specialist and the patient, (33) 932
Fascia, incision of, above symphysis, (82) 1173
Fasciculus of Türck, (58) 399
Fat and parenchyma cell embolism, modification of circulation in, (109) 1122
contained in blood and in certain organs in man, (33) 1504
embolus, (107) 291
formation and disappearance, study of, (37) 138
formation in normal and pathologic organs, (70) 1442
Fat, granular synthesis of, in migrating and pus cells, (82) 1377
in stomach, digestion of, (78) 692
in the oragnism, research on, (75) 65
necrosis of the kidney, *7
subcutaneous feeding with, (99) 1173
Fatigue insufficiency of brain, treatment of, (95) 1378
Fats, influence of, on gastric digestion and treatment of hyperacidity, (123) 217
Fatty degeneration, (72) 1376
Favus, animal and human, (64) 1237
Fecal accumulation, case of, (85) 1168
fistulas, treatment of, (142) 758
impaction in premature labor, (95) 1168
vomit, drowning of patients in, during operations for intestinal obstruction and septic peritonitis, (85) 209
Feces, fragmentation of, (74) 1376
sieve for, (97) 1507
Feeble-minded, state care of, (19) 130
Feeding of infants, artificial, (8) 937, (90) 1168
of infants, differences between natural and artificial, (3) 929
of older infants and children, (4) 129
Fees, collections and deadbeats, (36) 686
Feet, occurrence of painful affections of, among trained nurses, (6) 204, (38) 932
Female generative organs, unique malformations of, (42) 1435
genital organs and nasal affections connection between, (133) 347
urinary tract, tubercular diseases of, (66) 1300
urethra, gummatous affections of, (129) 217
Femora, twists in normal and congenitally deformed, (14) 1558
Femoral artery and vein, simultaneous ligature of, (78) 1239
artery, traumatic aneurism of, (50) 580
vein below Poupart's ligament, consequences of ligating, (54) 887
Femur, delayed union of upper third of, (128) 340
fracture in shaft of, (92) 1168
fractures of, (34) 1499
separation of acetabular epiphysis of, (8) 1117
treatment of ununited fractures of, (105) 523
Fence corner surgery, (119) 1050
Fermentation test, compressed yeast and, (124) 1568
Ferments, coagulating influence of on peptone, (143) 529
Ferraresi's tenoplasty for fracture of patella, (31) 1052
Fertilization, pathogenesis and development, physiology of, (68) 642
Fetal ascites with dystocia, (89) 748
bone affections, (52) 1054
giant kidney and its relation to history development of kidney, (41) 938
heart sounds and umbilical sounds, differentiation of, (37) 885
membranes, pathology of, (36) 1505
Feticide, therapeutic, before the medico-legal society of France, (38) 1119
Fetus in utero, continued development of, after rupture of membranes and escape of liquor amnii, (42) 207, (72) 1115
Fever and elimination of sugar, (53) 1374
in general, management of, *101
increased heat production as cause of, (95) 1309
management of, (81) 1049
Fibroid, case of submucous, complicating labor and puerperium, (163) 936
intramural, (155) 285

Fibroid tumor of left broad ligament, (159) 936
uterus with disease of right ovary and tube, electrical treatment of, (101) 935
Fibroids, uterine, diagnosis and treatment of, (4) 1169
uterine, pregnancy complicated with, (5) 1051
uterine, present position of our knowledge with regard to treatment of, (22) 1373
uterine, removed by operation, (106) 135
Fibroma in jaw, (39) 641
naso-pharyngeal, (44) 1499
of conjunctiva, (107) 1503
of thyroid body, (25) 639
Fibromata as complications of pregnancy, (68) 635, (50) 745, (43) 1046, (44) 1119
Fibromyoma, cystic, of uterus, successful removal of, (68) 208
of vagina, (28) 398
Field service, a new, (16) 690
Fifth Brazilian Medical Congress, conclusion of report of, (108) 1310
cervical vertebra, fracture of, (18) 1563
nerve, orbital route for removal of second branch of, (83) 209
Filaria and mosquitoes, notes on, (16) 524
medinensis, life span of, (4) 285
rapid method of extraction of, (60) 399
Filariasis in man cured by removal of adult worm in operation of lymph scrotum, (3) 1439
in Maryland, (58) 1114
in Porto Rico, (24) 1298
note on, (15) 524
Filigree, improved, for repair of large defects in the abdominal wall, (34) 392
Filling for bone defects, (64) 1505
Filtration, theory and efficacy of, (178) 1051
Fingers, organic sensory and motor disturbances in, (64) 887
Finsen light treatment, something about, (99) 883
Finsen's phototherapy in variola, (149) 689
Firearm wound in left Rolandic region, (36) 690

aid in railroad injuries, (136) 1168
Russia M. D., the, (65) 471
Fish epidemic in Bucharest, (104) 401
Fissure and prolapse of rectum, treatment of, (27) 814
Fistula, (128) 637
and artificial anus, radical cure of, (193) 70
cervico-vaginal, spontaneous healing of a, and of rupture of uterus a year later in another pregnancy, (51) 1237
from appendix to umbilicus in infant, (106) 1567
Hacker's method of treating, (58) 1054
in ano, (65) 1438
plastic closure of vesico-vaginal, (108) 1378
spontaneous vesico-vaginal, (104) 1378
vesico-intestinal, (26) 1045
vesico-vaginal, (159) 637
vesico-vaginal, radical cure of, (43) 280
Fistulæ, incurable vesicovaginal, latest methods of operating on, (56) 342
rectal, treatment of, (45) 138
Flagella staining, (78) 290, (90) 693
Flail joint in shoulder, athrodesis of, (41) 470
Flash lights, (95) 883
Flat catheter for hypertrophied prostate, (36) 286
Flatfoot, (131) 812, (36) 987
and pes calcaneus, (95) 290
plates, celluloid as material for, (7) 743
mechanism of, (39) 470
supports, abuse of, (41) 932
Fleas and plague convection, (33) 1052
Fluids in diet of heart disease, (88) 995
Fluorine poisoning, pathology of chronic, (70) 1232
Fluorescence, arterial, on living human tissue, (29) 417
Fly, exterminate the, (87) 883
Foci, origin of inflammatory, in bones and their relation to ramifications of arteries in the bones, (37) 1374
Food, (69) 59
adulteration, (89) 1369
mineral, animal, vegetable and spiritual kingdoms of, (42) 280, (91) 395
poisoning, the Bhowanipore, (25) 1305
Foods producing or not producing casts, study of, (117) 396, (75½) 635, (85) 1369
Foot-and-mouth disease, report of committee on, (100) 888, (69) 940
case of upward dislocation of, (15) 1170
forcible reduction of deformities of, (56) 816
Forage poisoning, pathology of, (67) 1232
Forceps at the Chrobak Obstetric Clinic, (97) 344
operations, indications for, (36) 1441
Foreign bodies in air passages, (83) 213
bodies in male bladder, (105) 1567
bodies, location of with *x* rays, (85) 887
body in bronchial tube, (39) 1113
body, use of *x*-ray in exact localization of a, (23) 57
Forest mosquitoes and forest malaria, (75) 290
mosquitoes, breeding place of, in Malaya, (36) 992
Formalehyd, (162) 1051
derivative, notes on new, (91) 284
preparations, disinfection value of certain, (89) 693
Formalin, experiments to determine value of, in infected wounds of eye, (1) 1432
in puerperal sepsis, (125) 340
in surgery, use and abuse of, (108) 688
Formol, use of, in histologic stains, (60) 691
Forties, early medical conditions in, (131) 340
Fourth nerve paralysis, uncomplicated, of traumatic origin, (69) 988
of July, 1903, casualty list *547
Fovea, retinal disease limited to region of, *592
Fowl cholera serum, confirmation of experimental efficacy of, (101) 66
Fowler's position in abdominal surgery, (6) 389, (75) 934
Fracture, compound, (42) 1166
gangrene or mortification dependent on lack of skill or neglect in, (138) 135
of base of skull, cases of, (9) 469
of neck of femur in young subjects, (57) 816
of neck of femur, treatment of, (76) 395
of upper arm above condyle, (31) 1236
of upper third of femur successfully treated with plaster of paris without extension, *358
Fractured bones, method of retaining end of, in apposition, (53) 932
pelvis, (32) 885
skull, case of, (90) 284
Fractures, compound, rubber in windowing plaster casts in, (34) 132
influence of innervation on healing of, (190) 70
massage of recent, (108) 527
method of dealing with, (35) 1499
modern treatment of, (142) 135, (19) 986, (75) 1168
of base of skull, prognosis of, (101) 290
of femur, (43) 470
of forearm, treatment of, (89) 140
of leg, fresh, treated by massage and passive movements, (92) 688
Fractures of lower extremity, ununited, (114) 688
of patella, sutured vs. nonsutured, (43) 886
temporary expedients in primary treatment of, (109) 135
treatment of, in country practice, (144) 211
x-ray in diagnosis of, (99) 1233
Fragilitas crinium, cases of, (86) 1116
ossium in insane, nature of, (14) 1051
Frambesia, morula smallpox, Cuban itch, (126) 210
Free body in abdomen, (75) 213
hospitals and dispensaries, means to remedy abuse of, (50) 64
hydrochloric acid in gastric contents, estimation of, (10) 524
Freezing mixtures for preservation and transportation of samples of water for bacteriologic examination, technic of, (71) 754
French Congress of Surgery, report of, (36) 1305, (34) 1373
Fresh air in treatment of children's diseases, (55) 394
Freyer's method of extirpation of prostrate, (139) 61, (26) 690
Friedreich's disease and insular sclerosis, differential diagnosis between, (3) 1162
type of paramyoclonus multiplex, (58) 281
Frontal bone, dislocation of half of, during parturition, (37) 132
Fuller, Dr. Samuel, of Mayflower, (51) 1166
Fundus oculi in hereditary syphilis, (117) 1371
Functional kidney tests, (132) 1568
Funic pulsations, (24) 1164
Funnel chest, cases of, (8) 204
pelvis, (46) 1237
pessary, (53) 939
Furuncles, abortive treatment of, with dry hot air, (172) 69
Fusion center in treatment of strabismus, development of, *898

Gall-bladder and bile ducts, congenital dilatation of, (91) 748
and bile ducts, diseases of, (14) 334
and biliary duct contents, infection of, *1011
and biliary passages, inflammation of, (110) 1050
as source of danger, (33) 280
case of rupture of, (33) 1440
colics without gallstones, (59) 753
empyema of, (9) 752
necrosis of, (62) 139
perforations of, (14) 285
plastic operation on, (100) 942
primary typhoidal perforation of, (87) 209
some freaks in surgery of, (149) 62
surgery of, (102) 1302
Gallstone causing intestinal obstruction, (17) 1366
disease, causes of occasional failure of operation to cure, *1569
disease, treatment of complications attendant on, (69) 1300
disease, few reasons for early operation in, (35) 1230
diseases, causes of failure of operation to cure, (77) 747
into stomach, perforation of, (97) 1565
operation, permanent cures (34) 1236
operations, bacteriologic studies of 46, (91) 290
surgery, points in which Kehr differs from Riedel in regard to, (130) 68
surgery, present position of, (170) 813
Gallstones and gastric hyperacidity, (13) 1365
Gallstones, complete obstruction of first portion of duodenum due to, (47) 1500
diagnosis and surgical treatment of, (29) 64
diagnosis of, (103) 637
etiology and chemical pathology of, (12) 877, (25) 930
evacuation of, by flushing the biliary passages, (75) 1120
history and postmortem notes from case of, (96) 637
in insane women, (88) 135
medical treatment of, (77) 1502
Galvanic battery, Newman's portable, (89) 581
currents, administration of strong, (88) 581
Galvanocautery punctures in tuberculosis of throat, (97) 527
Ganglia of palm, (56) 1054
Gangrene and gaseous phlegmons without septic vibrio, (32) 639
diabetic, of extremities, treatment of, (26) 205
of cecum from distension, (41) 583
of colon and ileum after operation for appendicitis, (48) 932
of female genitals, (37) 1505
of legs, double, following mild attack of enteric fever, (8) 1439
of lung cured by operation, (97) 60
spontaneous, of extremities, (82) 213
spontaneous senile, (122) 347
symmetrical, case of, (83) 1116
Gangrenous folds in intestines, in suture of, (61) 887
Garrisons, potable water for, (20) 1440
Gas gangrene, (74) 994
Gases, history of evolution of theory of, (153) 403
Gasserectomy, technic of, (44) 691
Gastein baths, physical studies of, (78) 1121
Gastric acidity, Benedict effervescence test for, (74) 283
acidity, effervescence test for, (73) 283
contents, inferences to be drawn from examination of, (13) 683
disorders, laboratory diagnosis in, (86) 1233, (89) 1561
functions in splenectomized animals, (81) 471
hemorrhage, (38) 518
hypersecretion, pathology and etiology of, (67) 283, (61) 1307
juice, absence of, (30) 280
juice, digestive activity of, (19) 1229
juice, human, action of, on tubercle bacilli, (106) 643
juice in presence of tapeworm, (124) 1123
motor insufficiency, treatment of, (78) 934
mucosa, histology of pathologic, (55) 1306
patient, physical examination of abdomen of, (84) 1233
secretions, chemical analysis of, (33) 518
spasm, congenital, (39) 1165
surgery, (31) 1563
surgery, notes on, (32) 1563
surgery, remarks on, (123) 61
symptoms, spurious, (42) 1113
ulcer, (76) 283
ulcer, cancerous degeneration of, (51) 399
ulcer, successful treatment of, (157) 285
ulcer, surgical treatment of callous, (65) 526
ulcer, surgery of, (10) 752
Gastritis, chronic, (21) 577
hemorrhagic, due to pyloric lodgement of swallowed laryngeal pseudomembrane, (92) 637
phlegmonosa, etiology of, (141) 695
treatment of some phases of, (140) 637
Gastroenteritis, (127) 1233
water treatment of infants, (79) 1239

Gastroenterostomy, beneficial results of, in irremovable gastric carcinoma, in which pylorus is not obstructed, (5) 62
circulus vitiosus after, (91) 1309
one danger of, (5) 1117
posterior, experiences with, (73) 1172
technic of, (122) 1371
Gastrointestinal affections, general causes of, (146) 529
diseases, methods of treatment in, (61) 988
diseases, 100 cases of, treated at French Lick Springs, (6) 876
surgery, (43) 641, (90) 818
ruptures of, (62) 1307
Gastrojejunostomy for pyloric obstruction, (64) 1368
posterior, new route for, (4) 1117
Gastrophilus epilepsalis larvæ in skin of an infant, (115) 1050
Gastroptosis, (25) 291
gastric contents in, (8) 929
Gastroscope, combined, and gyromele for diagnostic and therapeutic purposes, *1412
Gastrostomy by the Franck method, (114) 935
Gastrosuccorrhea, (55) 1441
Gastrotomies for removal of foreign bodies from stomach, (6) 333
Gastrotomy for 25 foreign bodies in stomach, (21) 1440
Gelatin solutions for subcutaneous injections, (25) 397
tetanus after, (45) 64
treatment of aneurism, (15) 340, (122) 750, (133) 1117
Gelatinous serum, subcutaneous injections of, in treatment of hemorrhages, (49) 64
Gems from practice, (109) 1168
General practitioner and his relation to early surgical operations, (15) 631
practitioner or specialist in medicine, which? (129) 883
practitioner's case book, notes from, (97) 883
Genital canal, bacteriology of, in pregnancy and parturition, (40) 1441
infection, non-gonorrheal, (110) 1233
prolapse, inoperable, new pessary for, (69) 642
Genitourinary clinic, routine treatment of, (24) 1366
disease, aspects of, (23) 1112
organs, experimental tuberculosis of, (23) 286
surgery, recent advances in, (11) 1044
Genius, penalty of, (888) 687
Genu valgum and varum, (149) 1509
valgum infantum, epiphyseolysis with subcutaneous periostomy in treatment of, (134) 402
varum and genu valgum, surgical pathology of, (47) 281, (37) 932
German Congress of Surgery, detailed report of, (58) 213
Life Insurance Societies during 1902, (90) 1565
Preventive Congress, full report of First Annual, (182) 70

tubal, etiology of, (95) 1445
tubular, (41) 1559
twin, diagnostic sign of, (51) 1171
two cases of normal following operation for extrauterine pregnancy, (117) 1439
unusual causes for repeated interruption of, (92) 1445
Pregnant woman, our duty to, (109) 339
Premature labor and accouchement forcé, indications for bringing about, (77) 636
Prematurely born, care of, (74) 940
Prepuce, perforation of, (62) 1505
Present problems, (22) 1366
Preserving and mounting gross eye preparations, various methods of, *761
"Pressure pouch" of esophagus removed by operation, 8 cases of, (2) 340
Preventable diseases, necessity for more careful instruction of medical students in diagnosis of, (94) 1502
Preventive medicine, (136) 637
medicine, future of, *1199
medicine, progress of, (129) 396
Priapism, idiopathic, (76) 1376
of spinal origin, case of, (113) 812
Primula sinensis (daisy primrose) poisoning mistaken for eczema, (106) 1168
Prism sequence for measuring heterophoria, (110) 396
Privileged communications between physician and patient, (36) 518, (16, 18) 744, (78 80) 1233
Proctitis, proctoscopic examination in, (27) 205, (144) 1371
Production of sexes, critical review on laws of, (25) 286
Professional history, half-century of, (132) 340
Projectiles, embolic transportation of, (25) 814
study of effects of, (95) 527
Prolapse of kidney, diagnostic palpation of, (63) 1368
operations, (44) 1505
operations, suture of septum in, (89) 1309
Prolapsus of small intestine and sigmoid flexure per anum, (72) 526
recti, colopexy for, (113) 693
Proprietary remedies, etc., (113) 1168
Prostate and albuminuria, (78) 139
bladder and kidney, treatment of inflammations of, (103) 135
case of enlarged pedunculated middle lobe of, (31) 1046
enlargement of, extirpation for, (5) 1169
extirpation of, Freyer's method, (139) 61
gland, method for removal of, (99) 581
gland, surgery of, (25) 130, (127) 523, (1) 575, (99) 1117
hypertrophied flat catheter for, (36) 286
hypertrophied, surgery of, (43) 58
mechanical treatment of, (88) 526
operation of total extirpation of, (59) 1167
pancreas, diaphragm and spleen, surgery of, (27) 57, (27) 132
Prostate, pancreas, diaphragm, spleen and thyroid, surgery of, (38) 207, (31) 280, (30) 336, (31) 392, (32, 35) 518, (32) 579, (34) 633, (38) 686, (33) 745, (36) 807, (31) 879, (32) 932, (30) 987, (36) 1046, (33) 1113, (30) 1165, (30) 1230, (31) 1298, (34) 1367, (30) 1435, (30) 1499, (32) 1559, (36) 1584
pathologic conditions of, (101) 1233, (93) 1561
postural treatment in cases of hypertrophy of, (83) 284
secondary enlargement of, (79) 1439
surgical treatment of senile enlargement of, (27) 1170
total extirpation of, for radical cure of enlargement of that organ, (16) 64, (2) 285
Prostatectomy, (82, 101) 1233
and galvanocaustic prostatotomy (Bottini's operation), (6) 1163
conservative perineal, *999
Freyer's method of, (49) 753
in U. S., (38) 938
incision, proper perineal, *414
indications and contra-indications for, (164) 637, (31) 685
observed after an interval, cases of, (10) 468
perineal, (54) 337, (96) 688, (27) 690, (128) 1123, (56) 1231, (88) 1233
perineal, partial, (25) 205
perineal, prostatic tractor for, (46) 932
perineal, without opening urethra or bladder, (23) 744
technic of, (152) 62
Prostates, enlarged, treatment of, (36) 132
Prostatic electrolyzer in its time-saving, trouble-saving and curative aspects, (68) 394
obstruction, choice of technic in operating on, (13) 516
obstruction, pathology and treatment of, (3) 285
obstructions, (122) 61
obstructions and their removal, (106) 284
surgery, (123) 812
secretion, constitution of normal, (51) 634
urethra, needle in, (5) 1364
Prostatitis, acute, (119) 1561
acute, after furunculosis, (102) 290
chronic gonorrheal, (121) 1050
chronic, vibration massage in treatment of, (65) 687, (115) 935
Prostatotomy, galvanocaustic prostatectomy and, (6) 1163
Protargol in gonorrhea, value of, (112) 67, (81) 1308
Protective bodies, observations on, and on relation to bacterial virulence, (76) 290
Proteid molecule, construction of, (27) 1046
Protein chromogen reaction with gastric cancer, (97) 401
Proteolytic enzymes, study of, and so-called hemolysins of some of the common saprophytic bacteria, (100) 749
Provincial sanatorium for Manitoba, (126) 1371
Pruritus, eczema and, (139) 1050
Pseudoappendicitis, (40) 641
Pseudoarthrosis, fracture of scaphoid terminating in, (96) 1507
Pseudohallucinations, (117) 291
Pseudohemisystolia and postmortal hemisystolia, (43) 341
Psychiatry and experimental psychology in Germany, (123) 1568
outlines of, (63) 809
outlines of, in clinical lecture, (58) 133
Pseudoleukemia and allied affections, (64) 1564
of skin, (129) 1174
Psoriasis, histopathogenesis of, (37) 1170
secondary syphilis, (142) 62
treatment of, (107) 890
Psychiatric clinic of Giessen, (49) 212
Psychologic side of medicine, (37) 1559
Psychic force, a therapeutic power, (106) 1117
Psychic powers, undeveloped, (122) 339
therapy, (93) 581
Psychology, medicolegal, problem in, (4) 638
Psychoses, best methods of counteracting, due to strain and stress incident to our public-school methods, *1178
experimental studies on pathogenesis of acute, (65) 887
on foundation of syphilis, (133) 529
relation of the public school to seminary and college as to, *1177
study of non-dementing by laboratory methods, (36) 1435
Psychotherapeutics, (18) 1051, (78) 1115
Ptomain poisoning, case of presumed, (22) 884
poisoning, epidemic among Whittier school boys apparently caused by, (73) 988
poisoning simulating smallpox, (119) 883
Ptosis, improved operation for relief of, (25) 991
operation for, (20) 991
non-congenital and hereditary, (50) 753
traumatic, of left eye operated on satisfactorily by method of Gruening, (56) 1368
unusual case of, (52) 1368
Pubic region, disturbances in, in case of flat-foot, (81) 1121
Public health in Japan, (113) 291
health powers, *838
health, relation of medical profession to enactment of legislation on questions, of, (37) 633
health service, (132) 61
school and the growing girl, (114) 523
schools, practical suggestions on physical education in, (15) 1583
should it be educated in matters medical, (120) 1233
toilets in American cities, the need of, (16) 57
Puerperal eclampsia, (34) 57
eclampsia, etiology and pathology of, (66) 134
eclampsia, prevention of, (76) 59
eclampsia, symptoms and differential diagnosis of, (67) 134
eclampsia, treatment of, (68) 134
fever, adjunct to uterine irrigation in, (18) 1304
fever, introduction to discussion on, (116) 1123
fever, prophylaxis and treatment of, (94) 755
fever, questions and answers concerning, (53) 1501
fever treated with Marmorek serum, (136) 284
infection, (112) 339
infection and pseudopuerperal infection, (97) 1239
infection, development of our knowledge of, (12) 1112
infection in private practice, (72) 1168
infection, surgical treatment of, (59) 880
infection, treatment of, (132) 891, (55) 1501
infections, notes on treatment of, (74) 59, (78) 881
uterus, bacteriology of, (118) 61
Pugnet, Jean F. X., (150) 403
Pulmonary circulation with reference to cardiac activity, (101) 61
conditions, *x*-rays as diagnostic agent in, (14) 1234
consumption, early diagnosis of, (153) 523
disease, medical treatment of advanced, (165) 750
gangrene, surgery of, (43) 1559
Pulp technic, notes on, *1574
vasomotor system of, *1523
Pulse controller for narcosis, (90) 527
tension, accurate estimation of the, (55) 1231, (80) 1439
Pulverized metals for surgery, (116) 67
Pupil aberrations, (126) 143
reaction, diagnostic significance of, (116) 67
Pupil, size of, as aid to diagnosis, (117, 125) 1117
Pupillometer, the, (145) 695
Pupils, postmortal changes in, (33) 470
Purification of public water supplies, present status of, *1084
of water supplies by slow sand filtration, *850, *909, *965, *1025
Purifying drinking water, simple and rapid means of, (56) 691
Purin bodies of human feces in health and disease, the, (6) 883
Purpura, cases associated with, (134) 284
hemorrhagica, (105) 141
hemorrhagica and its treatment, (100) 688
hemorrhagica due to ptomain poisoning, (115) 210
hemorrhagica fulminans, (4) 630
hemorrhagica with hemorrhage into brain and death, (52) 988
Pus, (61) 399
only a drop of, (150) 750
Pusey, Dr., biographical sketch of, (114) 750
Pustula maligna, (47) 470
Pyelitis, diagnosis of catarrhal form of, (102) 1057
Pyelonephritis, tubercular, ureteritis and cystitis, case of, (51) 519
Pyemia, collargol in, (78) 1308
treatment of, with iodized milk, (68) 585
Pylephlebitis, (1) 129
Pyloric stenosis of infants, (69) 692
obstruction, (143) 1371
obstruction, gastrojejunostomy for, (64) 1368
Pylorus, congenital hypertrophy of, (120) 581, (17) 1164
Pyocyaneus infection of bladder, (34) 525
Pyocyanose-immun-proteidin, successful treatment of otherwise fatal intraperitoneal streptococcus infection of rabbits by preventive injections of, (95) 693
Pyonephrosis with kidney-colon fistula, *103
Pyopericardium following puerperal sepsis, case of, (27) 1052
Pyosalpinx, double, should uterus and ovaries be removed in operating for, (86, 87) 135, (78, 82) 636, (167) 1371
surgery of, (67) 1300
twenty-two cases of operation for, (136) 135
Pyramidal bundles, functions of and voluntary movements, (50) 1171

Quadriceps extensor femoris muscle, rupture of, (3) 575, (20) 1366
plastic, (76) 1120
Quadruplets, history of case of, (166) 1051
Qualifications to practice medicine, ethics and state legislation controlling the, (111) 883
Quarantine and infectious diseases, (113) 1561
bureau, international, (99) 990
infectious diseases and, (114) 1303
maritime history of, in Louisana against yellow fever, (138) 936
system in Mediterranean, (23) 397
"Quick and the dead," (22) 634, (60) 1560
Quinin, alleged substitutes for, (42) 815
arseniate, dosage and action of, (46) 753
poisoning with, (7) 630
subcutaneously in malaria, (104) 1122
Quinsy, (152) 812

Rabbit-blood postmortem, bactericidal properties of, (102) 1240

Rabies, (13) 576
best methods to prevent, (14) 576
existence of rabic virus at site of bite in child who had died from, (22) 752
germ, Negri's, (67) 994
review of literature on, (11) 576
spurious, case of, (17) 397
symptoms and diagnosis of, (12) 576
symptoms and prophylaxis of experimental, (86) 290
virus inorganism, distribution of, (137) 347
Race degeneration, does hygiene lead to, (74) 1238
suicide, (125) 284
Rachitic deformities of lower extremities, mechanical vs. operative treatment of, (36) 932
absorption of lime in relation to, (81) 994
hitherto disregarded sign of, (83) 343
in monkeys, (40) 138
of lower extremity, osteotomy and osteoclasis in, (37) 470
tardy, and multiple chondromata, (18) 211
Radial artery, abnormality of, (31) 525
nerve after fracture of humerus, results of operations liberating the, (19) 639
Radioactivity, principles involved in therapeutic applications of, (25) 1366
Radiography, an improvement in, (3) 683
Radioscopy, improved technic of, (92) 755
of movements of stomach and intestines and their modification, (94) 1056
Radiotherapy, (103) 522, (53) 686, (50) 1166
in enteritis and colitis, (14) 278
use and abuse of, (52) 208
Radium, (15) 1112, (123) 1303
in cancer, (43) 1166, (123) 1303
in medicine, (4) 1162
phosphorescence-producing properties of, (92) 344
rays, bactericidal action of, (55) 753
rays, research with, (86) 400
treatment of cutaneous affections, (101, 102) 344
Railroad injury to pelvis with rupture of urethra, (117) 812
Railway surgery, emergency character of, and local disorganization from injury, (120) 1439

Uretero-ureteral anastomosis with especial magnesium tube, (112) 643
Ureters, catherization of, (134) 750, (162) 936
Urethra, male, ruptures of, and their treatment, (33) 639
membranous, absolute occlusion of, (46) 1559
opening up posterior end of, through perineum, (34) 1305
railroad injury of to pelvis with rupture of, (117) 812
rupture of, (113) 1378
Urethral calyces, pelves and ureters, paraffin casts of, (49) 932
fistula, incomplete internal, suburethral abscess or, (41) 807
injections, improved technic of, (111) 1123
injections, technic of, (114) 890
muscles, anatomy and physiology of, with reference to treatment of gonorrhea, (93) 1116
strictures, linear electrolysis in, (24) 286
Urethritis, chronic anterior, new method of treatment of, (5) 55
chronic, treatment of, (35) 286
management of acute anterior, of gonorrheal origin, (40) 1166
Urethroperineal fistula, internal administration of methylene blue in diagnosis of, (12) 743
Urethroscope, new air-dilating, *1541
new obturator of, (8) 333
Urethroscopy, illumination for, (33) 286
Urethrotomy, external, treated by continuous retention of a rubber catheter held in position by a "perineal stop," (9) 1562
Uric acid and indican in gout, metabolism of, (87) 400
acid and urates, meaning of, (62) 134
acid diathesis, pathology of, (141) 750
acid in relation to bodily ailments, (110) 1439
acid in urine, new method of determination of, (8) 883
acid, influence of Ems waters on elimination of, (93) 400
acid, transformation of circulating, in organism of man and animals, (3) 203
Urinal, (47) 886
Urinalysis, elements to be considered in, (44) 58
in diagnosis of disease, (128) 883
in pregnancy, significance of, (39) 393
practical points in, (95) 990
technic of, (100) 883
Urinary bladder, extirpation of, (25) 685
calculi, crushing and aspiration of, (92) 290
casts, notes on, (72) 1048
diagnosis, some observations on, (151) 812
retention, treatment of extreme, (96) 581
secretion, obstetric and gynecologic considerations of, (56) 1300
treated with epidural injections, abnormal frequency of, (15) 930
Urine, ammoniacal reaction of, in phosphaturia, (68) 940
casts in, food producing and not producing, (86) 1168
changes in pregnancy and puerperal eclampsia, (38) 807
daily study of foods producing or not producing casts, fatty epithelia and albumin in, (85) 1369
excretion of, after ingestion of fluids, (176) 69
of children, investigations on, (16) 1118
four cases of suppression of, (30) 64
in pregnancy, (75) 818
influence of concentration of, on absence of albumin reaction, (73) 994
intravesical segregation of, (77) 940
local action of on blood vessels, (118) 291
on determining specific gravity of small volume of, with reference to a special hydrometer, (25) 1113
reducing power of in diagnosis, (62) 585
simultaneous appearance of levulose and dextrose in, (100) 527
suppression of, relieved by decapsulation, (125) 523
Urino-pyknometer in determining specific gravity of urine, (25) 1113
Urn burial, plea for, (22) 684
Urobilin, clinical tests for, (111) 693
in stomach, (104) 1173
with carcinoma, (87) 941
Urogenital cancer in its relation to the cancer problem, (86) 941
sinus, persistence of, (6) 1051
Urology, epidural injections in, (48) 398
Urotropin as prophylactic against scarlet fever, (90) 1309
in prophylaxis of typhoid bacteriuria, (89) 215
toxic actions of, (27) 685
Urticaria pigmentosa perstans, (118) 890
Uterine anatomy, (146) 285
appendages, conservative treatment of lesions of, (18) 470
arteries, clamping of, (89) 642
conditions demanding the services of general practitioner, (96) 883
curettage, (145) 523
curettement, dangerous operation of, (3) 1044
displacements, pertussis as etiologic factor in, (63) 933
inversion, etiology of, (114) 757
malignant growths, two unusual, (115) 1508
mucosa, regeneration of, after childbirth, (59) 1171
tumors and vesicular mole, changes in ovaries accompanying, (34) 885
Uterus, Alexander's operation for retroversion of, (52) 1300
and adnexa, tuberculosis of, (3) 1169
and its appendages, conservative operations on, (94) 1049
application of steam to, (36) 885
atresia of, (96) 210
action of, during labor, (94) 748
bilocularis, overstretching of wall of gravid, (75) 1506
didelphis with left hematometra, (42) 1435
Uterus dilator, a simple practical, (60) 139
displacement of, (42) 1231
during labor, rupture of, (170) 750
fibrocystic tumors of, (19) 1045
fibroid tumors of, (140) 1050
how may we cure posterior displacement of, (4) 203
infantile, scanty menstruation, amenorrhea and dysmenorrhea cured by stem pessaries, (173) 1371
injuries of, (57) 139
instrumental dilatation of, (115) 1057
lacerations of, during pregnancy, (48) 584
lateral and retroposition of immobile, (79) 989
management of malignant disease of, (4) 55, (92) 135
observations on pathology and surgery of retrodisplacements of, (22) 286
papilloma, (97) 290
pregnant, extirpation of, in woman of nearly 56, (76) 642
public manual compression of, for postpartum hemorrhage, (56) 399
puerperal, bacteriology of, (60) 880
rational treatment of postpartum infections of, (171) 1371
relation of, to mind, (125) 135
report of case of rupture of, (15) 130
researches on motor function of, (28) 1236
retrodeviations of, (53) 1300
retrodisplacements of, *1193
retrodisplacements of, treatment of, (23) 391
retroversion of, *1189
rupture of, (160) 135, (64) 939, (47) 1237, (107) 1302, (130) 1371
rupture of, and its mechanism, (83) 1173
rupture of, during manual detachment of placenta, (41) 1505
rupture of, in pregnancy and during labor, (95) 688
rupture of, with hysterectomy followed by recovery, (28) 1584
senile alterations of the blood vessels and tissue of, (54) 1171
should it be removed, with ovaries and tubes in double pyosalpinx, (78, 82) 636
suppurating fibroid of, (85) 990
total extirpation of septic puerperal, (86) 140
treatment of prolapsus of, (97) 1370
treatment of retrodeviations of, (24) 524
vesico fixation of, (51) 133

Vaccination acts and prevention of smallpox, discussion on, (1) 581
relation of, to infant mortality, (11) 639
statistics of Metropolitan Asylum Board of 1901 and 1902, analysis of, (11) 582
Vaccine holder, new, (47) 341
preliminary note on use of chloroform in preparation of, (15) 136
pulp, destruction of bacteria in, with potassium cyanid, (14) 684
studies of, (99) 942
Vagina, buried circular ligatures of, in uterine retroflexion, (75) 642
congenital transverse closure of, (136) 1508
transverse septum in, (136) 1508
Vaginal douche, directions for use of, (65) 1167
drainage indications and technic of, for suppuration of pelvis, (168) 1371
exploratory puncture and cellotomy, *1404
fistulæ, (106) 523
glands and cysts, (42) 1505
incision in sepsis following abortion, (47) 207
injections, (54) 64
operating without narcosis, (74) 1506

Vaginal operation methods, technic of, (63) 939
Vaginoperineal approach to rectovaginal fistulas, (19) 813
Vagus, bulbar connections of, (116) 291
Valvotomy, three cases of, (30) 1559
Van Milligan and Hotz-Anagnostakis operations for entropium, slight modifications of, (111) 396
Varicella gangrenosa, (44) 686
with report of an unusual epidemic, (52) 1114
Varices and varicose ulcers, surgical treatment of, (44) 1559
by circular incision of leg, treatment of, (115) 1378
lymphatic, during pregnancy, (17) 669
treatment of, according to Madelung's shelling-out process, (60) 288
Varicocele, operative treatment of, (83) 1239, (151) 1510
suprapubic operation for radical cure of, (24) 684
tubo-ovarian, (41) 212
Variola, (137) 1303
agglutinating, hemolytic and endotheliolytic action of blood serum in, (59) 1232
and varioloid, bactericidal action of blood serum in, (62) 1232
bacteriolytic complement content of blood serum in, (102) 749
course and diagnosis of, (18) 1433
etiology and pathology of, (60) 1232
Finsen's phototherapy in, (149) 689
streptococcus pyogenes in, (61) 1232
Varioloid rash following vaccination, case of recurrent, (8) 524
varicella in Trinidad, (5) 991
Varix of inferior mesenteric vein complicated by chronic ulcerative colitis, *164
Vas deferens, influence of resection on vesical sphincter, (31) 286
Vascular affections, casuistic study of, on nervous basis, (103) 693
tumors, boiling water injections in, (89) 1049
Vasomotor mechanism, disturbances of, as factor in diagnosis and therapeutics, (114) 637
Vassale paraganglin in gastrointestinal atony, (111) 1378
Vegetable poisoning, rapid method of detecting, (103) 1240
Vegetarian diet in gynecology, (56) 139
Veins, dilatation of, (32) 937
Venæ portæ and cavæ, anastomoses of, (113) 346
Venereal disease, combatting, (77) 1121
diseases, (147) 523
diseases and prostitution, (80) 139
disease, prevention and spread of, (86) 687
diseases, contribution to prophylaxis of, (22) 878
diseases, sociologic study of, (48) 1441
disease, some cases of, (103) 1370
diseases, suggestions as to control of, (111) 688
ulcers, diagnosis and treatment of, (70) 143
warts, case of, (19) 930
Venesection, abuses and uses of, (94) 135, (102) 1370
Venom, effects of, on blood corpuscles of cold blooded animals, (39) 745
Venous system, retrograde transportation in, (66) 65
Ventral suspension and ventral fixation for prolapse of bladder with uterus, (125) 61
Ventricular extracystole without compensatory cause, (72) 1442
Veratrum viride, physiologic action of, (83) 818
Vermiform appendix, intussusception of, (15) 752
Veronal, (86) 1173
influence of, on elimination of nitrogen, (106) 1508
Vertebræ, fractures of, (51) 932
Vertical overlapping operation for radical cure of umbilical hernia, further experiences with, *225
Vesalius, side lights on Florentine Academy and Anatomic drawings of, (151) 403
Vibration massage in treatment of chronic prostatitis, (115) 935
mechanical, (28) 807
selective harmonic electric, (124) 1303
Vibrations, mechanical, as physical agent in treatment of disease, (92) 581
Vichy, the station, 1569-1903, (46) 525
Vienna, student physician in, (103) 1439
Villi of human placenta and embryotrophe, cellular-formed elements in, (122) 757
Vincent's angina, complications of, (89) 818
Vis medicatrix naturæ, (158) 1051
Viscera, clinical observations on congenital and acquired transpositions of, (52) 1501
remarkable transposition of, (22) 1563
Visceral inflammations, treatment of some acute, (2) 1503, (1) 1562
Vital statistics, (96) 1168
statistics, co-operative work in registration methods and, *1453
statistics, their value, (131) 61
Vocal cord, local, complete removal of left, for malignant disease, (26) 468
Voluntary movements, (79) 343
Volunteer bearers, training of, and position of regimental medical officers, (5) 689
Volvulus, chronic, of sigmoid flexure, (14) 63
in infancy, (76) 754
in nineteen-day infant, (111) 215
of sigmoid flexure, (56) 288
of stomach, (6) 1227
Vomiting during administration of chloroform, prevention or amelioration of, (60) 338
during rectal alimentation, (4) 340
Vulvovaginitis in children, (103) 1445
prophylaxis of, (36) 1165

Wagner, Richard, the ill health of, *293, *368, (9) 524
Walking apparatus, (78) 940, (33) 1305
Wallich, J., fifty year jubilee of, (127) 68
Wandering kidney, (40) 886
Warren, John Collins, (63) 394
Washing out plan, the, (85) 637
Washington Congress of Physicians and Surgeons, from, (99) 1507
Washtenaw County (Ann Arbor) Medical Society, history of, (119) 396
Water, (126) 284
bacteria, reaction of certain, with dysentery immune serum, (98) 749
borne diseases, (174) 1051
closet seats, transmission of maladies by, (23) 470
courses in China, investigation of, (102) 401
potable, for garrisons, (20) 1440
supplies, purification of by slow sand filtration, *850
supply and sewerage of Buffalo, local conditions of geography and population as bearing on, (47) 337
supply for landing parties and naval brigades, (1) 689
supply, how city should protect its, (53) 988
supply of City of Columbus, chemical analysis of, (175) 1051
Water supply of Columbus, bacteriologic analysis of, (176) 1051
supply of Columbus, what is present, (177) 1051
Wattenlaufen—a new therapeutic snort, (59) 1306
Weakly children, artificial feeding of, (126) 1123
Western Texas for care and treatment of consumptives, adaptability of, (109) 688
Westphal's sign in croupous pneumonia in children, (65) 1376
White, Charles, the obstetrician, (13½) 1170
corpuscles, thermotaxis of, (144) 758
"White-spot diseases," (53) 281
Whittier, the poet, ill health of, (104) 990
Whooping cough, (22) 57
cough, double optic neuritis complicating, (86) 521
cough, fatality of, (69) 1168
cough paroxysms treated by pulling the lower jaw downward and forward, (80) 59, (41) 1046
cough, present status of treatment of, (82) 1308
cough, transmission of, by indirect contagion, (25) 987
cough, treatment of, (139) 284
Widal's reaction in icterus, (87) 755
Wifehood and motherhood, effect of higher education of women on (106) 1502
Wilde incision, inefficiency of, (41) 1299
Window resection operation, the, *1391
Winkelmann's operation for hydrocele, (56) 470
Wintering of children, the, (136) 523
Winthrop, Jr., J., Governor of Connecticut as a physician, (61) 1437
Wire saw, instrument for introducing, (109) 215
Wiseman, Richard, Sargeant Chirurgeon, in 1676, English surgery as practiced by, (23) 878
Witzel's ether-drop-narcosis, commendation of, (47) 138
Women, brief observations on some conditions in, that are of much concern to the practioner, (119) 1303
in medicine, (122) 527, (92) 1302
of to-day, causes of ill health of, (128) 688
Wood-work factories, injuries as seen in, (153) 211
Woodworkers, diseases and accidents of, (51) 816
World is idea, the (158) 812, (164) 813
Worm infections, differential leucocyte count in, (5) 1439
Wound infection, skin as source of, (41) 518
Wounded in wars of 15th and 16th centuries, (34) 640
Wounds, accidental, experimental study of increase or diminution of germs in, treated by aseptic and antiseptic methods, (35) 583
closure of, *219
how to close, (118) 1117
Wrist, experiences with injuries of, (118) 1567
Wry-neck, new treatment for, (60) 1114
Wyman, Morrill, memorial meeting to, (17) 631

Xanthoma, certain form of, (1044
Xeroderma genitodystrophica, (97) 643
Xerophthalmia in infants, (115) 1123
Xiphosternal crunching sound, (76) 521
Xiphothoracopagus, operated on, (107) 1174
X-ido bismuth, (98) 1561
X-ray as a therapeutic agent, (119) 339
burns, cream paste for, (103) 522
burns, septicemia and death following, (51) 393
X-ray, cases treated by, (14) 390
importance of, (164) 1051
in fracture of shaft of femur, (92, 93) 1168
in kraurosis vulvæ, experience with, (27) 391
in chronic eczema, acne, and cancer, uses of, (104) 637
in treatment of epithelioma, conditions that influence use of, (42) 1367
observations on therapeutics of, (46) 1166
shields, (115) 527
technical management of, (98) 1233
therapeutic uses of, (97) 210, (78) 747
therapeutics in skin diseases, observations on, (16) 1229
therapy, (90) 581
therapy with report of a case, (54) 1231
treatment of malignant disease, (48) 1166
two tumors benefited by, (54) 686
what is the, (97) 1233
work, observations on, (45) 1166
X-rays, action of, on physical organization, (33) 336
as therapeutic agent, (34) 336
cell division under, (86) 343
effects of on living tissues, (64) 282
in treatment of malignant growths, (82) 339
in treatment of skin diseases, (1) 985
present status of therapeutic uses of, (108) 135
therapeutic uses of, (78) 1439
what are the, (11) 204

Yeast and formalin in gynecology, (96) 344
compressed, and fermentation test, (124) 1568
fat substance of, in therapeutics, (128) 694
in experimental infection, (73) 1055
Yeasts pathogenic for animals, study of, (63) 754
Yellow diazo, (115) 643
fever, Americans and, (44) 212
fever and mosquitoes, (22) 690
fever bacillus in peritoneum in experimental infection, behavior of, (114) 1378
fever, discussion of prophylaxis of, at Fifth Brazilian Medical Congress, (126) 1174
fever, etiology of, (12) 752, *1340
fever, experiments with transmission of, by mosquitoes, (124) 1174
fever, glucosed artificial serum in treatment of, (119) 1174
fever, history of maritime quarantine in Louisiana against, (138) 936
fever, hyaline cells in, (102) 1310
fever in Havana and Cuba, (154) 62
fever, mosquito only way of transmitting, (95) 284
fever, report of committee on transmission of, by clothing, (105) 1310
fever, segmentary arrangement of certain cutaneous symptoms in, (121) 1174
fever, some cardiac symptoms of, (106) 1310
fever, transmission of, by mosquitoes, (114, 124) 1174
Yohimbin, (87) 140
as an anesthetic, (88) 343, (121) 527
Yosemite Valley, 1901, pioneer resident physician in, (20) 334

Zeitschrift (f. diet u. physik. Therapie), first five years of the, (161) 69
Zinc glyco-gelatin, improvement of, by dusting with powder, (117) 890
Zomotherapy in tuberculosis, (98) 60
Zone formed skin diseases, chronic, (75) 994

CURRENT MEDICAL LITERATURE

INDEX OF AUTHORS

This Index includes the names of authors of articles which have appeared in this journal, as well as of those listed under Current Medical Literature. This practically includes the names of all who have published articles in the leading journals of the world. The * preceding the page reference indicates that the article appeared in full in THE JOURNAL.

Aaron, C. D., (133) 135, (18) 1558
Abadie, J., (37) 525
Abba, F., (91) 888
Abbe, R., (23) 578
Abbott, A. C., (100) 749
